UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF  
COMMANDER ANTHONY RODGERS

Kensington, Maryland  
Friday, September 5, 2003

## PROCEEDINGS

INTERVIEWER: I'm at the Naval Special Clearance Team (NSCT) One in Coronado, California with the commanding officer, Commander Anthony Rodgers. Could you start out by giving me a short summary of your career as a Navy diver?

COMMANDER RODGERS: Sure. I graduated from the Naval Academy in 1983. I went to SWAS and then to dive school. I graduated from dive school in September of 1984. Then I went to the USS *Kansas City*. I was on the *Kansas City* until 1986, at which time I went to Underwater Demolition (UD) School. I graduated from UD school in September of 1987. I then went to Explosive Ordnance Disposal (EOD) MOB Unit 2 at Fort Storey, Virginia.

I had an area search detachment, which was initially in the Mine Countermeasures (MCM) department. Then I took a team of battle group divers and EOD on the USS *Theodore Roosevelt* on her maiden voyage in 1989. Then I had an MCM detachment in 1989. 1988 was spent on the Theodore Roosevelt. I did most of my diving as an MCM detachment as an officer in charge. I extended a year. I was there for three years so that I could get Rota and have an MCM detachment. Being in mine work there had great appeal to me to. I've been lucky enough to actually trail through in and out of mine warfare throughout my career. I think it helped, in addition to the timing of the commissioning of this unit, that I had sort of dabbled in mine warfare throughout my UD career.

From MOB Unit 2, I went the Detachment in Rota, which wasn't really an MCM unit at the time. I was there for two and a half years. Then I went to PG school. My thesis was related to mine warfare. I went from there to MOB Unit 6 as the executive officer. At the time, MOB Unit 6 was a dedicated MCM or UCMCM command. That was our focus.

From there I went to 5<sup>th</sup> Fleet as the mine warfare EOD officer on the 5<sup>th</sup> Fleet staff. After the 5<sup>th</sup> Fleet, I went to VEO Mine Warfare, which was in the NAVSEA program office, which dealt mostly with surface MCM systems and C4I. It was at that time the decision was made to commission NSCT-1, which we did in September of 2002. That's my career. Since September 2002, I've been here at NSCT-1 getting us on our collective feet.

INTERVIEWER: Your whole career has basically involved mine issues?

COMMANDER RODGERS: Yes. I would say that since EOD school, I've had something to do with mine warfare. Even at the Detachment in Rota, even though we didn't have an MRCI or anything back Then all the short attachments had a limited mine warfare capability. We did some operations with the Royal Navy divers. They would come to Spain and do MCM exercises with us, as well as doing some stuff with the Spanish. It was sort of an introduction to coalition MCM and how the Royal Navy did their MCM diving.

INTERVIEWER: How does the mission of NSTC-1 differ from traditional EOD mine countermeasures?

COMMANDER RODGERS: Well, the notions behind commissioning NSCT-1 were free amphibious landing and mine and obstacle clearance. The command was a consolidation of what was before the VSW MCM detachment, that is, the very shallow water mine countermeasures detachment and the two other marine mammal systems, Mark 4 and Mark 7. The very shallow water mine countermeasures detachment started in 1996. It took a while after Desert Storm to digest that we did not have the capability to, in a clandestine manner, clear mines and obstacles in the very shallow water region, which is doctrinally defined as the depths from ten feet out to forty feet. In reality, it's from outside the surf zone, wherever that might be, to as deep as your rigs or your equipment will allow.

What we have really evolved into is from outside the surf zone to the horizon. That's our goal. That's our mission. Some of it is sort of self-defined because we certainly can't clear Q routes from the horizon as a single command, or routes from the horizon all the way up to the surf zone. We don't have the resources to do that in any amount of time. But we can provide a safe route for our own systems to get into where the boat lanes would begin for an amphibious landing. The reason we were commissioned was to consolidate some of the deeper water MCM systems, that is, the Mark 4 and Mark 7 marine mammal systems. Mark 4 is the system that finds moored mines in deep water. Mark 7 finds proud mines and buried mines in what is termed 'shallow water', but it's sort of between VSW and very deep water. The difference between an MCM detachment and us is that we are 150 strong and we specialize in the very shallow water area.

We have Navy EOD techs. We have Navy SEALs. We have reconnaissance Marines. We have special warfare combat craft crewmen. We have mammal handlers and first and second-class divers. I have a submariner who is sort of a calico of specialties that were selected to enable access for the amphibious force, given that mines and obstacles are likely.

INTERVIEWER: Tell me about your first real operational deployment, to Operation Iraqi Freedom.

COMMANDER RODGERS: It was a great opportunity to assess what it takes to get us from Coronado to the fight. I don't want to call it an exercise. It was an operation. It took three C-5s to get us over there. We did an exercise in January of this year to practice. After the exercise was when we could sort of tell how many boxes, how many cages and how many pallets it was going to take.

Before the exercise, we thought it might take as many as five C-5s to get us over there. We didn't want that to be true. So, we kind of pared ourselves down. I think we could probably get smaller for the next deployment. But it was a great opportunity to get up and move basically everything we have except for one of the marine mammal systems. We took nine dolphins. We took six Unmanned Underwater Vehicles (UUV). We took everything that gets in a boat and does operations with us with the exception of the Mark 4, because we didn't expect deep water mines. That wasn't going to be our operational environment.

It was significant because it wasn't very long prior to that that we were actually commissioned. We didn't start from zero. The SW MCM detachment existed before and so did the Mark 4 and Mark 7. But we hadn't integrated them and we certainly hadn't taken nine animals anywhere, in addition to all this. You know, the mission of harbor clearance was not something that we were terribly familiar with since 1996. We had been practicing diving against an opposed beach, which happened not to be this mission.

Anyway, the deployment was an eye opener for us, I think, in terms of the urgency to clear water. We expect that sort of urgency before an amphibious landing. We didn't expect it for clearing a harbor for humanitarian aid delivery. We thought that we'd have lots of time. We thought it would basically be a benign environment. Neither of those turned out to be the case. It was not the deployment designed for NSCT-1, or for what we were commissioned. But it was a great opportunity to pick up, get over there, operate and come home. Now we're just digesting all the lessons as to how to do it better next time.

INTERVIEWER: How hard was it to transition from the mission for which they had been training for years, you know, the mission of clearing amphibious assault lanes to attempting to clear a harbor instead?

COMMANDER RODGERS: In terms of difficulty, it was not difficult. I would consider harbor clearance a subset of our capabilities as we train to clear boat lanes. The normal training regimen is that you do everything at night. You do it under cover of darkness. You do it loaded with lots of weapons, expecting to encounter perhaps some kind of surface force out there. You come with an insertion craft from over the horizon, get put in, stand in water for three hours, at least from a diving perspective, come back up and go back out to the ship. It was not that at all.

It was basically setting up on the beach. As I said, there was a fair amount of urgency. There were heavy currents that we were subject to diving around. We had to wait for slack water periods to do that. Nobody was shooting at us when the whole command landed in Umm Qasr. We had a lead party that had a couple of little skirmishes, but nobody was in really serious firefights except for one guy for one day. Comparing to how we'd been training for those years, it was actually, operationally, I think, easier. What we weren't quite prepared to do was set ourselves up in a forward operating base on the beach.

We found a warehouse. Initially, we didn't have cots. We didn't have tents. We had done a little bit of practice as to how to work from a forward operating base. In terms of good solid communications and the infrastructure that you would have if you were used to going forward and then setting up on land, we've always practiced and had the ship as our home base.

When you are done with the mission you go back to the ship and that's where your planning spaces are. That's where your communications are. That's where everything is. It's a ship. We have been using ships for a couple hundred years and we know how to work from them. Working from the beach was one of our main lessons. We are now better prepared to go into a harbor, to be helicoptered in and work from there with the tents and the com sweeps and all that stuff that is really expeditionary.

INTERVIEWER: What about the mammals? The transit time was without stress for the animals, right?

COMMANDER RODGERS: It was. I think the mammals went really well. It's funny because when we were written into the planning order, right after we were commissioned, I made a visit to 5<sup>th</sup> Fleet. Its desire was for us to go over and be part of the plan, but they didn't want to bring the dolphins. They knew that the dolphins were going to be a pain in the neck, in terms of logistics. They are very logistically intensive.

However, the handlers at this command, the support from SPAWAR, the veterinarians, the tech reps and all the folks who thought about the logistical requirements nailed it. They covered everything. There was never a time when, you know, we were in a condition in which we thought an animal was in danger except for a couple of times when they ran, and that does happen. But the 5<sup>th</sup> Fleet didn't want to have to deal with the dolphins. It knew we had dolphins. The 5<sup>th</sup> Fleet people knew we had UUVs and they were thinking, "Well, it's a much smaller package. It's a much easier package." They said, "We want you guys, but don't bring the dolphins."

During my visit, the point that I made was that we had been feeding these dolphins restaurant-grade mackerel for thirty years and we had never taken them to a mine campaign. We had never had them hunt mines in a real scenario and the environment was tailored for it. We thought we might be working in the river. Ultimately we didn't, as a command. But the plans showed the Port of Umm Qasr. The plans showed the river. We thought, "This is tailored for dolphins. If we don't bring them to this one, why do we have them? We should just let them go, sell them to Sea World or do something because this is really what they are there for." If they are

too much of a logistical pain to bring to a theater of war, it's just not worth all the effort that goes into them.

Whether it was that argument or the fact that dolphins are the only ones that can find buried mines, and the likelihood of buried mines during the planning stages was pretty high, or the combination of the two, the powers that be were convinced. They said, "Okay, bring your dolphins." The one issue with the dolphins that we advertised was that when they were to fly over there, at a distance like that, we wanted to have an acclimatization period. Seven to ten days was what we advertised. They get off the plane and go into what we call a 'Miller pen,' which is a pen that is set up in open water. The dolphin is worked every day out of that pen for a week or so, so he gets used to the water temperature, the salinity, and the environment in general. It's a new place for him. He can get all the vibrations of the plane out of him and all that other stuff. After that period, we can embark the ship and be ready to go to war.

Well, the tip bid was running about a week and a half behind. The theater commander wanted to say that he was ready to go but the dolphins were not there yet. Our flight kept getting pushed back because the normal tip bid delay was affecting us, as it was everybody else. When it came to the point at which it was about two weeks behind, he said, "Okay, look, when these dolphins come you're just going to get on the ship and you're going to the nag and waiting until you get called in." Against our objections, the thought was that we would go there and still have some time to acclimate them up there. We were to set our pools up in the well deck and then work them out of the stern gate. The thought was that they could be up close to where they were going to be working anyway.

Well, that posed to be sort of a problem because one stern gate and nine dolphins is not a reasonable way with which to work them. We did that. The dolphins flew over and they

embarked directly on the USS *Gunston Hall* and we got underway. It was basically a one or two-day operation. We were underway, trying to get them in shape. When they're in pools, which are these twenty-foot wide pools that are about five or six feet deep, they just aren't as content. It's harder to get them motivated. They're just kind of swimming in circles. You try to get them out every day to work. But with unrep schedules, a couple of bad weather days and just trying to work boats from a stern ramp and get nine dolphins out every day, it didn't happen.

When it was time to start, we had four dolphins that we thought were ready. In that period of work-ups, which was actually for about two weeks while we were up in the northern Gulf waiting to get the call, one of them ran for about five or six days. It was Heffy. At the time, it was considered a mine threat area. It wasn't a minefield. It wasn't a mine danger area because no mines had been found. But it was considered to be an area that might be mined and just a dangerous area. The possibility of suicide boats was in some of the intelligence reports. It wasn't an area in which you wanted to have to leave a boat in the water overnight with the pinger in the water, hoping for the dolphin to come back. It caused us a little bit of stress.

After five or six days, the dolphin did come back. We got him. He had lost a bunch of weight. But after that, there were a couple of dolphins that we didn't even want to put in the water, because we were afraid they were going to run. It took up man-hours to sit in the boat when in fact we had to get these dolphins ready. The same thing applies to acclimatization. We had four dolphins that were ready to go. When it was time to go into the port, we sent in by helo all the pools and stuff to set up before we could send the dolphins in.

Again, it was logistically covered without a hitch. The tech reps had taught our guys how to set a pool up, but they knew how to do that already. It is kind of like your swimming pool at home. You fill it up, shock it with a bunch of chlorine and then re-treat it after the chlorine has

worn off. You re-treat it to the salinity, the temperature and basically everything that is ideal for the dolphin. Then you call the dolphins in and they come in on the helo and you put them in the pools.

It worked fine, but it is a lot of baggage to use these systems. But we did use them successfully. I say successfully. We got them over there and they calibrated fine. We didn't find any mines in the water. To answer the question, it was stressful for the dolphins, but it worked out fine.

INTERVIEWER: You didn't find mines because there weren't any there. The dolphins were able to verify that the port was safe and that allowed the humanitarian material to flow through the port?

COMMANDER RODGERS: That's correct. They were not, certainly, the first sensors in the water. When we got the call to go in, the first sensor in the water was the UUVs. The system we used was the Remos. It looks like you talked to Staff Sergeant Durand. He probably gave you a pretty good overview of how that went. Had we not suspected that mines might have been buried, we wouldn't have used the dolphins, because the resolution on Remos gave us a good picture. We got a good picture from the side scan that is on the UUV.

We painted the bottom with the UUV. Anything that might have looked like mines on the screen we put divers on. The divers also went in on the piling of the piers and they did a jackstay about five yards out from it because we suspected that the dolphins wouldn't go right up to the pilings. Sometimes they get a little skittish about going right up to a seawall or a set of pilings if it's an area with which they are not familiar. We did a jackstay the length of the seawall and reacquired any of the contacts that the mine-like contacts that the UUVs came up with. We used the dolphins third in the areas where we thought the bottom was soft enough, based on the

divers' report. That was where a mine would be buried completely if it were thrown over the side, either from a truck driving up to the pier and backing up and dumping mines or a vessel that had floated up and dropped the mines there.

We did find patrol boats that had mines on them and boats with empty spaces where mines might have been before that. There were plenty of indications that there might be mines in the water. We did what we consider a thorough search to determine whether or not there were mines. As you know, exploratory hunting is what you do until you find one. Once you find one, you pull out the fine-toothed comb and you really look hard. Well, exploratory hunting has proven to be a method that tells you whether you have mines. That's what we did throughout both the ports of Umm Qasr and Az Zubayr, and we never found one. I would say the dolphins did their job. They didn't find any mines. We haven't heard a boom yet. It's been six months since they did their work, so I expect that there really aren't any mines there.

INTERVIEWER: That's good. Tell me about the UUV, sir.

COMMANDER RODGERS: The UUV is the thing that has gotten the most attention since the end of the war. Divers and dolphins do not give you the picture of the bottom that the UUV does. It's a really nice thing to have. The resolution, like I said, provides you with a high probability of detection and, under such conditions like that which we had at Umm Qasr, it gives you adequate coverage for exploratory hunting. For the NSCT 1 mission, we used the UUVs first. If we are approaching a beach for an amphibious landing, the optimal solution for mine countermeasures is to avoid where the mines are, not clear them. That process is slow, loud and hard. If you can paint me a picture of where I am and where I want to go and I can look at the picture and say, "Well, let's make our route over here where there aren't any mines," then that's what I want to do.

There is an idea and sort of a mantra coming out of the war effort with the UUVs. If we can have the capability to find buried mines with these things and we can make the capability to place charges when we do find mines, that's when we really start talking about getting the man out of the minefields. Divers and dolphins will be replaced when these UUVs can find mines reliably. They didn't find any mines either, so they are sort of unproven in that way. But when they can find them, lay charges on them, and have a couple of other capabilities like being able to find buried ones, we'll be able to use them exclusively. We do need an obstacle avoidance system and a couple of other things. But this was the first operational use of the UUVs and that very quickly became recognized by the commander of the 5<sup>th</sup> Fleet. He was aware that we had those and called us away to do another job, to search a lake for a pilot who had gone down in that lake. Like I said, it very quickly became recognized that this is a very small package and logistically at the opposite end of the spectrum from dolphins, or divers for that matter. Today, though, we still need both of those systems to do a search.

It's sort of like the side-scan sonar that you tow, but you don't need the boat. All you need is a little rubber boat or if you can run it from the shore, you don't need a boat. It is programmable and you run it and do your search. You know, we fit people, UUVs, processing equipment, food, and water in one 53 helo. We fit enough stuff to do a job for two weeks, and packed it up in a couple of hours. It was really nice.

INTERVIEWER: That's a new precedent.

COMMANDER RODGERS: Yes. Going a high clutter area, Hawaii, for example, and looking for mines among coral heads, is something we are not so sure we are ready to do yet. On an amphibious mission, we call it a 'bottom characterization tool.' So, we paint that picture of the bottom of the beach as wide as the tool can and then show that to Kadiff and Cliff. We say,

“Okay, it’s really smooth over here and it doesn’t look like there are any mines, but it’s really cluttered over here. It’s going to take us longer to clear in this area. Let’s pick our boat lanes where it’s nice and smooth and easily huntable and try to generate that discussion between Kadiff and Cliff. Get the word to them. Okay, let’s put the boat lanes here and then go about our business with dolphins and divers.” Hopefully, in five or ten years, or whatever it takes, we can put another UUV that, in and of itself, will find the mines and put charges on them. We’ll be good to go.

INTERVIEWER: Someday, Special Clearance Team 1 might be a lot of sonar techs and very few divers.

COMMANDER RODGERS: That’s correct. Yes.

INTERVIEWER: Do you think that's where the future will go?

COMMANDER RODGERS: You have the Expeditionary Strike Group, the first of which just deployed about a week and a half ago. I think battle groups and ARDS, if that is what they are called, maybe we stick with the Expeditionary Strike Group, but whatever it is, this group of ships goes forward as the fighting unit afloat. I think that ultimately, NSCT 1 will probably be out of a job. They won’t need to fly us away to do things.

When the reliable capabilities are completely contained in UUVs, that is, detection, classification, identification and neutralization, we’re going to put those UUVs on ships forward. They are going to be in the battle group through deep water. They are going to be able to go in laterals or whatever, and you will train your sonar techs that are already on those ships how to use these things. We should be out of a job. It’s kind of a matter of time. It might be twenty years, but I don't know.

INTERVIEWER: In the meantime, though, this is a pretty good place to be?

COMMANDER RODGERS: Oh, it's a great place to be. It's an unsolved mission. We think we have a pretty good set of tactics for how to do it. We're coming up on a year of a fair number of exercises, the main one of which will really allow us to pull out all the stops and have our coming out party in June of next year. Basically, we'll test all these lessons that we learned, both in Operation Iraqi Freedom and the logistics and tactics that we have been practicing in the water here in San Diego in the amphibious role, but not necessarily harbor clearance. Can we get across the beach and either avoid or clear everything that's in the way in a reasonable amount of time for the Marines to get ashore?

INTERVIEWER: That's going to be in June next year?

COMMANDER RODGERS: That's right. It will be in June at Camp LeJeune.

INTERVIEWER: Right now, your unit's made up of mostly EOD techs, SEALs and Marine reconnaissance divers?

COMMANDER RODGERS: I'd say we're about two-thirds second-class divers and fleet technicians one-third that type of person. I don't like to use the term 'support,' but SEALs, Marines, and EOD techs make up about a little over a third of our present manning. The rest of the people are going in the water so much, diving on mines. We have guys who are mammal handlers and guys who run UUVs. But the only way we have today to clear the mines is with a diver and a charge. Those other systems are search systems and a human does the neutralization. That makes up about a third of our guys.

INTERVIEWER: How does that mix of people work out for you?

COMMANDER RODGERS: It works surprisingly well. You know, it's a pretty congenial bunch. I think it is composed of fairly senior folks and so they are much more likely to bring

their strengths to the table and apply them as a team rather than carry around their individual backgrounds and try to preserve them. It's a pretty good environment here.

INTERVIEWER: It sounds like a synergy thing.

COMMANDER RODGERS: I would say that that's a good word.

INTERVIEWER: Are there any questions I haven't asked you, sir, or any topic we missed that comes to mind?

COMMANDER RODGERS: No, I don't think so.

INTERVIEWER: All right, sir. Thanks a lot.

COMMANDER RODGERS: You're welcome.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

ORAL HISTORY INTERVIEW: ARTHUR J. BACHRACH, PH.D.

Taos, New Mexico

Monday, September 22, 2003

## **PROCEEDINGS**

INTERVIEWER: It's September 22, 2003. I'm in the lovely adobe home of Dr. Art Bachrach and his interview will touch on a lot of the pieces of history that we do not have elsewhere. Art, let's get started and let's start at the beginning with where you were born, where you grew up, and where you went to school, even as far back as elementary school. We'll bring it all out and let's see what we can learn.

DR. BACHRACH: Well, I was born in New York, in New York City, and went to public schools in New York. I went to Columbia University, but the professor I wanted to work with moved over to City College, so I went there. I was 16 when I graduated from high school. I didn't really know what I wanted to do.

INTERVIEWER: That was young for high school. Tell us how you got through high school so quickly.

DR. BACHRACH: I skipped a couple of grades. In fact, I picked up one or two years in elementary school, so I got out early. It was 1939 and I went and got a job way downtown in New York City. I lived at the tip end of Manhattan, up near the area that what they called Spuyten Duyvil, or 'spitting devil,' in the Inwood area. It was country, or the suburbs, at that time. It isn't any more. I worked at an advertising agency as a runner and finally wound up in the art department. I started going to college at night, which was not easy. But I started taking psychology, was fascinated by psychology, so I quit my job and went to college full-time.

I was in the enlisted Reserve and got called up to the Army. We were supposed to be in some Air Corps program in Tennessee, a group of us who were psychology majors, but when we got off the troop train we wound up at Ft. McClellan, Alabama. Naïve as we were, we said there was a terrible mistake made, but we went through infantry basic training. I'd had the equivalent

of four years of college French, so somebody classified me as a French interpreter and I would have been in very difficult straits had I needed to perform as such. But that got me into the ASTP, the Army Specialized Training Program, so I was assigned to Amherst College to the language program, and we wound up in the Italian training program.

INTERVIEWER: Was that before or after World War II began?

DR. BACHRACH: It was after World War II began. I went into the Army in 1943 and was twenty years old at the time. To get into the program, you had to have a very high AGCT, the Army intelligence test, fluency in one language, and the equivalent of a college degree. The colonel who greeted us said, "You men are the cream of the United States Army." I looked around at the cream. I think I was a PFC at the time. There were sergeants and corporals and PFCs. I thought, "Well, Tom Lehrer," the Harvard University mathematician who was very funny, "once said that the Army never discriminated on the basis of race, creed, color, religion or ability." I looked at the cream of the crop, and the highest was a sergeant.

We went through the Italian training program which was an immersion program. We weren't permitted to speak English at any time in the barracks or the village or whatever, and in five months, we were fluent. Then, I spent two and one half years with the cobelligerenti program. We had 20,000 Italian prisoners in this camp who were being trained to take service jobs to free American soldiers for combat duty. Around the time of the Battle of the Bulge they cancelled the ASTP. They cancelled the Air Cadet Program and the 78th Division became almost entirely Air Cadets and ASTP. I went off into ordnance and then, finally, off again into infantry at Fort Benning, as an instructor.

INTERVIEWER: In what were you an instructor?

DR. BACHRACH: I was an instructor in rifles and marksmanship. I wasn't really that good but I could tell them what to do.

INTERVIEWER: What happened to the psychology track that you first started on?

DR. BACHRACH: Nothing happened. It was the typical Army, so absolutely nothing happened. But what did happen was that I wound up with the G.I. Bill of Rights so that when I got out of the Army, I went to Western Reserve University and got my master's degree. At the time, I couldn't take Cleveland's weather. Jones & Laughlin Steel Mill was operating and everybody had 'Cleveland Throat.' They've cleaned it up and it's really quite lovely now, though someone once said that Detroit is Cleveland without all the glitter. I got my master's and decided just to go to the University of Virginia and get my Ph.D. I had some friends in Virginia. I went there and had a job running the Behavioral Sciences Division in The Department of Neurology and Psychiatry at the University of Virginia. In 1952, I got my Ph.D.

INTERVIEWER: You were appointed to the position before you got your Ph.D.?

DR. BACHRACH: Yes, it was before I got my Ph.D. and when I got my Ph.D., I stayed on. I got my Ph.D. in 1952 and left in 1962. I was offered the job of professor and chairman of the Psychology Department at Arizona State University and it looked like an opportunity to build a whole new department. We had a good time. It was a very experimentally and physiologically oriented program. We applied for a THEMIS grant and our Program Manager was Jim Miller, who was head of the National Oceanic and Atmospheric Administration (NOAA) Diving Program. He was involved in Techite. Our research was in a hyperbaric chamber

INTERVIEWER: It was an undersea program?

DR. BACHRACH: It was an undersea program that Jim Miller was heading. We put a THEMIS grant in. THEMIS was the idea that Lyndon Johnson had to give money to universities that did

not have defense contracts so they could support education. THEMIS was the Greek goddess of justice and equality. Of course, most of the contracts seemed to go to Texas for some reason or another. But we got one at Arizona State and it was embarrassing to the university that we had a contract to do undersea research. We had a hyperbaric chamber.

INTERVIEWER: What brought the hyperbaric chamber to the university?

DR. BACHRACH: A program on which we worked for the Office of Naval Research (ONR). Under THEMIS, we had a diving project.

INTERVIEWER: That was purchased under the THEMIS program?

DR. BACHRACH: It was purchased under the THEMIS program. We tried to put in a Sea Grant proposal and found out that you didn't have to be on the coast to have a Sea Grant. But the president of the university said he'd be the laughing stock of the western universities if we had a Sea Grant program in the middle of the desert. Well, Jim Miller had to explain a lot, too, as to why we had an undersea program in Tempe, Arizona.

I'd had a contract in Virginia with the Office of Naval Research. They called me one day and said, "Would you run over to San Diego and look at the SeaLab program?" I said, "Well, I don't know anything about the underwater world." They said, "You don't have to. Just go over and see if the experimental design is going to yield data." I spent the summer of 1968 on SeaLab III and became absolutely hooked on the people and the project. At the end of the summer, the Navy offered me a job to set up a whole new biomedical program in diving at the Naval Medical Research Institute (NMRI). I left the university and went to the NMRI. That was in 1969.

INTERVIEWER: Would you explain how that came about, how that offer came about to you? You were out at SeaLab. Who was the officer in charge (OIC) then?

DR. BACHRACH: Mazzone was the Officer In Charge.

INTERVIEWER: Walt Mazzone.

DR. BACHRACH: I had known John Rasmussen and Paul Nelson. I had known Paul and Bob Nelson for years because I used to go to the American Psychological Association conventions and John Rasmussen was a graduate student at Northwestern University at the time. We became good friends and John was at BUMED, and so was Paul. They were working with NMRI in the behavioral sciences program and they, I believe, were the ones who instigated this business of asking if I'd be interested. I went back to Washington, D.C. and talked to Tor Richter, Paul, and John.

INTERVIEWER: Was Tor Richter the commanding officer then?

DR. BACHRACH: No, he was still at BUMED. But he was scheduled. He was slated to be the commanding officer. I decided that I would do it. It sounded like a good opportunity.

INTERVIEWER: Let's go back to your appointment at NMRI. I don't mean to interrupt you so much here, but you were offered a senior executive service appointment (SES). Isn't that right?

DR. BACHRACH: It was a Public Law 313 appointment.

INTERVIEWER: That's right. That was before the SES.

DR. BACHRACH: When Carter was President, he offered the PL-313s a chance to become senior executives, but it wasn't really much of an offer because you didn't have any other alternative. The PL-313 program was a very good program. It brought us senior scientists to a very good salary level.

INTERVIEWER: Not to mention the authority level it brought, as well. PL-313s were pretty high on the totem pole, so to speak.

DR. BACHRACH: Well, I wound up as an SES-4, which was high up on the totem pole. We had a lot of responsibility but not much authority. There are walls of Jell-O in government that you know as well as anybody.

INTERVIEWER: Yes. I know about those walls of Jell-O.

DR. BACHRACH: I remember that at one point, we were trying to appoint a physiologist in the department and Civilian Personnel at NMRI said, "Why don't you go down yourself to 23rd and E Streets, or whatever, to civilian personnel downtown, and present this. You'll get it through a lot faster." Well, I went down and there was this receptionist sitting, reading a magazine, and I finally got her attention. I found that being a SES-4 didn't do a lot, in terms of getting things accomplished, but it was nice. But I also had an equivalent rank of rear admiral and that got me into quarters. I remember Ken Sell went to a meeting. I think it was at Wright-Patterson AFB and I was put into admiral's quarters and he wasn't.

INTERVIEWER: He was your boss and you got better quarters.

DR. BACHRACH: That's right. He was my boss. At NMRI, when I arrived the program there was mostly isolation research for the National Aeronautics and Space Administration (NASA). It was social psychology and that was not what BUMED had in mind. They at least felt that the isolation work had contributed to the ideas of undersea habitats and space, but they were interested in different aspects of it.

We started working on hiring people and had people like Mike Walsh , who had been there for a number of years and just readily jumped in with ideas for research. Mike, as you may remember, became the person who did so much of the drug research, which was some excellent work. We had a good staff there. We had John Thomas. Then, I hired John Shroat. They were

psychologists who really were excellent. We had a number of really good people. But one of the first hires I made was an editor, Peg Matzen.

Every time I was in a position in which I was heading up a program, one of the first people I looked for was an editor, because the product of any scientific department are lectures, presentations at scientific meetings or papers and books. There was a lot of resistance to having an editor come aboard, but once they found out what somebody like Peg could do to make their prose sing and really clarify it, [they thought she was great]. My rationale was that they were doing a product. Writing was your product and you needed an editor. If you have a computer program, you don't mind getting a computer expert in to fix it if it breaks. It worked out very well.

INTERVIEWER: But you also taught scientific writing there, did you not?

DR. BACHRACH: Yes. That actually came about at Arizona State, when I was the chairman there and a graduate student came in with a shy look and asked, "Would you help me? I need to write a curriculum vitae." My first response was, "What do you mean? Everybody knows how to write a curriculum vitae." Then, I thought, "Not necessarily." We started a volunteer program that met once a week on what we called 'Professional Issues' and it was completely voluntary. You could bring a sack lunch. One week we'd talk about how to go for a job interview. How do you present yourself? We suggested other things, like going out and having a beer with the graduate students and seeing what they thought about the department that you were looking to join. We talked about professional issues, like retirement benefits, insurance, what your teaching load was going to be, and what kind of a lab you were going to have.

The professional issues developed. People kept saying, "Well, I'm having trouble writing my research." I put up a course in scientific writing. It was a regular 16-week course. Then, I

took the idea to NMRI and taught scientific writing and editing to the editors and also for scientists, and it went over very well. I think people really seemed to like it. Peg Matzen was a big help in that, of course, as an editor. But I still feel that scientific writing is something in which scientists really need some help.

INTERVIEWER: I think you proved that at NMRI. They were good scientists but their writing was not always as it ought to be.

DR. BACHRACH: No. Their writing was not always the best. Maggie Meitzler was also one of the people who helped me. She's now an editor with the Oxford University Press and an editor for the National Cancer Institute. She was a NMRI editor and very helpful in working with us.

INTERVIEWER: I want to take this back to the isolation studies and see if you can verify a story that Gerald Duffner told. By the way, were you there while he was at NMRI?

DR. BACHRACH: No. I was there after Gerald Duffner.

INTERVIEWER: It was after Gerald Duffner. You may not remember this.

DR. BACHRACH: Sudduth was the commanding officer when I got there.

INTERVIEWER: You may have heard this story. It was during some isolation studies when they locked a group of people in the tunnel that ran from the officers' quarters to the hospital at the National Naval Medical Center in Bethesda, Maryland. They just locked both doors and kept them in there.

Well, that attracted a lot of attention and the television cameras were there, interviewing people and so forth. Gerald Duffner was the guy who was heading that particular isolation study. When they were about ready to open the doors and let the subjects out, a television newsperson asked him, during a live interview, "What was the one thing that could not be met in providing all the needs of the people who were isolated?" Duffner said that he couldn't think of anything.

His mind was blank, except that one of the subjects had an insatiable appetite for cottage cheese and they couldn't get him any because of the restrictive diet they were on. The next morning, there were trucks lined up in front of NMRI with cottage cheese to give all the guys as much cottage cheese as they wanted. Did you ever hear that story?

DR. BACHRACH: I never heard that story.

INTERVIEWER: Well, I wish you could have validated it because it has always been an interesting story to me, about something that happened in the early isolation studies. But I thought it was so funny.

DR. BACHRACH: Bill Hayward was the department chairman when that research was going on. He could validate it. I don't know where he is. He was in Germany, years ago, working for the Army.

INTERVIEWER: Go back to those isolation studies and bring it on from there. Tell me about your involvement.

DR. BACHRACH: Well, we were phasing out the isolation studies. It was in a contract with NASA and there were some realistic aspects of isolation. One of the things that I think we learned from the isolation studies was seen on SeaLab III. When you get into a limited stimulus situation, say, the fourteenth cough behind you in the movies is no louder than the first cough, but by the time the fourteenth cough comes, you're sitting there with your shoulders tensed. That is stimulus intensity in a low stimulus area. You get high in stimulus intensity from limited space. I'm sure it was also true on SeaLabs I and II.

We did see in isolation studies, and this has been reported generally, that there were mannerisms that would really get on people's nerves, like the way people ate or things like that, or repetitive phrases. People would keep using the same phrase. I don't entirely believe in

stimulation because they can get out and they *know* they can get out, but you still get some reality in there.

I remember talking to the divers in SeaLab II. Some of them didn't get along on the surface at all. But the phrase I heard several times from people, about when they were isolated in the habitat, down on the bottom, was that they were 'walking on eggs.' They were very careful not to do anything to annoy each other, although Bob Barth did bring chili down to the SeaLab and that was killed in a flash.

The isolation studies, I think, taught us something about what happens in a low stimulus situation. But I don't think that they, in my own opinion, contributed too much to the reality of the situation because of that one factor. They could get out. We're getting into sea stories, but there was a time they were doing a thousand-foot dive at the Experimental Diving Unit (EDU) in Washington, D.C., down at Anacostia. One diver's wife was allowed in to talk to him on the radio. The chief never should have let her in, but he did, and she announced over the phone that she was leaving him. Of course, he went berserk and they had to sedate him and keep him down, but what a wonderful "Dear John" letter that was. She knew that he couldn't get at her.

One important result of working with NASA was technology transfer. There was a researcher by the name of Chuck Kubokawa at AMES/NASA with whom we worked, and he gave us some thermal suits from the space program. We tried them out for divers and found them useful, a good transfer. Of course, NASA, the Navy and the military in general, I think, have contributed a great deal to what we know now as medical technology and scientific technology.

INTERVIEWER: At what point did the isolation studies evolve into all of the diving studies that you did there and all of the work that you did with divers? Now, I can see how that transfer

happened that you mentioned just a moment ago, but I think there was more involved than that, right?

DR. BACHRACH: Well, yes. There was some very good research in the isolation studies, but BUMED thought that we had gotten as much out of the studies as we could. They wanted to get into some of the aspects of diving and particularly, the performance and physiological costs. We phased out isolation and some staff left. Mike Walsh just took his experimental skills and applied them to the diving research. We started getting into diving research and one of the first areas that we got into was high-pressure nervous syndrome (HPNS).

We also had a memorandum of understanding (MOU) with the Royal Navy (RN). Peter Bennett was still in England at the Royal Naval Physiological Laboratory in Alverstoke. We had a MOU where the U.S. panel would meet with the RN panel. We had this project going on HPNS. We had a very fine instrumentation group with George Trensanski. His group built an intentional tremor device similar to one we built while I was doing some tremor research at Arizona State. We had a middle European machinist named Lazlo, who was a marvelous machinist and used to put jewelers rings on everything. I said to him one day, "This is going to be in a case. No one is ever going to see it." He said, "I'll know it's there." It was like the ship model builders of the 16th century on up who closed the hull. But if you look through fiber optics in Annapolis, as they did some years ago, inside a lot of the ship models they found fully carved figures, cannons, bunks, and everything. Well, Lazlo was like that. He would do jewelers rings. We had a model for a tremor device and the machinists and technicians at NMRI built an excellent one. That was some of our first research into diving. That was in cooperation with the RN.

INTERVIEWER: Explain just a bit about high-pressure nervous syndrome and what it does to divers.

DR. BACHRACH: With high-pressure nervous syndrome, generally, the first symptom is tremor. That was why we were interested in measuring tremors. It was so that we could see if we could pick it up early. Well, it could get as far as seizures, but it's generally a matter of imbalance and neurological symptoms that interfere with perception and work. It's usually a factor of depth and compression. Slow compression seems to be a lot healthier.

INTERVIEWER: Does it have the potential of endangering the person's life?

DR. BACHRACH: Oh, yes, indeed. I think that was what happened when we started getting into deep diving. At one time, people were talking about 2,000 to 3,000-foot limits. Well, I believe it was proven on the Lambertsen-University of Pennsylvania dives in the 75s and in Bennett's dives at Duke University. At depth, there were signs of HPNS, like tremor. It could be endangering. We still don't know the long-range effects of high-pressure nervous syndrome.

INTERVIEWER: Some have said helium plays a part in HPNS. Did you ever find that to be true? You said that it has more to do with the pressure and depth.

DR. BACHRACH: Well, I'd like to see the term 'inert' banished from the English language. Inert gas is not necessarily biologically inert and we did some studies with helium. I think Steve Gruneau was the one who did these studies at NMRI and recorded EEGs and found that there were definite changes on helium at depth.

'Inert' is not a biologically sound term and I think it has come true that human exposure to depth is not needed. Now, the human diver has been replaced with ROV's and submersibles, and submersibles have become more fuel efficient, so they are much more usable. But I see no point in exposing a human diver to the pressures of a really deep depth.

For example, when inspecting pipelines now, they don't use divers that much. They just run an ROV over the surface and sit up with bourbon in their hands and watch the screen and see what happens. This idea, actually, plus the HPNS and the exposure to physiological pressure and damage led me to think that there has got to be an alternative to deep diving. In 1975, I was in London at Oceans 2000 and saw JIM, the one atmosphere diving suit, for the first time. A little light went on in the attic and you could hear the steps coming down the stairs saying, "this might be an alternative."

It took me two years to convince the Navy to lease JIM from the British. Finally, we got permission to put the research proposal in to do a study of the one atmosphere diving system. There had been some tests on it before. The EDU tested it and they said that it was not mobile. Well, it turned out that they had him tethered in the pool. You didn't tether JIM. There was a line going to the surface, but that was primarily for getting him up and down and for communication. The one atmosphere diving system was, by definition, self-sufficient and self-contained. In 1977, we got JIM-4 and did a biomedical assessment of JIM and other research that was being studied up at New London. We did a very intensive study of JIM, as you know, over two years of research. We felt that one of the things we needed to do was a fleet-relevant study. We went down to Pax River and simulated one. JIM went down and released a pilot from the seat of a downed aircraft to bring up the body. We also tried to find the flight recorder with JIM.

In the report I did on JIM, I confess I stacked the decks. I had two columns. Suppose you had an accident at a thousand feet. It would take you ten minutes to get JIM to the bottom. We also did a fleet-relevant study in which we had the operator taking pictures through the glass window. You could document an accident using JIM and bring him up in ten minutes. If you

really wanted to do a trout fly fishing thing, you could bring him up in five minutes, but he might come up a little fast. But you could get him up with no decompression from a thousand feet.

On the other side, and I was again stacking the deck a little bit, I considered what would happen if you compressed a diver to a thousand feet and then brought him up. Well, he'd spend ten days in decompression. We thought that JIM had a lot of fleet relevance. It took 25 years before the fleet really started using JIM. At the symposium in 2001, they were reporting on the successful use of a one atmosphere diving system.

INTERVIEWER: Yes, they finally bought a couple.

DR. BACHRACH: Well, Ed Coil, Jim Vorosmarti and I went to the Pentagon because they were talking about starting a program for NOMADS, the Naval One Man Atmosphere Diving System, and we asked, "Well, why do you want to start all over again? JIM has been proven and there have been thousands of dives with him. Why don't you buy one, paint it blue and gold, but don't start all over again?"

Ed Coil was very supportive, as was Vorosmarti. He was the commanding officer at the time. I believe those were the happiest research years of my life. Working with divers is so rewarding in so many ways. On SeaLab III I became very close friends with Ken Conda and one of the first things I did when Ken got out of the Navy was to hire him at NMRI. I also hired Bill Armstrong. I got two SeaLab divers, as civilians, and my belief was that you couldn't train a scientist to be a diver very well but you might be able to train a diver to do research. We had Ken Conda on the bottom at Aegir, in Hawaii, and you couldn't fool him because he knew when a diver was fooling around. He was an excellent researcher.

INTERVIEWER: I'll never forget Ken Conda for the fact that he couldn't swim worth a lick on the surface. But he was one of the hardest working divers I've ever been with in the water. Ken is

quite a fellow. Speaking of people, that reminds me. In diving, your studies put you in touch with an awful lot of people. Pick out some of those people and talk about them, those who really stick out in your memory. You mentioned Ken Conda, of course, but there are others. There are scientists and people in the line, for example, in the Navy and people in universities and so forth.

DR. BACHRACH: Ken Conda and I got to be very, very close friends and on SeaLab III, I was put through a gauntlet. Here I was, a psychologist aboard SeaLab. For the first two weeks, they took me down to the Blue Fox in Tijuana. They took me to the Body Shop in San Diego and ran me through this test.

At the end of two weeks, Bob Barth said to me, "Well, you're okay for a ding-a-ling." I got to really respect and know the divers. Bob Barth is truly one of the people who has always stuck out in my mind as a leader, an individual who could do anything, and was a fine, respected person. I felt that George Bond was an incredible father figure, almost. 'Papa Topside.' George was maybe not the greatest scientist because we do know, and I was in on some of this, that he would interrupt some of the research on the bottom, at times, to give a sermon. He was religious and loved to quote scripture. In the middle of an experiment, his voice would come down and he would read to them. But George Bond was one of the people I really respected.

Scott Carpenter was another. I was at a Monday morning staff meeting in SeaLab and Scott proposed a checklist, which was very compulsive and very detailed. It came out of his space experience. We had the tragic death of Berry Cannon and they found out that the carbon dioxide canister was empty, the scrubber. That's the background on Scott's checklist, which was never adopted.

INTERVIEWER: It was never adopted, you said?

DR. BACHRACH: No. I also had the opportunity to meet Phillipe Cousteau. Phillipe was on SeaLab III and Navy divers were not very happy, because his being on SeaLab III meant that one Navy diver would not be assigned to SeaLab III. As you know, there were no rewards, in terms of promotions or special kinds of medals or anything, from SeaLab III. But they knew that every diver in the world knew they were down on SeaLab III and it was a very important thing for the Navy divers. Phillipe got one of the assignments.

They were grumbling about PR but within a week, he had worked so hard and was such a good diver and great guy that he was completely accepted and he was a very important figure. I was very lucky. I happened to be at the right spot at the right time. We had projects at NMRI with the RN in England and with Sweden, Japan, and France. I had the chance to meet people in England, people like David Elliott, who was an exchange officer. David, to me, was one of the great scientists and one of the finest people I have ever known.

I also met John Rawlins, who was at NMRI. I got to know John pretty well and we still keep in touch. I go over to the Historical Diving Society in England every year. I'm going next month to Portsmouth. Vorosmarti and I go together. He's a good traveling companion because we have the same priorities: museums, pubs, and naps, but not necessarily in that order.

In England, I also met people like Peter Barnard , who was excellent. He was very quiet but a superb researcher and a fine physician. He and David Elliott stand out as the people at Alverstoke. The group at DHL where JIM was developed and the people in Farnborough. Mike Borrow, who was one of the early people working on the JIM project, was an excellent person.

In Sweden, there were people like John Adolfsen , who came for a year in NMRI as a visiting scientist. He did some pretty basic work, some classic work, on performance measures. There was also the whole Japanese group. Kawashima and Mano were really fine people. Mano

and Kawashima were the two who translated the book that Glen Egstrom and I wrote on stress and performance in diving. They translated it into Japanese, which was very flattering. Of course, I don't know if they did a good job because I can't read it.

I was fortunate. I happened to be in England when they were working on the [HMS] *Mary Rose*. I would go over at Portsmouth to the conservatory to see what they were doing. It was the same thing with the Swedish ship *Wasa*. When I was in Stockholm, on at least three occasions I got on board the *Wasa* with a 'souwester' to protect us from the polyethylene glycol spray. I read in *Science* magazine just this week that they're having trouble because they're getting oxidation and sulfuric acid in the *Wasa* and it's in serious trouble.

INTERVIEWER: They have it housed now, don't they?

DR. BACHRACH: I'm not sure. The *Mary Rose* is under glass. I don't know whether they house the *Wasa*. But there were opportunities, like with the French in Toulon. There were pretty good people there, like at Aix-en-Provence, Maurice Hugon, who was head of the department, and Guy Imbert, who came up to NMRI for a while.

INTERVIEWER: How about Broussole? Did you know him?

DR. BACHRACH: Yes.

INTERVIEWER: Was he General Broussole?

DR. BACHRACH: He was Admiral Broussole. He organized a symposium in Toulon in 1977. They were just beginning to get over the Gaullist influence and were able to speak English to us. For a while there, when you were working with the French, they were not permitted to lecture or report in any other language but French. That DeGaulle influence eased.

In my own department, people like John Thomas, John Shroat and Mike Walsh were really just great people to work with. We had an opportunity to interact with so many different

laboratories all over the world, like those in Stockholm and Copenhagen, and I was very fortunate that I had these opportunities to meet these people. The people who stand out are people like Scott Carpenter, with whom I still keep in touch.

INTERVIEWER: Speaking of Scott Carpenter, in your opinion, if SeaLab had adopted Scott's checklist, do you think that might have prevented Berry Cannon's death?

DR. BACHRACH: Yes, although we never found out what actually killed Berry Cannon. There are several theories. Someone said that there were handprints on the habitat. They think that maybe he was electrocuted. The inquiry never gave out the report but it was definitely true that the carbon dioxide scrubber was empty.

I got along very, very well with the divers whom I liked and respected. Paul Linaweaver was the medical officer. I went back to Tempe after Berry Cannon's death. The depression that set in on everybody, who were just standing around, dazed, was just unbelievable and horrifying.

As an aside, I mentioned to Scott...I asked him why this incident killed the undersea program, but Gus Grissom's crew's death didn't kill the space program. Scott gave an answer that I think is probably valid. He said that the space program was a national program and the undersea program was not. There was national interest in the space program, but you could never engender that much interest for the undersea program. I think that may have contributed to it. But let's go back to Paul Linaweaver. He called me and asked, "Would you come back over to San Diego and talk to P.G. Wells? He's going to resign from the Navy because he feels culpable in Cannon's death. He said, 'I should have checked the equipment better.'" P.G. and I got along very well, so I flew over to San Diego and we had a very long, long session and he kept saying, "Well, it was my fault and I can't really handle being in the Navy anymore because I think I failed." There was no way that I could convince him that he should stay. He not only resigned,

but also, every time they have had a SeaLab reunion, and he still lives in Panama City, they've sent him notice and he never shows up. I think that is one of the real tragedies of SeaLab III. Berry's death was tragic. I think the Navy's loss of Wells, and his own feelings, were other really tragic consequences.

INTERVIEWER: As tragic as it was, some have hailed SeaLab III as being tremendously successful in many ways. Do you agree with that opinion?

DR. BACHRACH: Yes, I do.

INTERVIEWER: Can you list some of those successes? What came out of it?

DR. BACHRACH: I think the whole SeaLab program, I, II, and III, demonstrated that first of all, saturation diving was a practical, useful tool and commercial diving picked up saturation diving early and it was a useful tool for their purposes. When they tried to get the stuff from the *Andrea Doria*, they never could until they put a habitat down there. It was the same thing with the *Lusitania*. I was onboard the *Lusitania* for a while in 1968. There was only a one month window in June in which you could actually work, because they had 11-foot swells off Kinsale, which is the town, the old Head of Kinsale...eleven miles off Kinsale was where the *Lusitania* sank. Years later the ship was reached by habitat, again proving that saturation diving had a function.

We look back and think of the TWA 800 crash. We could have had saturation diving capability instead of having 150 divers going down and getting bent because, as I was told, they were being pushed to dive more because the press was standing there with their little cameras. Saturation diving also demonstrated, more than the isolation studies that have been done at the National Institute of Health and NMRI, that you could get people in isolation to work together and work effectively. Saturation diving had implications for space, as well the SeaLab habitat programs. We learned a lot about different kinds of equipment and about the gases. We also

learned that you could use a single compression and decompression function with a personnel transfer capsule to get work done. That became one of the main techniques in the North Sea, having diving bells with which you could lock out divers.

I believe the SeaLab programs, along with Ed Link and Cousteau and some of the other saturation divers were very important. I remember that Cousteau complained one time when they were down in ConShelf at 35 feet, or something like that. They had a real serious problem. The champagne had gone flat.

One of my friends was, as I recall, in the National Academy of Sciences with the marine division. Once a year, they had to do a report on what they had done with marine research. The Vice President of the United States always wrote the Foreward. Rather, someone wrote it for him and he signed it. I can't remember his name, but I had a friend who worked there and he told me one time that Hubert Humphrey, when he was Vice President, would come down to see them at least once a month. He'd sit there and say, "what can we get from the sea. Can we get food? Can we get drugs? What can we get from maritime research?" They said that they'd never had a Vice President who did that, and they believed that if Humphrey had been elected President, the ocean program would have been supported a lot more than it had been, because of his own interest. It's a little aside and a political thing, but he had a strong interest in what the sea could do for the world, not exploiting it as much as using it for humanitarian and commercial purposes.

INTERVIEWER: I didn't know that about Hubert Humphrey. That's interesting. You were also a qualified diver. You did some SCUBA diving?

DR. BACHRACH: Yes.

INTERVIEWER: Would you explain your first experience underwater and the SCUBA diving that you did?

DR. BACHRACH: Well, I got certified in 1967 and my checkout dives were down in Mexico. My first experience underwater was a combination of anxiety and awe, in that I felt graceful. I'm not very graceful on land, but underwater I felt graceful and the beauty was almost overwhelming. But there was also an anxiety, an apprehension, and I finally got over the apprehension and felt more comfortable with the equipment and the opportunity to get under and see things. When I was in good shape I could go down forty feet, snorkeling. At fifty feet, the color is going to change, anyway. I just had opportunities in some of the dive medicine courses I used to lecture at, to go on dives in the Caribbean and Bonaire and Hawaii. It was good.

I also had a better feeling for what problems could arise and I remember one hazing they did while I was in training. It was to sneak up and take off your mask. It was dumb, but it was an opportunity to teach you that you didn't really need the mask. It was nice to have. I got interested in what the mask meant to people and that got me interested in diver panic. I did a lot of studies about diver panic. Glen Egstrom, of UCLA, and I did the first paper on diver panic in the 1970s, in *Skin Diver* magazine. Even though people had been talking about panic, no one ever sat down and wrote up what to look for and how possibly to avert it.

The masks in anesthesia are very symbolic problems. In dive training it was one of the ways you screened people, as to whether they were going to make divers, because the mask can be a very significant feature of discomfort and ultimate panic. I found out that there were lots of studies that had been done on the mask. We did a study at NMRI that we never published because we didn't get enough data. But we had divers, sitting in a warm room, have them put the mask on and we had EEGs on each subject. We found out that just putting the mask on touched the trigeminal, and the trigeminal is linked up to the vagus and we could get a little bradycardia in a warm room, just by putting the mask on. We never really finished that study. We had some

pretty interesting results there. My SCUBA diving career was fun but it was also an opportunity to get a feeling for what divers were going through, not that I ever got into deep diving.

INTERVIEWER: You mentioned earlier that you did some things with Glen Egstrom from the University of California-Los Angeles (UCLA). Tell us something about that, about how you two got to know each other and what you did together.

DR. BACHRACH: Well, in 1968, the Office of Naval Research called a meeting of people who had been involved in doing research underwater. In 1968 it was in Arlington and Glen made a presentation, and I made a presentation. We were walking out of the room together and looked at each other and said, "You really made sense." or something to that effect. Then, we went out for a drink and then was when we really started our friendship and we've kept it up ever since. We've done a lot of papers together. We did the book together, *Stress and Performance in Diving*, and we still keep in touch. He is a fine friend.

Fred Bove called last year and asked if we'd do the human performance underwater chapter again for his diving medicine book. Well, Glen is retired and I am retired. We said to Fred, "Isn't there anybody out there who is actually *doing* the research?" He said, "Not really. You guys still keep up with what's happening." We said, "Sure." But it's ironic. I think Glen retired in 1990, and I retired in 1987, and we are` still asked to do a chapter like that. I think there is something lacking out in the field somehow.

INTERVIEWER: Yes, there is. He was a professor of kinesiology. Isn't that right?

DR. BACHRACH: Yes, he was a professor at UCLA.

INTERVIEWER: You mentioned earlier about going to the Historical Diving Society meeting. You're very well known in the field as being an expert on the history of diving. How did that all come about?

DR. BACHRACH: Well, I've often thought that there are three periods in a scientist's life. In the first period, he is at the bench doing experimental science. Then, as he gets on in years, he becomes a reviewer of other people's work, reviewing for journals or grants, proposals, and so on. In the third period, I think, he could get interested in the field and just how it came about.

I started getting really interested in the history of diving because they talked about it. Here, I've got the paperweight from the British celebration of fifty years of diving. Well, I gave a paper at one of the dive meetings, at Our World Underwater in Chicago, which was something like 216 years of diving because I found that in 1719, a Frenchman named Mandeville had invented a SCUBA, which didn't entirely work, but the concept was there. The concept has been around since the 1600s.

I just got very interested in it and I went to meetings of the Historical Diving Society in England with Reg Vallintine, John Bevan, and Nick Baker and people like that. Peter Dick, who is now the editor of the *Historical Diving Times* for the British, was another. These people were just really unbelievably knowledgeable in diving. John Bevan has his book on the Deane's, *The Infernal Diver*, John Deane. There was also Daniel David, a French historian who spent a lot of time in patent offices, and he came up with inventions and superb information..

In the first book, *Naval Forces Under the Sea*, there is an illustration of a diving system from 1828 that D' Augerville, who was a French dentist, invented and it was adopted by the French navy. The whole idea that SCUBA diving started with Cousteau in 1946 is just wrong because there is a history. In 1865, Rouquayrol and Denayrouze patented what was essentially one of the earliest, if not the first, demand regulators.

I just got interested in where all of this came from and corresponded with people like Daniel David, Bevan and Reg Vallintine and became more and more interested. I started doing

some research. I was in France at the Archives Nationales and I found an 1826 engraving of a diver with a leather bellows on his head, which would fill with air as he was working under the Pont Neuf on the hydraulic system. There is an engraving from 1826 of this diver with an air reserve. It is in my history of diving section in the 2001 symposium.

I became interested in the history of the diving bell, which I published. I got really interested in from the bucket onward. A helmet is essentially an individual's diving bell. So, there was all this development through the years in France and Britain, in particular. All of a sudden, I became more knowledgeable.

INTERVIEWER: Well, I think you certainly became one of the world's experts on the history of diving.

DR. BACHRACH: Oh, I wouldn't say that. Far from it! I look at John Bevan, Reg Vallintine, and Peter Dick from the UK and Daniel David of France as the true experts.

INTERVIEWER: I'd say that because what you bring out in your lectures on the history of diving is marvelous.

DR. BACHRACH: Well, I thought that in *Naval Forces Under the Sea*, the graphics people did an incredible job in organizing it because it was a hodge-podge of slides and they did a beautiful job just leading you through it.

INTERVIEWER: Actually, Lou Nuckols did most of that.

DR. BACHRACH: Did he?

INTERVIEWER: Yes. He had some help, I suppose, because he had access to all of the graphics and video people, but he placed most of the graphics.

DR. BACHRACH: That's great.

INTERVIEWER: He did a great job. This next question is a rather lengthy one, so I'll read it all and see where we go with it. Ocean floor habitat diving was moving along at a remarkable pace during the early part of the last half of the twentieth century, until we lost Berry Cannon during the operation of Navy SeaLab III, which we talked about just a moment ago. From then onward, habitat diving lost its luster. What is your opinion as to why? Was it Berry Cannon's unfortunate death or something else? Also, if Berry Cannon had not died, what is your opinion as to what the Navy would have developed from the SeaLab III experiments?

DR. BACHRACH: Well, I think I mentioned before, that Scott Carpenter said that space had this national interest and the ocean did not. I think that Berry's death was probably the reason for canceling the program, but I believe that the Navy deep submergence people had probably gotten as much as they wanted out of the habitats in the three experiments.

I think that it was hard to find a military application for habitats. That was part of it. Would you need a habitat, for example, to lay SOSUS lines? You would probably not. What would it be used for, in terms of things other than rescues? I still think that saturation diving for the TWA 800 could have done it.

In fact, it could have been used with the USS *Squalus*, if we had had saturation diving with *Squalus* instead of doing over 600 and some odd dives with a ten minute time because of decompression. It took over a month to do *Squalus*. With a saturation habitat, had there been one, like on the TWA crash, you could have done it a lot faster and more safely.

INTERVIEWER: In that case, though, there would have been a surface chamber with a PTC, correct? Is that what you're thinking of, rather than an ocean floor habitat, or is your opinion that it wouldn't matter?

DR. BACHRACH: Well, I don't think it would matter because the Aegir in Hawaii, which was Tap Pryor's concept, where we did some Navy research, was an excellent concept. The Aegir was a compression chamber. They compressed on the surface dockside, lowered the habitat to the bottom, and it became a habitat. They locked out at 540 feet, did the work, and then brought it to the surface and decompressed in the habitat. The habitat became a personnel transfer capsule and a decompression chamber and a workstation all in one unit. I thought that was an excellent concept.

INTERVIEWER: I agree with that. It was an excellent concept. That was after SeaLab III and yet the Navy determined they would not do any more habitat dives.

DR. BACHRACH: Well, they were Navy dives.

INTERVIEWER: Do you think it was because they looked upon what they needed and the mission was complete?

DR. BACHRACH: Yes, I believe that's the case. I think Berry Cannon's death was just one other reason to say, "Well, we don't need the program any more."

INTERVIEWER: The DSRVs, the Deep Submergence Rescue Vessels, are going out of service and are being replaced by other types of submarine rescue systems. What's your opinion as to the utility of the DSRVs, during their lifetimes, and what is your opinion about new submarine rescue systems like the Submarine Rescue and Diving Recompression System that is soon to be launched?

DR. BACHRACH: Well, I think the DSRVs have a mixed history. There was not great success with them. I believe the concept is still an important one because submarine rescue is still a very emotional factor in the service. There is drama and pathos and all sorts of emotions with a stranded submarine, but the DSRVs were never that successful. This is not an area I feel I have

any authority in, but I think that my understanding of what the new systems will be is that they are a lot more practical and the application of these systems probably will bring more success than the early DSRVs did. But, as I said, I'm not really expert in this area, but I know that there were always, it seemed to me, some problem with the DSRVs.

INTERVIEWER: Yes, well, the one that's still operating still has its problems. But I'm curious, too, if maybe anything in your studies you might have done, or that Glen Egstrom might have done, had an impact on how they designed the DSRV. Do you know of any studies that were used for that in kinesiology, for example?

DR. BACHRACH: No.

INTERVIEWER: Who did the human performance on that?

DR. BACHRACH: They never did do that. Of course, human factors were never a high priority in the service. I remember, before I went to work at NMRI, that I was invited to go to Woods Hole for an ASR conference. I said I didn't know anything about ASR. They said that they wanted to bring about ten people who had no experience at all, in the field of anti-submarine warfare, to bring a fresh voice and a fresh look at the problem.

Well, it turned out that it took days to inform us of what the problems were. I can recount one of the things that I remember, and I think this is true also for other aspects of military application. You have a PB-3, basically an Electra airframe, Orion, and it was the anti-submarine plane. Engineers have never been terribly kind to people who use equipment. To get more time on the station, we were told, they took the head out of the plane and put a bucket in. The crew would boast about having ten-hour bladders because they didn't want to use the honey bucket, so they just held it. Well, I'm not sure what impact that would have on performance, but it was certainly a human factor aspect that was ignored. I don't think that was unusual.

ONR asked me to look at the habitat at SeaLab III and give them a human factors report, which I did. Bob Barth took me on a tour of the habitat and I looked at the microwave oven they had and it was right across from the head. I said to Bob Barth, "That seems to be poor placement because you've got the head right where you're preparing food." He said, "Yes, I guess it is. Well, Duncan-Hines isn't going to recommend us." But I'm being prolix here. I'm talking too long about this.

I think basically what I'm saying is that I don't think that human factors ever really were considered that critical, except when we were doing the MK-12 vs MK-5 evaluation. When we were tasked, as you remember, to do the MK-12, I wanted to also do the MK-5. I had to go downtown. It wasn't BUMED then, Research and Development. I went down and said, "You've got to do the MK-5. You've got to do the same studies." They asked, Why?" I said "Well, if you're going to replace the MK-5 with the MK-12, you should know whether it is superior and the only way you're going to find that out is to do the comparative tests." Glen Egstrom was involved in that and we did range of motion studies and physiological cost studies and we did what I thought was a pretty thorough study of the MK-12 and the MK-5. For example, in the MK-5, working overhead was more difficult because of the breastplate. Working overhead is the least successful aspect of any kind of work.

At the Bureau of Standards, I took an accident methodology course once. The instructor asked, "Where do you think the highest incidence of chain saw accidents are, on the human body?" We all said, "Legs." He said, "No, it is the neck and shoulders. That's because people will be sawing and it kicks back." We found that in the MK-5, they were less successful in application overhead than they were on the MK-12, because there was more freedom. The range

of motion, I think, was one study in which human engineering and human factors did have some impact.

INTERVIEWER: Well, it had to have had a great impact. I know that for a fact. It was the human factors study that convinced the powers that be in the Navy to bring that MK-12 system into existence and replace the MK-5. That was the overriding factor that caused them to decide to make that a system, and it stayed in service for twenty years.

DR. BACHRACH: No one ever told me that, but it's nice to hear.

INTERVIEWER: I can tell you for sure. That's what did it.

DR. BACHRACH: Well, we worked pretty hard on that. Mike Curley was very much involved in that. He was another person for whom I had a tremendous respect and still do. He's a marvelous scientist and a great person. Mike was very active with the human factor aspect of it. Yes, we were proud of that study. Of all the research I've done over the decades and decades, I think the two things I feel the most proud of are the JIM studies and the MK-12 studies.

INTERVIEWER: I think that answers my next question. I was going to ask you of all the things you've been involved with what brought you the most satisfaction, and it would be JIM and the MK-12?

DR. BACHRACH: It would be the JIM and the Mark 12.

INTERVIEWER: That's good. What would you say would be your most important contribution to diving and submarine rescue?

DR. BACHRACH: I don't think I've contributed anything to submarine rescue. For the Navy, I think my contribution was to get basic quantification, for want of a better word, of some of the activities and performance that Navy divers are doing.

Tom Berghage and I did a study once, and it was not well received. We found that the majority of Navy divers were diving at fifty feet, for less than a half-hour. We did that report and we found a high percentage of shallow diving. But there was not that much research in shallow diving and the budget was geared toward saturation diving, which was always a fraction of what the Navy was doing.

I think my contribution was to get some quantification of, well, just the range of motion studies, the heat stress studies, and the cold stress studies at NMRI, instead of getting subjective evaluations of equipment, like 'that one works better than this one.' What we were doing wasn't a diving project during the last couple years of my time in NMRI; we were studying the chemical defense suits for the Persian Gulf war. We ran them through all sorts of human factors and physiological costs in the heat and cold chambers, the treadmill and the full field pack. Then, we wet the suit and we found out that when you wet the suit, it no longer protected against chemical agents. I reported that at a meeting with the Air Force, Army, and Navy, all working on the chemical defense suits. The Army colonel in charge said, "What difference does that make. They're not going to get that wet." I said, "By definition, a Marine gets wet." I think my inquiring mind was probably what contributed to all of it because I kept thinking, "What is he actually going to *do*? How can we measure what's going to happen if he does?" That's simplistic. Task analysis is basic to equipment design and to operational use.

To submarine rescue I contributed nothing, but I like to believe I contributed to diving. My interest in diver panic was less applicable to the Navy than it was to the civilian community, but Glen and I really got into this whole business of diver panic. I feel that was a contribution, to start getting some analysis of accident methodology.

I subscribe to the school of accident methodology that argues an accident is an unforeseen event. It's not preventable. 'Accident prevention' is a meaningless term. You can get accident *mitigation*. If you have a hard hat you're not going prevent an accident. But it could mitigate the consequences. That was something that I kept pushing, for accident methodology. The aviation industry is much better at accident reporting than the diving industry. They report near misses and we never do, and I think you could learn more from near misses than you can from accidents. But an accident is something you're not going to prevent but you can prepare for in training. I think that was something I pushed hard and maybe had some impact.

INTERVIEWER: Tell me, is there a story or incident you've never told? If there is, can you tell it now? Now, that's getting a little personal, maybe, but I want to ask the question anyway.

DR. BACHRACH: Well, I'll tell you. A bunch of us on SeaLab were sitting in the Bali Hai in Shelter Island and we had one Navy grog after another.

INTERVIEWER: What would that be, a grog?

DR. BACHRACH: It was the rum drink at the Bali Hai. George Bond said, "Let's all go downtown and get 'SeaLab' tattooed on our arms. We said, "What a great idea." So, we went down to, I think it was First Avenue in San Diego, probably half a dozen of us. I can't even remember. We went down and the tattoo artist looked at the SeaLab patch that someone was wearing and said, "I don't think I could do justice to that, but there is a tattoo artist in San Francisco who could do a beautiful, beautiful job." George Bond asked, "What's his phone number?" and the tatoo artist gave George the phone number. By the time he got around to phoning, we all sobered up a little bit and we decided no, we didn't want a tattoo. If that tattoo artist in San Diego had been sufficiently confident in doing a good job I'd probably be walking

around with a Sea Lab tattoo. I don't think I've ever told that story but George could lead you anywhere. People would follow him. He was a remarkable person.

INTERVIEWER: He really was.

DR. BACHRACH: I told Barth this story. I was down for the dedication of the George Bond Saturation System in Panama City and afterward, a bunch of us went out to a bar and had some drinks. I was sitting next to this young diving officer and he said, "Sir, could I ask you a question?" and I said, "Sure." He looked around and he asked, "Who was George Bond?" I thought, "Oh my God," and I told him. I got hold of Barth and said, "You got to brief these guys." Some of them, or at least this one man, didn't know who George Bond was. I guess there was an assumption that well, everybody knows who George Bond was. But here was a diving medical officer, or maybe a diving officer, and he was embarrassed to ask. I guess he could feel comfortable asking an outsider because I wasn't going to see him on a day to day basis. But that was something by which I was really astounded.

INTERVIEWER: Is there anything in your career that, if you had it to do over, you'd do differently?

DR. BACHRACH: I don't think so. I've been very fortunate. I had opportunities that were incredibly wonderful experiences. I've worked with some marvelous people. The 18 years I spent with the Navy as a civilian scientist were very rewarding. I still have lifetime friends from all over the world with whom I've worked and with whom I still correspond. I don't think I would do it differently, except maybe get into it earlier.

INTERVIEWER: If you look back over the last fifty years, what single achievement in the underwater field would you say was the most significant, not just in your work, but in the whole field? What was the most significant?

DR. BACHRACH: I think that would be decompression. I think the understanding of decompression, the physiological and performance aspects of decompression were the most significant. It just allowed for much more performance and many more opportunities for diving. I think Workman's work and others, starting with Paul Bert, was very important, and I think if I had to pick one single thing, it would be decompression.

INTERVIEWER: Go back to your own career in undersea technology. If all the barriers had been removed, and you had been given complete and absolute authority to do anything you wanted, what would you have changed or done differently?

DR. BACHRACH: I can't think of anything I would have. I think that the barriers were healthy, in a sense. As I mentioned, it took me two years to have the ability to do a study on JIM. But in those two years, when I was trying to get the research proposal through to study JIM, got me into a situation in which I had to learn more about one-atmosphere diving to convince the research people to fund the study. I think that was healthy, in the sense that it made me go out and do a lot more homework. I spent twenty years in university. The freedom I had in the Navy, and the people I worked with, were much more rewarding than the university, although I cherish my academic years. The University of Virginia was a marvelous place. But in terms of getting things done, I think I had a lot more freedom in the Navy. I think the barriers were there but they were positive, in a real sense.

INTERVIEWER: In this book, we're going to look at a hundred-year time line. Pick out three events or three developments that you would say were the most significant, in the way man views undersea technology and the philosophy of Man in the Sea today. I mean, I don't want to put answers in your head but you sound like you may have mentioned one, decompression.

DR. BACHRACH: Yes, I think decompression was one. I think the work on High Pressure Nervous Syndrome [HPNS] was another because it brought reality to what we thought about undersea habitats, living cities, cities under the sea, and people still want to talk about those things. I think the HPNS told us that there was definitely a physiological barrier. We could not really expect to dive below 1500 feet, probably. I remember a MK-14 dive out off of San Diego in which they were at 1400 feet, and that was a remarkable depth. I think HPNS taught us something about what physiological events were happening with deep diving. It taught us a lot about compression.

INTERVIEWER: What about the third event that changed the way man looks at undersea technology?

DR. BACHRACH: Well, I think you can attribute the popular interest in the undersea to Cousteau and Lloyd Bridges. I think they opened up the whole world to what the undersea is about. Some people think Cousteau is the Walt Disney of diving. I think that can be viewed positively, that he did open the world to what the undersea world was about. Lloyd Bridges also helped, even though he violated a lot of safe diving practices in *Sea Hunt*, and Zale Parry, who was this marvelous wonder gal, who is still marvelous and wonderful at her age right now, I think it wasn't underwater technology as much as just making people conscious that there was an underwater world.

Underwater photography goes back to Thompson in the 1800s and Boutan, in Algeria. Underwater photography is at least a hundred years old but I think it was basically Hans Haas and Cousteau who popularized it. Well, as a technology it gave us the ability to photograph underwater and relate it to the world, and I think that was a very important step. It made the world more conscious of the underwater world.

INTERVIEWER: As we conclude the interview, give us your opinion as to what we ought to be looking for in the future and what we ought to be doing in the future in undersea technology.

Where do we need to go from here?

DR. BACHRACH: Well, I think the first thing you need to do is define the goals. What do we want from the sea? Technology has always followed problem solving or has been problem solving. I became interested in underwater time in which I'm trying to do some research. You didn't really worry about keeping time underwater until you started decompressing because the diver would go down, stay as long as he could, and come up. Right now I'm fascinated with how they keep time. I'm having trouble finding it in the logs that I've been reading. John Bevan has been very helpful in finding some old logs for me, but they didn't really tell how they did it and I'm interested in that. So, that is an example.

We didn't need the technology of timekeeping until we had the problem of compressing and decompressing. So, I think that what we're going to look for in the future is what we want to do in the ocean. Do we want to farm? Do we want to have underwater cities, about which people still create science fiction? Do we want to work on global warming? Do we want to start thinking about what's happening to the salmon industry, which is almost turning into a disaster because farming isn't working?

This is simplified, but Santayana said once that first you define what is desirable and then, within the realm of the desirable, you decide what is feasible. I think if we establish goals, like what we want to do in the ocean, the technology can follow. I don't know what we want to do. Do we want to get drugs from the sea? That's been talked about, and so has fish farming. I think the military applications have been minimal. I don't think we've ever really thought of using saturation in a combat situation. But SOSUS, and just keeping track of submarines, is a

very useful device and extremely important. There is an example of a technology that followed a problem. How were we going to study the cavitation of a Russian submarine? How were we going to track a submarine coming out of the Baltic Sea, and so on? Then, the technology followed.

One of my heroes is Jules Verne. In his writing, he was very aware of the science and technology of his age. I have written about this in the history of diving. In *20,000 Leagues Under the Sea*, Professor Aronnax and Captain Nemo are talking and Nemo says, “I’m going to send my crew out to the ocean bottom.” Aronnax asks, “How you going to do that?” He says, “By using a device invented by two of your countrymen, Rouquayrol and Denayrouze” and in the original engravings in the book, they’re wearing the Rouquayrol-Denayrouze apparatus. Well, that was patented in 1865 and the book came out in 1870. Verne had to know about the Rouquayrol-Denayrouze apparatus when he was writing the book. He’s a hero of mine, not only because of his writing, which is I think wonderful, but just because of the knowledge he had of the current technology and science.

INTERVIEWER: We need more Jules Vernes, maybe. We could use a few, couldn’t we?

DR. BACHRACH: Well, Robert Heinlein was a kind of Jules Verne.

INTERVIEWER: Who was he?

DR. BACHRACH: Robert Heinlein was a science fiction writer but he also had an engineering degree from the Naval Academy. He was a graduate of Annapolis and he wrote science fiction. He was accurate in every detail when he got into fantasizing about space, or whatever, because of his Naval Academy training.

INTERVIEWER: I have one last question. Is there anything that you haven’t said during the interview that you’d like to say?

DR. BACHRACH: No. I think I've babbled enough. I'm very flattered to be part of this and I think that *Naval Forces Under the Sea* was a very rewarding and exciting experience and I am delighted with the end product of the first symposium.

(Whereupon, the PROCEEDINGS were adjourned.)

The Reminiscences  
of  
Chief Machinist's Mate  
William Badders  
U.S. Navy (Retired)

U.S. Naval Institute  
Annapolis, Maryland  
1986

## Preface

As he brought out the first nine crew members of the 18 he was to rescue from the sunken submarine Squalus (SS-192) in May of 1939, Chief Machinist's Mate William Badders, USN (Ret.) says his first thought was for the S-4 (SS-108). He lamented the fact that the equipment he was using hadn't been available to save the six men who initially survived the sinking of the S-4 11 and a half years earlier, but perished because there was no known way to get them out. His aggressive and courageous rescue of the Squalus crew members earned Badders a Medal of Honor from President Franklin D. Roosevelt, and his selfless thought at the time of the rescue gives an indication of this man who had risked his life in the line of duty several times before. In his oral history Chief Badders gives his first-hand account of the rescue and salvage efforts on the Squalus, the S-4 and the S-51 (SS-162) lost in September 1925.

When Badders embarked on diving and salvage work in the mid-1920s, he was joining a community that was woefully underbudgeted, undermanned, and undertrained. From 1927 when the Navy finally established a full-time diving program at the Naval Gun Factory in Washington, D.C., Badders was at the forefront of experimental and practical diving and salvage in the United States. He was also a pioneer in underwater welding techniques and equipment in the mid-1930s.

But life was not all work for the athletic Badders. He played on the Pensacola Naval Air Station baseball team in the early 1920s that was one of the first teams to utilize air transportation to enlarge its circle of competition. During a 1921 cruise to Europe in the Kansas (BB-21), the crew put on non-stop exhibition baseball games for Norwegian fans. In the mid-1920s he played on the semiprofessional football team of the station ship Reina Mercedes (IX-25) at the Naval Academy. On the Asiatic Station serving in the Pigeon (AM-47) in the early 1930s, he was a contracted professional baseball player for a team in Manila where he went up against touring American pros Lou Gehrig and Satchel Paige. An injury with the Manila team sidelined Badders to coaching and managing the Holland (AS-3) team in the mid-1930s when they played against baseball great Ted Williams's high school team.

In 1940, Badders retired from active duty to take the position of master diver-salvage master for the Panama Canal, which was in the same backward state, as far as diving goes, that the Navy had been in 15 years before. Badders set up an organization, including a diving school, that kept the canal functioning for the 23 years that he held the job. One of the interesting incidents he recalls from that period was the salvaging of Anastasio Somoza's yacht, and the Nicaraguan President's kindness and generosity in return.

This finished volume is a tribute to Chief Badders's patience and to Dr. John T. Mason, Jr., former director of oral history, who conducted the interviews in 1971. The smooth typing was done by Mrs. Deborah Reid.

Chief Machinist's Mate William Badders, USN (Ret.)

Chief William Badders was born in Harrisburg, Illinois, on 15 September 1900, the son of George. W. Badders and Sarah Martin Badders. He attended Rose Poly High School in Terre Haute, Indiana. During World War I he enlisted at Indianapolis and was sworn in as an apprentice seaman on 13 August 1918. Following boot training at the Great Lakes Naval Training Center, Badders was sent to Pensacola where he performed squadron maintenance. He served as an engineer in the battleship Kansas (BB-21) in 1921 and in the station ship Reina Mercedes (IX-25) at the Naval Academy from 1921 to 1924. During engineering duty in the salvage ship Falcon (ARS-2) from 1924 to 1926, Badders assisted in the salvage of the USS S-51 (SS-162), for which he received the Navy Cross. In August 1926 when he received this decoration, he also was promoted to chief machinist's mate. From 1926 to 1927 he was back in the Reina Mercedes and played on that ship's semiprofessional football team. Badders returned to the Falcon between 1927 and 1928 and took part in that ship's futile attempt to rescue crew members from the sunken S-4 (SS-108) in December 1927. He was tapped to be first a student and then an instructor at the newly-organized Navy Diving School in Washington, D.C., and in 1930 he returned to the Falcon for a third tour, this time as the ship's master diver. In 1931 he was master diver in the Pigeon (AM-47) on the Asiatic Station and played professional baseball in Manila. He returned to the United States in 1933 and served as master diver in the submarine tender Holland (AS-3) until 1936.

During his final active duty tour at the Experimental Diving Unit at the Naval Gun Factory in Washington, D.C., Badders was rushed to the site where the USS Squalus (SS-192) had sunk in 242 feet of water off Portsmouth, New Hampshire, in May of 1939. For his dangerous role in the rescue of 33 crew members from this submarine, Badders was awarded the Medal of Honor in January 1940 from President Roosevelt.

In 1940 he went to the Panama Canal as master diver-salvage master in an inactive duty status. He remained in that position until 1962 when he was mandatorily retired at the age of 62. Badders has

been married since 18 November 1922 to the former Lavinia Emma Tydings of Annapolis. They have a daughter, Beverly Marie Badders Roberts, and a son, Albert William Badders.

## Authorization

The U.S. Naval Institute is hereby authorized to make available to individuals, libraries and other repositories of its choosing the transcripts of three oral history interviews concerning the life and career of the undersigned. The interviews were recorded on 14 and 22 September and 8 November 1971 in collaboration with John T. Mason, Jr. for the U.S. Naval Institute. The undersigned does hereby release and assign to the U.S. Naval Institute all right, title, restriction, and interest in the interviews. The copyright in both the oral and transcribed versions shall be the sole property of the U.S. Naval Institute. The tape recordings of the interviews are and will remain the property of the U.S. Naval Institute. Signed and sealed this 14<sup>th</sup> day of June 1986.

William Badders  
Chief Machinist's Mate  
U.S. Navy (Retired)

Interview Number 1 with Chief Machinist's Mate William Badders,

U.S. Navy (Retired)

Place: Chief Badders's home in Riva Woods, Annapolis, Maryland

Date: Tuesday morning, 14 September 1971

Subject: Biography

Interviewer: John T. Mason, Jr.

Q: It's certainly good to meet you, Mr. Badders. Bill Searle has been telling me a great deal about you and about your exciting career.<sup>1</sup> Would you tell me about your first contact with the Navy and your enlistment, how you happened to do this?

Chief Badders: Well, of course, this was in 1918 when World War 1 was going and I was the proper age to go in the service, so I went to Indianapolis. My home was Terre Haute, Indiana; they had a recruiting station there. Then I went through Indianapolis and I was sworn in as an apprentice seaman on August 13, 1918. I was sent to Great Lakes training station for boot training. At the boot training, they lined

---

<sup>1</sup> \*Captain Willard F. Searle, Jr., USN(Ret.), a salvage expert, is the subject of an as yet unpublished oral history that will eventually join the Naval Institute's collection.

about 300 or 400 of us up in ranks out on a big parade field, open ranks, and a couple of men walked through the ranks, looked you over and felt your muscle, and if you were healthy looking he'd have you fallout and fall into another company front. When it was allover, we had suddenly become third class firemen instead of apprentice seamen. We were going to be in the engineering branch of the Navy.

Q: You weren't consulted; you were just inspected and sent there?

Chief Badders: They figured we had muscle enough to do the job and would grow up in it, and that was it.

Then we left Great Lakes, 300 or 400 of us in a group, and went to Norfolk to a receiving ship, and from there we were sent in groups to a squadron of ships that was operating in the Atlantic. I was sent aboard the old coal-burning battleship USS Wisconsin. About 25 of us went aboard that particular ship. When we got aboard with our bags and hammocks and all our paraphernalia and were put up on the forecastle and told to sit down and wait a while; there were some people coming around with some forms for us to fill out. Before we got started on that, one of the old-timers--he looked to me to be an old-timer at that time--on the ship came over to me and said, "Hey, kid, you don't want to shovel coal on this ship, do you?"

And I said, "Well, no, not if I can help it."

He said, "Okay, when you fill that form out, you tell them that you took a lot of mechanical training in high school, manual training, that you're mechanically inclined and all that."

I said, "Maybe that isn't just true."

---

He said, "Nobody's going to check it, and that may get you out of the fireroom and get you a better job."  
Then he walked off.

So I filled the form out in that vein and, sure enough, when they began to assign us to different divisions on the ship I was assigned to the engine room division. I stood watches in the engine room instead of shoveling coal, and I found out later that was the greatest thing that ever happened to me because the fellows shoveling coal on that ship really had to work.

Q: Yes, I've read stories of shoveling coal on battleships.

Chief Badders: So I stood watches in the engine room. At first, about all I did was wipe up the oil off the floor plates and things of that kind. Later I became kind of an oiler and just a general handyman on the shifts learning as much as I could, and I became really interested in the engineering.

We cruised around the Atlantic, short patrol runs that got us in the war zone--what was determined as a war zone at that time-- which made me eligible for the World War I Victory Medal, Atlantic Fleet. We didn't really know when the armistice was signed. It was a surprise to us. I guess some people on the ship knew it, but the crew generally didn't know it. There was no excitement or anything on the ship. I heard later that other ships had big celebrations and all that, but on the old Wisconsin we did nothing. I don't even remember where she was on November 11, 1918--moving around the Atlantic, somewhere. Then we came back in to Norfolk, and I was transferred back to Great Lakes Training Station in March of 1919. In December I did various things at the training station, mostly playing baseball and things of that kind to keep out of work. I became interested in aviation and put in for the aviation mechanics school at Great Lakes.

Q: You were not like a lot of them who had the urge to get out of the service?

Chief Badders: No, I didn't at that time. A little later that comes up, but at that time I had a four-year cruise to do, and I figured that was it and I was going to have to do it. So I figured aviation was coming along and I'd try to get in that branch. Well, I didn't make the school for some reason. I never did know why, but they did send me to the Naval Air Station at Pensacola. By this time, I was a fireman second class. At Pensacola I did various things, mostly squadron work, waterfront work, pulling planes in and out of the water. They were all seaplanes there then. They didn't have planes with wheels on them in the Navy, not around there anyway. I played football with the naval air station football team and baseball, and we had the first football team that ever was transported by air. We flew out of Pensacola and went to Mobile, Alabama, and I played Spring Hill College, the first time we ever flew, and from then on we flew most places we went away from the station to play. Then we did the same thing with the baseball team. We were quite proud of the fact that we'd pull into these towns with a couple of big old F-5L seaplanes with a football team aboard. Got a lot of publicity for the game!

Q: Give me a picture of Pensacola in those days.

Chief Badders: Well, they had two branches of aviation there. They had what we called heavier-than-air and lighter-than-air. Over in lighter-than-air were blimps and free balloons and the observation type balloon. We had a couple of old Eagle boats with winches on their fantail that would go out in the bay and release these observation balloons, and they'd go up in the air.<sup>2</sup> What they did up there I have no

---

<sup>2</sup> Eagle-class patrol craft (PE), named from a 1918 Washington Post editorial calling for "...an eagle to scour the seas and pounce on every German submarine," were the result of the first American attempt to mass-produce ships. These 200-foot escort craft never made it into service during World War I and were of questionable quality, but many of the 60 ships built were used after the war as aircraft tenders.

idea. But the blimps were real active. They flew all around the country down there. And then they had a lot of free ballooning, and they would ask for volunteers to go on these free-balloon hops. They'd take off from Pensacola with as many men in the basket as they could get in, and the first time it hit the ground, they drew lots for which one was going to drop out first, and when we hit the ground one would get out and, of course, that would relieve the ballast and make it go up and maybe travel some more, and so on down the line until the last two men were in and they used their regular sand ballast to go as far as they could. The last two men when they finally landed would have to make up the balloon and get back to the air station. Some of them got quite a distance away from the station. Finally we had a disaster there. One of the balloons got in a cross current somehow and went to sea and there were about 12 men in it—10 men, I guess. We never did hear or see any more of them. That kind of knocked the free balloon on the head. No one flew with parachutes, except the lighter-than-air -people. I think they had some parachutes on the blimps, but over in heavier-than-air, where I was, we had three or four types of planes but nobody fooled with parachutes over there.

Q: Why not?

Chief Badders: Well, I guess they had them, but they just weren't issued. No one cared about them.

While I was there, Read came in with the NC-4 after his trip across the Atlantic with his crew, and that was quite big thing around the station for a long time.<sup>3</sup> That crew of men who made that trip made history at the time.

We had quite a football team at Pensacola. Some of the young college grads who were going through flight training and the enlisted men played all over that part of the country. I had a very pleasant tour of duty, but for some reason or other in March of 1921 I found myself on a draft heading for Key West, Florida, in regular service. I had never got my rate changed from regular service to aviation and I, being a kid and not knowing any different, I should have looked into that before, but it never dawned on me that I should have done that.

When I got to Key West, I found out that we were going aboard another coal-burning battleship, the old USS Kansas. But by this time I'd smartened up enough to look out for myself when I got aboard her. The same thing, when you got aboard you had to fill out a form about your past experience, your qualifications, and things of that kind, so I filled out another form that I had been in motorboats around a naval air station, which I had, and that I had some experience in aviation engines and things

---

<sup>3</sup> In May 1919 three Navy-Curtiss (NC) flying boats attempted a transatlantic flight from New York. Only NC-4, piloted by Lieutenant Commander Albert C. Read, USN, was successful, eventually making it to Portugal via the Azores.

like that. That application got me into the motorboat division, engineering motorboats, and I ended up as engineer of the admiral's barge, old Admiral Hughes.<sup>4</sup>

This Kansas was part of a fleet that came to the Naval Academy in June of 1921 and picked the midshipmen up for a midshipmen's cruise. That was one of the highlights of my seagoing career. We went from here, from the Academy, to what was at that time Christiania, Norway, now Oslo, and from there we went to Lisbon, Portugal, Gibraltar, Guantanamo Bay for a big exercise and all. Each ship had a baseball team. We used to play baseball among ourselves in port to get away if we had time enough. When we got to Christiania--I'll refer to it as Christiania because that's what it was at that time--the ambassador asked the admiral to send baseball teams ashore and play baseball for the benefit of the people because they had never seen American baseball. The time we were there, it was in the summer, of course, it never gets dark. It's daylight 24 hours a day, and we played baseball around the clock. I played 28 games of baseball in 14 days, and the only break between games was so that they could get one crowd out of the stadium and let another crowd in. We lived right at the stadium. They brought our food to us, and we stayed right there, so I didn't get to see much of Norway.

Q: It would take the pleasure out of playing baseball, wouldn't it?

---

<sup>4</sup> Rear Admiral Charles F. Hughes, USN, Commander Battleship Division Three and Battleship Squadron Two, Atlantis Fleet, in 1921. Admiral Hughes later served as Commander in Chief U.S. Fleet and still later as Chief of Naval Operations.

Chief Badders: It sure did. We tried to have some of their athletes mix in with us to play the game with us, three or four on different teams as we played along, but they didn't pick up much in the short time we were there. They enjoyed it and they enjoyed watching us. The stadium wasn't big enough for baseball. It was really a soccer stadium, and we had to have all kinds of ground rules. When you hit a ball that would have been an easy out, it would be a home run. It'd be out of the park there. During this midshipman's cruise I got very well acquainted with several of the midshipmen and I became interested in the Naval Academy, not to come here as a midshipman but for duty around here. I was told about all the boats they had at the Academy and all the athletics and all that business, and I thought, "Gee, that's the place for me to finish up my enlistment."

So, when we got back from the cruise, the Kansas was ordered out of commission. We got her put out of commission in December, and one of the rewards for doing a good job in putting the ship out of commission and all this is that they give the crew a preference of where they want the duty from that duty station. They would give them as near what they wanted as they could. Well, there were eight or ten of us on the ship who put in for duty here at the old Reina Mercedes and we arrived here.<sup>5</sup> We got it. I came to the Reina Mercedes on December 31, 1921 and did an enjoyable tour of duty here.

Q: What were your duties?

Chief Badders: By this time I was a second class engineman mate. I made first class fireman on the Kansas. Then about the time I was transferred to the Reina Mercedes, I made second class - engineman.

---

<sup>5</sup> The USS Reina Mercedes (IX-25) had originally been an unprotected cruiser in the Spanish Navy. She was captured by the United States in the Spanish-American War of 1898. She served as station ship at Annapolis from 1912 to 1957.

I went to work in the engineering branch on the old Reina down at the boathouse. The boathouse was down on the waterfront where some of the new Bancroft Hall is now; that street that runs behind the new Bancroft Hall was the waterfront street at that time. The boathouse was down at what had been a pier that went out to where the old Reina Mercedes was tied up. I operated the crew coach's boat for two years, and that was enjoyable work, but, of course, that was only part of the year. I went to Poughkeepsie with the crews. Dick Glendon was the head coach at the time I was operating the boat.<sup>6</sup> He had relieved his father, and they were quite famous crew coaches. Young Dick was very temperamental and scared the pants off me one time. We'd been up the Severn River for a workout and coming back the crew had gone way ahead of us, and I wasn't paying much attention. The coach had got out of the front cockpit and had moved to the back of the boat. I wasn't paying any attention to him back there. I was watching the crews to make sure I didn't run into any shell's oars or anything, and when I got close to the old boathouse, which was right across the street from the drill field down there at the time, I didn't have any coach in the back of the boat. Nobody in the boat but me!

I couldn't imagine what had happened, so instead of making a landing I turned around and went back as hard as I could go, retracing my steps almost to the railroad bridge, and here's Dick L Glendon swimming. I went over to try and pick him up and he ran me off. He said, "Get away from here, I'm swimming back." Well, that was still a long swim he had, and when he went overboard I really don't know--somewhere around the old railroad bridge. I stayed behind him and kept along with him all the way back anyway, although he kept hollering at me to get away from him and let him alone. I don't know yet why he jumped overboard at that point. I think he was a little disappointed with the workout or something.

---

<sup>6</sup> Richard J. "Young Dick" Glendon, Jr., was a crew coach at the Naval Academy from 1919 to 1925. His father, "Old Dick," coached crew from 1903 until 1922.

In 1924 they brought the alumni crew back to the Academy that had won the Olympics in 1920, Frawley and everybody in the crew except the stroke they had that stroked the crew in 1920, a man by the name of King.<sup>7</sup> For some reason he didn't come back. I don't know what the reason was. But they had the original coxswain and the whole crew, and they worked out for a couple of months down at the Academy. Old man Glendon came back to coach them. They were going to represent the Navy in the Olympics if they could. We went to Philadelphia for the tryouts, and they had wonderful time trials down the Severn River, and the Navy varsity shell crew at that time was great, too. We were so sure that the alumni crew was going to beat everything in the Olympic trials that they even had a cruiser ready to take the shells and the men, me, and the coach boat and everything to Paris; the Olympics were in Paris. Well, it turned out that we didn't win. Yale beat the alumni crew, and our two Navy crews came in second and third. The alumni crew--some of them were officers and some were civilians--beat the midshipmen by a quarter of a boat's length of something.

Anyway, we didn't get our trip to Paris. Instead of going to Paris, we came back to the Academy.

---

<sup>7</sup> The crew team from the Naval Academy that won the gold medal at the 1920 summer Olympics at Antwerp consisted of Midshipmen Virgil V. Jacomini '21A, Edwin D. Graves, Jr. '21A (captain), William C. Jordan '22, Edward P. Moore '21B, Alden R. Sanborn '22, Donald H. Johnston '22, Vincent J. Gallagher, Jr. '22, Clyde W. King '22, and Sherman R. Clarke '22. Midshipman Edward R. Frawley '22 rowed on the second varsity team, but was not a member of the Olympic squad.

During this tour of duty on the Reina Mercedes I served under Abram Claude, a famous name here in Annapolis, Captain Claude, and his executive officer was Henry Hartley, a lieutenant.<sup>8</sup> I got very well acquainted with Hartley, and his tour of duty was up about the same time mine was here. He told me that he was going to the only salvage ship that the Navy had, the old USS Falcon, and he would like for me to go along as the salvage ship had a lot of salvage equipment aboard, gasoline engine driven pumps, and things of that kind, and he thought I would maybe like that type of work.

Q: This meant that you had to reenlist?

Chief Badders: Yes, I had reenlisted. In October of 1924 I left the Reina Mercedes. By this time I was an engineman first class. I went aboard the Falcon in the Brooklyn Navy Yard, and I never was so sorry for asking for anything in my life as I was when I saw the condition of that thing. She was just a glorified tug, actually a minesweeper converted, and she had a recompression chamber aboard and an air system and a lot of salvage equipment<sup>9</sup>. But that was the dirtiest, hottest, most disorganized ship I've ever seen

---

<sup>8</sup> Captain Claude's first American ancestor, also named Abram, came to Annapolis from Switzerland prior to the American Revolution, and distinguished himself as an aggressive resister to the Stamp Act. Among his descendents have been an Annapolis mayor, state treasurer, and various physicians and military officers.

<sup>9</sup> The USS Falcon was commissioned as a minesweeper in November 1918 and served in a variety of roles thereafter. She was officially reclassified a submarine rescue ship, ASR-2, on 12 September 1929.

in my life. I hadn't seen very many, but I knew what a ship should look like. And I thought, "Oh, boy, I'm going to get away from this thing just as soon as I possibly can." Of course, a big lot of this trouble was the fact that she was in the navy yard for an overhaul and she was all torn apart. But, of course, I had to go aboard and report in and I was put in the engine room. The engineering department, the interim crew, was doing about 50% of the overhaul themselves. They were working like Trojans. Hartley didn't get to the ship for quite some time, and I began to worry that he wasn't going to get there. I knew if he ever got to the ship there'd be some changes made, because he wasn't going to put up with anything as lousy as that. The crew was a helter-skelter bunch of people, no discipline. Uniform wasn't heard of--you'd see them in white hats, but overalls instead of regular dungarees. Oh, it was a disorganized piece of Navy equipment.

Sure enough, Hartley finally came aboard. They had a little change-of-command ceremony, and he waited until the man he relieved got off the ship, kept the crew at quarters back on the fantail--there were only about 65 men on this thing--and he gave them a little talking-to.

Q: He had inspected the ship?

Chief Badders: Yes, and he said the same thing that I had thought when I saw the ship. He said he had never seen such a disorganized, dirty ship as the one that he had just taken over, and that he would not tolerate any such conditions; changes had to be made. He said, "We'll make them gradually, and I'm sure you people will be proud of the results, and we'll see what we can do with this." And, sure enough, before we got out of the navy yard, by the time they began to put the ship back together he had enforced some regulations about uniforms and the food, the chow and the service, and things of that kind, the

---

With a displacement of 950 tons, the Falcon was 187 feet 10 inches long and 35 feet 6 inches in the beam.

stowage of clothing, the bunks, and the quarters, and all, and it began to look like a place for Navy men. The crew did start to become interested in keeping the ship up.

We left the navy yard and went to New London, Connecticut; the Falcon was part of the old Control Force, the submarines and the submarine tenders: the Bushnell, Camden, Savannah, and the Falcon. We made a cruise from New London, and the Falcon was getting to be more like a Navy ship all the time, and by the time we got back to the navy yard for another overhaul, that was some time late in 1925, she was really a nice-looking ship and a joy to be aboard.

As I say, we were in the navy yard in 1925 for a minor overhaul. The ship had had some main engine problems, and finally the main engine was up in the shops and one evening--I don't remember the date now--we got word that a submarine had been sunk outside of Newport, just off Block Island, and for the Falcon to get there with her equipment and any divers she had aboard as soon as she could.<sup>10</sup> Admiral Plunkett was commandant of the Brooklyn Navy Yard at the time and he called the workmen in and they threw that ship together like nothing's ever been put together before.<sup>11</sup> By the next day at noon we were under way with navy yard workmen swarming all over the ship even yet. They followed them with motorboats and as one workman would finish his job he'd get in the boat, get a boat loaded, and get back to the Brooklyn Navy Yard.

---

<sup>10</sup> On the night of 25 September 1925, the USS S-51 (SS-162) was rammed and sunk off of Block Island, New York. Of the 36 men on board, only three survived. She was raised on 5 June 1926 and sold for scrap in June 1930.

<sup>11</sup> Rear Admiral Charles P. Plunkett, USN. The shipyard at Brooklyn was known officially as the New York Navy Yard. Plunkett was commandant of both the navy yard and the Third Naval District.

As I said, this Falcon was a salvage ship, but she had no divers aboard at all. There wasn't a single diver aboard her. She didn't have a lot of equipment. Gasoline-driven pumps and air compressors and things of that kind, and she had a beautiful air system permanently installed in the ship with two big low-pressure air compressors in the firerooms and a big high-pressure system aboard, but no men who had done any underwater work.

Q: This had not been thought necessary?

Chief Badders: Hartley knew it was necessary, but the Navy just didn't have that kind of people then. They didn't have divers in the Navy that amounted to anything at all. Our only diving at that time that amounted to anything at all was around Newport, where they had a crew of divers whose main job was recovering lost torpedoes from the torpedo range, and they were diving 50, 60, 70, and sometimes as much as 100 feet out there. They were about the only divers we had. The only training facility they had for divers in the Navy then was the old seamen gunners school in Washington, D.C. They put men down 50 or 75 feet with a hand pump and put them on the bottom for 20 minutes, bring them up, and say, "Okay, you're a diver." That was it, and they might never make another dive unless they were on some ship that had diving equipment and got a propeller fouled or something or to look for something that dropped overboard, something of that nature.

When we arrived on the scene where the S-51 was down, by this time it had been determined there was no one alive in the boat.

Q: How deep was she?

Chief Badders: She was in about 132 feet of water, and the divers who were out there were the men from Newport Torpedo Station--Tom Eadie, Fred Michels, and Jimmy Ingram were the diving crew at the

Newport Torpedo Station<sup>12</sup>. Ingram and Michels were in the Navy, both chief petty officers, and Tom Eadie had been in the Navy for 12 years or so and had quit and taken over the job as the diving boss at the torpedo station. They had been to the deck of the boat and pounded around on all the hatches and things and determined that there was no one alive at all, so there was no rescue operation involved here. It was strictly a salvage job. They brought cranes out from the Brooklyn Navy Yard and tried to lift her with cranes, but cranes in the open sea have never been any good, so we didn't accomplish anything.

Q: What had caused her to go down?

Chief Badders: She had been rammed by a commercial ship; the City of Rome hit her and cut her almost in two. She was on what we called at that time a ten-day patrol run, running with lights out and all that business, and was on the surface when the City of Rome hit her. The only men who got off of her were the men who were in the conning tower. It was at night, dark, of course, and the only men that got off were the men on watch in the conning tower. I think one man, maybe, got out of the hatch before they got the hatches closed. Anyway, there were five men who got out of her, and three of those five were picked up by the lifeboat of the City of Rome and two others died in the water, waiting to be picked up. The three men who were picked up said they knew that time stretched out in a case of that kind, but they were fully convinced that they were in the water over an hour before the City of Rome put the lifeboat in the water and picked them up.

Evidently, the City of Rome didn't know what she had hit and didn't realize there were men in the water until finally they heard them holler or something.

---

<sup>12</sup> Chief Gunner's Mate\_Thomas Eadie, USNRF; Chief Torpedoman Fred G. Michels, USN; Chief Torpedoman James C. Ingram, USN.

Q: What was the City of Rome?

Chief Badders: She was a coastal ship plying mostly between Boston and New York, combination passenger and cargo.

Q: Similar to what the Ward Line used to have?

Chief Badders: Right.

Well, here were all these men inside the submarine, dead, and the parents of the people and wives and so on wanted these bodies recovered, so they decided they were going to salvage this submarine. Admiral Plunkett put a lieutenant commander in charge of the job. I guess he was famous before that, but he became famous after, Lieutenant Commander Edward Ellsberg, a famous name in the Navy later.<sup>13</sup> They started to work, first, trying to recover some of the bodies. They opened the hatches, put divers inside, and they recovered some of the bodies but couldn't get all of them. A lot of places they couldn't get to.

---

<sup>13</sup> Lieutenant Commander Edward Ellsberg, USN, top man in the Naval Academy class of 1914, first came to prominence as salvage officer on the S-51 (SS-162) in 1926. He resigned from the Navy that same year, returning for reserve duty for two blocks of time and eventually retiring from the Naval Reserve as Rear Admiral in 1951. He is best known as a prolific inventor in the oil industry and author of many books, including On the Bottom (New York: The Literary Guild of American, Inc., 1929), about his experiences with the S-51. The book contains a photo of some two dozen Navy divers who were involved in the salvage of the S-51.

The system of raising a submarine was to use the Navy submarine pontoons, and seal off as many tanks as they could and get rid of as much water inside as they could to lighten the load as much as possible. What they couldn't lighten, they'd overcome with the pontoons. They worked until late in November. The weather was terrific. They worked one day and were off three, running for shelter to stop them from turning over themselves, ice cold, and the thing that made us finally have to stop altogether was that the divers' air hoses were beginning to freeze up. We almost lost a man. He was on the bottom, and his air was stopped all at once. We brought him to the surface and his air hose was full of a kind of frost.

Q: Condensation.

Chief Badders: Condensation that froze up in the hose. So they decided they'd quit until the warm weather.

The Falcon went back to New London, and we made a cruise to Panama with the submarines. We were supposed to take a bunch of young fellows, including myself, and start breaking them in as divers down in Panama, but we never did get around to that. We were too busy towing targets and towing submarines and things around for the submarine maneuvers. We never had a dive in the water. They had a grand total of six men on the job up to that time that were capable of making dives to the bottom. They were scattered all over the Navy, and they called them together for that particular job.

Q: Were you anxious to learn to be a diver?

Chief Badders: Oh, yes, I wanted to get right in the thick of things, but I didn't make out for quite a while.

We went back in the spring and went to work on the submarine and finally got her ready with all the pontoons down, and that became my job, rigging the pontoons and getting them ready to go down for the divers to work on them. That was quite a job at that time. The pontoons were not as modern as the ones we had later, and they were quite a thing to handle.

Q: How many were required?

Chief Badders: We used eight pontoons on the S-51.

Q: What was her tonnage?

Chief Badders: Each pontoon lifted 80 tons.

Q: What was the tonnage of the S-51?

Chief Badders: I don't remember, I'd have to look it up.<sup>14</sup> We got the thing all ready to blow and we were going to raise her in the morning. There were bad weather reports coming, and by morning it really was bad. Too choppy to attempt to bring the submarine to the surface, but we had a lot of leaks. You could see bubbles coming to the surface all around from some places in the pontoons and some from compartments and hatches that we had put in place. By this time I had made a dive or two.

So Ellsberg decided to go back in the morning, hook up some of the air hoses, and compensate for some of the loss of buoyancy that was in the tanks and pontoons, overcome some of these leaks.

---

<sup>14</sup> The USS S-51 displaced 1,230 tons submerged.

They hooked up to some of the bow pontoons and didn't blow more than a minute or two before there was a terrific commotion in the water almost right under the fantail of the Falcon. One man grabbed an axe and cut the mooring line leading out of the chocks on that side and let the Falcon swing free just in time, and up came the bow of the S-51 with four pontoons. I have a picture of that right over there. After this bow came up, Ellsberg decided to try to raise the stern anyway, regardless of the weather which was getting worse all the time. So they blew everything out they could and, with the bow up, put an angle on the boat because they couldn't get all the water out of the engine room that they had planned to get out due to the angle of the boat. So they went ahead and blew the after pontoons and the after pontoon chains broke and let that pair of pontoons come to the surface. Then they knew they couldn't raise her. Here she is beating herself to death up there and the pontoons are beating themselves to pieces, and the only thing to do to save her was to get her and the pontoons back on the bottom.

Sometime before that, they had closed off all the flood valves on the pontoons and they couldn't be flooded in the condition they were in to let them go back to the surface. Somebody had to get aboard the pontoons and open the flood valves so the pontoons would flood and let the bow go back, and that became my job. I volunteered, I guess. I could probably have refused to go, but...

Q: Kind of dangerous, wasn't it?

Chief Badders: Yes, because the seas were breaking together over the pontoons and they were banging together. If you got washed in between a pair of pontoons, why, you'd have had to be scraped off or something the next day or two. But you never thought of those things when something had to be done; you just went ahead and did it.

When we went back in the spring to work on the boat, Captain Ernie King, who was the commanding officer of the submarine base at New London, Connecticut, had become the overall officer

in charge of the salvage operation.<sup>15</sup> I always have thought that was one of the only mistakes that Admiral King made--he was later Admiral King but I refer to him as admiral all the time. He made me put on a great big old kapok life jacket to go out on those pontoons with a line around me to a motorboat. Of course, when those seas hit me and I was on that pontoon with that big old kapok jacket on, I could hardly hang on. I'd have been able to hang on much better without the life jacket. He thought he was making it safer for me by putting me in a life jacket.

Anyway, I got enough of the valves open to flood enough of the pontoon to put the bow back on the bottom, and when the weather calmed down we went to work again and cleared everything up. Some of the pontoons had to be brought to the surface, repaired, and put back down, but eventually we brought her to the surface and headed for the Brooklyn Navy Yard. We got within sight of the dry dock gate, and the pilot we had aboard to take her through Hell Gate ran her aground on what they called, and I guess still do, Man-o-War Rock out in the river. That created quite a problem. We had to shorten up the chains on the pontoons, let the pontoons down farther on the chains to get more lift to raise her off of this rock. That was accomplished with a lot of risk and work and some luck. While we were lowering the pontoons, we had a crane out there holding the chains up through the hawsepipes and we'd flood the pontoon down as far as we could and hold it there, then put the toggle bar back through the chain at that point. While one of these operations was going on, somebody got through the Coast Guard patrol that was out in the river keeping traffic away, went by and kicked up a swell and made the crane bob up and down and broke the sling that was holding one of the chains up, and it flew back down through the hawsepipe. It created quite a job getting the chain back up and holding the pontoon. I stood on the pontoon in water up to my neck, with my thumbs in the holes--I was actually on my knees, I wasn't

---

<sup>15</sup> Captain Ernest J. King, USN, Commander in Chief-U.S. Fleet during World War II, commanded the submarine base at New London, Connecticut, from 1923 to 1926.

standing--with my thumbs in the holes where we had taken valves off until we got some wooden plugs to plug them up until the valves could be replaced.

Anyway, finally we got everything all ready. The big rush on this was to get one of the highest tides they were going to have in the river for some long time. They wanted to catch it right at high tide and try to lift her off this rock. As it turned out, that's exactly what we did. We got this thing in dry dock, removed all the bodies and all that business. Then she was scrapped.

Well, from that work I did opening the valves on the pontoons and other work there and the work on the pontoons in the North River where she ran aground, I was recommended for and received from the President the Navy Cross. Commander Ellsberg and Hartley, when the S-51 job was completed, made many recommendations for changes aboard the submarines. For instance, the salvage air system that they had on the old S-boats, the R- boats, and the O-boats there was one fitting in the conning tower that a diver could hook a hose to and supposedly distribute air all through the submarine. Well, if that line got damaged any place in the boat, that's as far as the air went. Their recommendation was that there should be fittings on deck for air connections in every compartment and that some investigation should be made into the possibility of rescuing people from submarines in case anyone's alive when a submarine's on the bottom, and some changes in the construction of the pontoons. That was done. The changes in the pontoons were actually performed, but nothing else.

Q: What kind of changes were they?

Chief Badders: The old pontoons had only one bulkhead, in the center, which meant that when you opened the flood valves on the bottom of the thing to flood it, you had no way of controlling the amount of water you put in the pontoon, except turning the air off on the vent hose and closing the flood valves. When you get this thing heavy enough to sink itself with the water aboard, somebody had to close these valves, which meant that she was already underwater 6 or 8 feet. And that was another one of my jobs

on the salvage operation, to get these flood valves closed. They were great big 12-inch gate valves that required 17 turns to close them, and that took a long time.

Q: And meanwhile she was going down?

Chief Badders: No. They were holding her as best they could at that point. As soon as it would go in the water, they'd turn the vent off and hold everything they had on the lowering lines, but it continued to take some water in compressing the air in the top, and it would be getting heavier all the time and putting strain on the lowering lines. It would get a little deeper--we'd have them, before I could get the valves closed, go down as much as 10 feet. I'd be on a diving stage over the side, lying on my stomach, turning a big key wrench, a big long, extended-handle key wrench to close the valves and I'd be under 10 feet of water before I could get them closed.

But the new alteration on the pontoons, they put two bulkheads in some of them and in some they put a buoyancy chamber in the center, which meant you could flood the two ends and keep the center compartment dry, and you could control the amount of water you put in the two ends and make the thing weigh any tonnage you wanted. On the S-4 and Squalus jobs, we put the pontoons down weighing about eight tons, although we had to handle the lowering lines to put them down in place. That was about the only thing that was really accomplished out of all the recommendations that were made. Another thing--Hartley, seeing the big need for divers in the Navy, wanted some means of training more divers and making the ones we had better divers.<sup>16</sup>

---

<sup>16</sup> In an article in the March 1931 issue of the Naval Institute's Proceedings entitled "Some Historical Facts on Diving," pages 341-349, Lieutenant Hartley discusses improvements in diving techniques and equipment, the salvage operations on S-51 and S-4, and the Navy's recruitment and training of divers.

Q: Why did the Navy not have divers up to this point?

Chief Badders: They had no reason for them, they thought, up to then, I guess. They'd only had one submarine disaster and that was out in Honolulu in 1914. That was a little old F-boat out there, and they picked her up by sweeping wires under her and bringing her in to shallow water which required very little diving. They just hadn't had any need for divers.

Q: Had private enterprise had salvage. ..

Chief Badders: Yes. Merritt, Chapman, and Scott had their own divers, but there again I'd say 90% of their work was underwater construction work. It wasn't so much salvage, and a lot of their salvage work required very little diving. It was mostly groundings and things of that kind.

After the S-51 job was finished, I was discharged and reenlisted, and I came back to the Academy, to the old Reina Mercedes, supposedly for a football season. I played football with the old Reina Mercedes semipro team. We called it the Reina Mercedes. We had a few sailors playing, but we also played a lot of the assistant coaches, graduates of the Academy were assistant coaches, and we had quite a football team. We played all over the country.

Q: By that time you'd decided to make the Navy your career?

Chief Badders: Oh, yes. Right after I reenlisted, I found out that--in 1926 I became chief machinist's mate, part of that was due to my Navy Cross decoration.<sup>17</sup> I was on the list for chief. At that time you took examinations for chief, whatever your rate was, and you competed with the whole Navy. If you were on the list, according to the marks you made in the examination, and at the end of the year if you hadn't reached the top, the list was wiped out and you had to take another examination. I'd done that twice, made the list, but nowhere near the top but somewhere close to the top. It could have been another two or three years before I'd made it. It was part of my reward for the work we'd done--I wasn't the only one; there were three or four others in the same condition I was on the list, with different ratings, boatswain's mate, carpenter's mate. Ellsberg recommended that we be jumped off of the list to our chief grade. All of us made chief. I got chief a year or two ahead of time, ahead of what I would have normally.

During this football season, I got a knee torn up at the Academy and spent a lot of time in the hospital. I ended up being here almost a year. In fact, it was a year. In August of 1927, I went back to the Falcon, and after I was on the Falcon a short while, in 1928, the S-4, we learned, was on the bottom in New London, Connecticut. I was here in Annapolis on leave-- Christmas leave. The S-4 was rammed and sunk. She was hit by a Coast Guard patrol destroyer, what they called a rum-chaser. The S-4 was running the measured mile outside of Provincetown, Massachusetts, submerged, and the Coast Guard destroyer Paulding evidently didn't know she was in the area and ran through that measured mile area, slammed into her, and did enough damage to sink her.

---

<sup>17</sup> Engineman first class\_Badders received the Navy Cross on 2 August 1926, signed by Chief of Naval Operations Admiral Edward W. Eberle, USN, as acting Secretary of the Navy for President Coolidge. Badders was on the list for chief, but the engineman rating was being phased out. When he received his citation he was jumped off the waiting list and rated chief machinist's mate.

On her there were six men alive in the forward torpedo room.

Q: How far down was she?

Chief Badders: She was down 102 feet. I was on leave here in Annapolis, and I went right down to the Reina Mercedes and told them I had to get back to the Falcon as soon as possible. By this time, I knew the Falcon was under way to Portsmouth. While I was there, Captain King came through there. How we got together I just don't remember, but anyway we caught a plane out of Annapolis somewhere. We went aboard a seaplane and flew to Boston, and from Boston we went to Provincetown and aboard the Falcon.

Well, here were these six men alive in the forward torpedo room and no way to save them, no way of getting them out of there. The divers had hooked up the salvage air hose to this conning tower arrangement that I mentioned was on "the S-51, and when they turned the air on, it just squirted right out about 10 feet forward of the control tower at the end of the pipeline where it had been cut in two when the Paulding hit her. So there was no way of getting air into the forward torpedo room. The divers were doing different tasks on the bottom. Fred Michels got fouled up on the bottom. The seas were terrific, there was just a terrific blow, and that is one of the worst spots on the Atlantic Coast when it gets bad, right off the point of Provincetown. The Falcon was in a four-point mooring, and he had two big seagoing tugs over on her seaward side with lines running to her and trying to hold her up in the moorings so the divers could work on the bottom. She was yawing back and forth, as they tried to hold her steady, but they just couldn't do it. Fred Michels got all fouled up on the bottom in the wreckage, part of the bow of the Paulding and part of the wreckage of the S-4 submarine. He couldn't get out of there, and Tom Eadie was put back down--he'd already made one dive that morning, but he was put back down to try to get Michels freed, which he did after an hour or two. By this time Michels had a very severe case of bends, and the Falcon was tearing up her mooring lines. It was just impossible to stay

there and do anything, so they decided they would have to get out of there and they disconnected everything and left. And there were these six men aboard in the forward torpedo room, but nothing could be done. But the fact that the Navy had to leave so soon really put headlines in the papers about the Navy abandoning their men on the bottom of the ocean and all that kind of thing. Of course, the people who wrote these articles couldn't have been there and seen the conditions or they'd never have written them.

We got back as soon as we possibly could, got back on the moorings and sent divers down again. They were receiving taps, signals by hammer raps on the hull from the inside from these men for 30 hours, and after 30 hours they didn't receive any more, which indicated they had become unconscious and died shortly thereafter. By the time the Falcon got back on the moorings and got men down, it was an established fact that the men were by this time dead. Nothing could be done. So then this became strictly a salvage job, and here again we only had a very few divers, scattered all over the Navy. Myself and a man by the name of Frazer who had been on the S-51 job were the only two men in the Falcon's ship's company who had had any diving experience at all.<sup>18</sup> The other men had to be called in from all over, a couple from the Torpedo Station, Newport, and one from as far away as Honolulu came in. It was a month or more later before he got there. And we had even a civilian on the job. They put him in the Naval Reserve, a fellow by the name of Anderson, so they could use him as a diver.

Captain Savvy Saunders was the salvage officer in charge, and from all the experience we had on the S-51, the placing of the hatches and pontoons and all that kind of thing, was more or less a repetition of what we had done on the S-51 job.<sup>19</sup> It was just a matter of doing again what had been done before. She was raised very successfully and put in the Boston Navy Yard dry dock.

---

<sup>18</sup> Chief Torpedoman James W. Frazer, USN.

<sup>19</sup> Commander Harold E. Saunders, USN.

In the meantime, while all this was going on, here were all these people raising all this commotion about the Navy letting these men die on the bottom, and Admiral Brumby, one of the finest old men that ever served--by the way, he was my commanding officer years before in the old battleship Kansas when he was a captain.<sup>20</sup> By this time he was rear admiral and commanding the Submarines Control Force. He was put on the pan terrifically because, being the big man in charge, he should have facilities to do things. Of course, anybody who knows anything about the Navy knows they can only do what they have the money to do with and the time to do it and so on. At that time we just weren't spending money for that type of business.

Anyway, before this job was finished, the politicians in Washington had decided, well, we're going to do something about this, and they gave them unlimited money and time and everything else to set up diving schools and buy equipment, experiment with equipment, and all this, and really get a salvage and rescue organization in the Navy. Well, when the job was over, the S-4 in dry dock and everything, by this time Captain King was in aviation. He had just finished his flight training at Pensacola and he told me, "Look, you ought to get out of this general salvage and get into aviation."

And I said, "Well, admiral, I've got news for you. I was in aviation at one time and liked it very much, but I've never been able to get back in it."

He said, "Well, that's the thing to get into in the Navy now. Get out of this, it's too hard work. When this job is over, come over to the Bushnell and I'll get you sent back to Pensacola, get your rate changed to aviation."

Fine. The job was over and by this time, as I say, here was everything all set, we were going to go right into big schools and everything for salvage and diving...

Q: And you're going to step out!

---

<sup>20</sup> Rear Admiral Frank H. Brumby, USN.

Chief Badders: Yes. Well, I went over to the Bushnell. to see King and he said, "What do you want?"

I said, "Here's my service number and everything. You were going to send me to Pensacola."

He said, "You're not going to Pensacola. You're going to Washington with Hartley to set up a diving school. You'll do the Navy more good in diving and salvage than you'll ever do as an aviator. Get out of here." That was the end of my aviation.

Q: Were you sorry?

Chief Badders: I was at the time, but later it turned out that I was just as well pleased with the other. I went back aboard ship, and Hartley knew what I had done and I told him what I was going to do, and he said, "You won't get there because I've already arranged for you to go to Washington. I don't know when we'll go, but it won't be long."

And, sure enough, in August of 1928 I went to Washington, and we set up the diving school. By the time I got there the school was pretty well set up.

Q: Where was it located?

Chief Badders: In Washington, at the navy yard. At that time, it was the Washington Gun Factory. When I got there, I went right into the class that was in progress and came out a first class diver. Then Hartley kept me there as an instructor. I stayed there until June of 1930.

Q: How many men would be trained and for how long a period?

Chief Badders: The classes ran six months, and at that time we were using about 20 men in a class--it started with about 20 men and ended up with probably 15 out of the 20. .

Q: The others couldn't take it?

Chief Badders: For different reasons they'd flunk out, physically, mostly, and some mentally, and others just didn't have the mechanical ability and things of that kind to cut the mustard.

Q: Then, where were they being employed once they had gone I through this course?

Chief Badders: By this time, in addition to the school, they had decided--up until then the Falcon was the only salvage ship they had, but during all this big commotion thing they decided they were going to have more salvage ships, so they took four more of these same type ships and converted them just like the Falcon, put the recompression chambers aboard, the air systems, and all this business, and made billets for personnel aboard in that line of work. We had a submarine rescue vessel with each squadron of submarines. We had one out of New London, Connecticut; we had one out of Panama Canal, Coco Solo Submarine base; we had one at San Diego with the submarines on the West Coast; one in Honolulu; and one in China. Five of them we had, instead of one, and they were all in the areas where the submarines operated. And they built pontoons. They built a complete array of pontoons for each base, and supplied the ships with diving equipment and about everything we had used on the S-51 and S-4 was made available at these points with these different salvage ships.

Q: This must have automatically given greater assurance to the men who were in submarines.

Chief Badders: I think it did, although we did have problems with submarine men later.

When I went back to the Falcon after the diving school, we used to have submarine drills--this was much later after we'd devised the rescue chamber. A submarine would go out and submerge, then

the Falcon or whatever ship the squadron was with--I'm saying the Falcon because I was in her--would go out

and locate the submarine, plant a mooring around her, put divers down, hook up a hose to some particular compartment and vent that compartment, and then they'd operate the rescue chambers, take a couple of men out of the submarine with the rescue chamber, and then they would blow up different ballast tanks and raise the submarine. That was the drill. Before we'd do these drills in New London, we'd know what boat was going out and that would be all we'd know, and I'd take my divers over to the submarine, go over the thing and see what tank we were going to hook up, what ballast tank we were going to hook up to, and what compartment. We kind of rehearsed the thing. I'd try to get the chief of the boat to help me out, cooperate with me, tell me a little about the different parts of the boat, and he'd say, "Oh, the hell with it. Do it yourself. We don't need you. If anything happens to us, we'll take care of ourselves or we'll stay there." So, okay, Buddy, I'll fix you this time.

Well, they went out and they submerged and we found them. When we hooked up the air hose to the compartment, that went all right, but when we hooked up the rescue chamber we opened the hatch and then dumped a bunch of water right down the hatch. We had a lot of trouble hooking up the hose to the deck fitting; which required him laying on the bottom three or four hours: longer than he would have if he'd been a little more cooperative. We could have brought him up much quicker, but we just wanted to teach him a little lesson!

Q: A hard way to learn! '

Chief Badders: But they really had things lined up in pretty good shape after the S-4 job.

Q: Go back to the submarine school again. How deep dives did you make with the students?

Chief Badders: We went to 300 feet on compressed air. I was one of the first ones in the first class to make 300 feet. We started, of course, in shallow water and worked down to that depth. The 300-foot dive was made in the last two or three weeks before the end of the class.

Q: Where would this be, in the Potomac?

,

Chief Badders: No. These things were simulated, in water, in a tank, with air pressure, simulating the depth.

After leaving the school I went back to the Falcon in 1930, and shortly thereafter I made master diver.

During all this time the S-4 had been patched up and put back in commission--not commission, really, they took the engines and everything out of her, but her hull was tight and she had to be towed everywhere. We took her to Key West and did a lot of experimental work down there with her. Momsen had taken over the perfection of the Momsen lung, as it turned out later.<sup>21</sup> Also in Key West, we had several prototypes of rescue chambers. We had five or six different types of chambers we worked with, developing a means of bringing the men out in chambers instead of using the Momsen lung.

---

<sup>21</sup> Lieutenant Charles B. Momsen, USN, developed the Momsen lung in 1928 and first demonstrated it at the Washington Navy Yard.

We spent quite a time down there with that work and we finally ended up selecting this so-called McCann chamber out of the pile.<sup>22</sup> The Momsen lung was becoming proficient. It had been used in water down to 250 feet and had come to the surface. So the rescue end was pretty well perfected, in Key West off of the Falcon with the old S-4. And from that, they built the two lung training tanks, one in New London, Connecticut, and one at Pearl Harbor. All submarine men were trained in the use of the Momsen lung....

Q: At this point, would you describe the Momsen lung?

Chief Badders: A Momsen lung is nothing more than an air bag the men wore on their chests, with a mouthpiece, and they charged the bag with pure oxygen. They could rebreathe that as they came to the surface. To come out of the submarine, they'd have to either flood a compartment or use an escape chamber, come into the chamber with the air pocket in the top, put their mouthpiece in their mouth, and fill their air bag with oxygen similar to filling their spare tire at a gas station, and then they could duck out of this compartment hatch or escape trunk--some submarines had one and some had the other--and slide up a line to the surface, the point being to come to the surface slowly, not come too fast, breathing as they came up. When they got to the surface, they could blow this bag up. If they had used all the oxygen, they could blow it up with their mouth and keep it in place and it acted as a life preserver.

Q: How much time was given them by the lung itself? I mean how much oxygen?

Chief Badders: We used them in water as deep as 300 feet and they had plenty of air because you rebreathe this mixture, and in the lung there was a canister of material that took some of the carbon monoxide out as you rebreathed. The only gas you actually lost out of the bag was through what we

---

<sup>22</sup> The 10-foot-high McCann chamber was developed by Commander Allen R. McCann, USN, in the late 1930s and used for the first time in an emergency situation to rescue crew members from the USS Squalus (SS-192) in May 1939.

called the flutter valve on the bottom of the bag that let the excess air out as you came to the surface, to get that same pressure in that thing all the way to the surface you had at the bottom. Even in 25 or 30 feet of water, the bag would bust before you got to the surface by air expanding.

Q: There's no harm, then, in breathing pure oxygen?

Chief Badders: No, not for a given length of time.

Q: And you say that there were training centers set up in Hawaii and New London for the use of these lungs?

.Chief Badders: For training the submarine crews. Every man who qualified for submarine duty had to also be qualified to use the Momsen lung proficiently. Those tanks had 90 feet of water, and they'd come in from the bottom, lock out, and come to the surface. Of course, that was in stages. You'd do it in shallow water and work down. But every man who was in submarines had to be trained in the use of the Momsen lung.

Q: How frequently has that lung been used effectively as a result?

Chief Badders: Actually, to my knowledge, there's never been a real emergency escape with one. And in fact, now they've discontinued it. They don't use it. They found out that a man could come to the surface with nothing just as well as he can with a lung, what we call free escape. Just come up, exhaling as you come, you jump halfway out of the water. . . <sup>23</sup>

---

<sup>23</sup> The Momsen lung has been used once in a successful escape attempt from a sunken submarine. On 24 October 1944, the USS Tang (SS-306), commanded by Lieutenant Commander Richard H. O'Kane,

Q: And that's not harmful to the body?

Chief Badders: No, because they're not under pressure.

Q: You mentioned the McCann chamber. Now what is that?

Chief Badders: It's a rescue chamber that was finally perfected to the point where it was the device we used on the Squalus, to rescue all the men off the Squalus later on.

The Falcon went back to New London, operating with the submarines, and in May of 1931 I got orders' for the Asiatic Fleet. I went to Tsingtao, China.

Q: Was this something you sought? Did you want to go out there?

Chief Badders: No, nobody wanted to go to the Asiatic Fleet, particularly a married man, a family man, like me. I had two children at that time, a son and a daughter, and I didn't want to go to China Station, but somebody had to go. They only had one master diver out there. They were supposed to have four, and the one they had, his tour of duty was way overdue and he had left, so actually when I got out there there wasn't any, except me.

Anyway, I got ordered to China. I went aboard the Pigeon in Tsingtao.

---

USN, the most successful submarine skipper during World War II, was sunk by her own malfunctioning torpedo in Leyte Gulf during her fifth successful war patrol. Of 22 crew members, including O'Kane, who managed to escape the submarine using the Momsen lung, nine survived to be picked up by a Japanese ship and held as prisoners until the end of the war.

Q: And your family had to stay here?

Chief Badders: I didn't take my family out there, because the Pigeon and the submarines would operate five months out of Manila, and then we'd take a month to go to China and operate five months in China, then make the same trip back. We were operating all the time. We were out practically every day, except some weekends we'd get in. Once in a while, we'd have a week or two lay-in at Mariveles or Manila, and sometimes in China we'd lay in a week in Tsingtao or somewhere in that area.

Well, I was the only master diver on the whole Asiatic Station. I had ten first class divers on the Pigeon, 12 second class, and I had anywhere from eight to ten first class divers on Canopus. We had to keep those men requalified. Regulations required a man to make four dives every six-month period to retain his qualification, which meant we had some diving to do. In each case we'd get some projects on the bottom to try to keep the men in some kind of training for any disaster that might come along. Fortunately, we had no submarine disasters during my time out there.

Q: Incidentally, was it similar for the submarine, requiring to dive frequently, and the men got extra pay as a result? Did divers get anything?

Chief Badders: Yes, a first class diver got \$15 a month. A master diver got \$20, a second class diver got \$10, and if you made a dive more than 150 feet you got 20 cents a foot for one dive. You could only earn a certain amount of money. If you made ten dives, you only got paid for one. You could make as much as \$30 a month extra pay, but this would only happen about once every six months. But, as I say, a master diver got \$20 a month; that was as long as you were qualified.

Q: Was there any difference in diving in the Far East, as contrasted with the Atlantic?

Chief Badders: No, there was practically no difference. There was some difference in the undersea light. For instance, in Mariveles Bay we were making some night dives and using a diving light. The custom

was for the master diver to make the first dive. Then he can come up and be on deck to take charge of all the other diving operations as diving officer.

Q: He surveys the situation?

Chief Badders: Right, supposedly. So I made the first dive; I hit the bottom. I wasn't down there very long when I see all these, I thought, little eels about the size of my thumb in diameter and about a foot long and they were darting around this light. Some of them got inside the wire mesh protecting the bulb of the light, and I told them topside to take the light up, it was only creating a disturbance down there, eels and things were attracted by the light so that it was doing more harm than good. So they pulled the light up on deck, and I heard a commotion over the telephone up there, and I couldn't imagine what it was. Then I got orders to come up. I came on up waiting for decompression. It took me about half an hour to get out of the water. I'd been diving in about 160 feet of water, and when I got up, a pharmacist's mate while I was on the decompression station said, "Look at your hands. Make sure your hands are not scratched up." Your hands are the only thing not protected in the water, you know. I couldn't see any scratches or anything on my hands, and that's all he said.

Then I found out that these damned things weren't eels; they were coral snakes. I must have landed right in a bed of them because there were millions of them down there.

Q: They're poisonous!

Chief Badders: Very poisonous. They're little black snakes, they never get very big. Panamanian fishermen brought them up by the bundle sometimes in their fish nets, and they'd pick them up by the tail and knock their heads off on the side of the boat.

Q: They're more deadly than rattlesnakes!

Chief Badders: That's right. At that time, out there, they'd say if you were bitten by a coral snake, that's it, you've had it. I guess maybe I was lucky, I didn't get the least scratch or anything, but they were more interested in the light than they were in me. They probably didn't even see me; the light would blind them. While I was out there we got an SOS--we were in the China Sea at the time--and we went to see what it was all about. It was a ship on fire, apparently a Japanese ship, the Kaku Maru. The crew had all abandoned her already and was all out in lifeboats, and we went alongside and started pumping water into her. We fought the fire for 24 hours and put it out. The crew came aboard and by this time the engine room was all out of commission; the fire had burned, and the cargo had never caught fire. We had looked in the cargo hatches and the hatches were all coal from what we could see, so we figured it was a cargo of coal going to Japan.

Later this ship was brought in to Manila Bay and they started to unload this thing, take the coal out of her, and there were only 3 or 4 or 5 feet of coal on top of five-gallon cans of aviation gasoline in cases, two cans in a case. Everyone of the cargo holds was full of cans of aviation gasoline. If the fire had ever gotten to the cargo holds, we'd have been blown sky- high, everybody.

Q: What was the purpose of disguising it?

Chief Badders: I don't know, never did find out just why they did that. There had to be some reason, trying to smuggle the stuff in or tax or duty or something. I don't know.

Q: That's why they abandoned ship so quickly!

Chief Badders: Yes, absolutely. They thought the fire was going to get into that gasoline. They weren't going to stay there and try to fight it. They got off. They could have probably put it out if they'd stayed aboard and kept their firerooms going for steam for pumps. They could have pumped water, but they just

pulled fires and beat it! And they didn't tell us anything until way the next night, and our crew was really hostile with those people. We finally brought them aboard the Pigeon and fed them and let them wash up and things of that kind, and they still didn't say anything. Some other commercial company brought it in, unloaded her, and they called our skipper over.

Q: That was an example of their secrecy.

Chief Badders: Yes. There was another passenger ship that hit the rocks and turned over on her side, and we did some work on that. We didn't salvage it. The Japanese themselves went in and salvaged that. On this fire thing, I got a letter of commendation from the Commander in Chief of the Asiatic Fleet.

Q: What was that at the time?

Chief Badders: It wasn't Hart. It was the man ahead of Hart.<sup>24</sup>

Q: Yarnell?<sup>25</sup>

Chief Badders: Might have been. It was a funny thing about that passenger ship. She hit the beach and hit the rocks and she was rolling over on her side as she flooded, and never would have been completely under water, of course, because she was aground, but the passengers were abandoning this thing. They'd come down the high side of that ship on lines and hang onto those things with their feet out of the water. They threw hundreds of lines over the side, and these people would hang on the lines with their feet and

<sup>25</sup> \*Admiral Harry E. Yarnell, USN, Commander Asiatic Fleet from 1936 to 1939.

knees pulled up under their chest, wouldn't even get their feet in the water, until they'd almost pass out and then they'd drop off the lines and damned if a lot of them didn't drown. If they'd had sense enough to let themselves into the water and take their weight off themselves, we could have rescued dozens more than we did. Twenty-five or 30 people died before we could get to them. They couldn't understand what we were trying to tell them, to get in the water and hold onto the line. There were lifeboats out there trying to pick the people up and instead of picking up people they were picking up suitcases. People had thrown suitcases and great big old grass bags overboard, and the people were picking them up instead of picking up the people. The Japanese took that over and salvaged her and brought her in.

Q: Did the British have any salvage operations out there?

Chief Badders: They had some with their submarine squadron out of Hong Kong, nothing near to what we had on the Pigeon, though. Just how much they did have I don't know, but I do know that they weren't nearly as well equipped as we were. For instance, they didn't have a salvage vessel designated as such, and the only divers they had were on the tender.

Q: In Far Eastern waters, were sharks a problem?

Chief Badders: Not a problem, really. We had them. Also in Mariveles Bay I guess there's more sharks per square foot there than any place else in the world that I've ever been, but they didn't bother anybody. They were nosy. They'd swim up close to you and look around, but you make a quick move and they're gone. If you ever got excited and maybe cut one of them and started blood flowing around, that might have been a different story, they'd start fighting among themselves. But we never had anyone from the boats be attacked by a shark.

That was something in Key West when we were working on the Momsen lung, which meant that we were just in swimming trunks coming out of a tank we had on the bottom and coming to the surface. Around Key West and Dry Tortugas and all that area down there is alive with barracuda, and those things were flocking around in our area pretty rapidly. We finally became so concerned about them that

we built a big square of netting and put this tank down inside it so that the barracuda couldn't get through. They were notorious for getting things that were shiny and bright, and we had a lot of valves and things on these lungs and we were afraid they might snap at them and grab a hand or something.

Interview Number 2 with Chief Machinist's Mate William Badders U.S. Navy (Retired)

Place: Chief Badders's home in Annapolis, Maryland

Date: Wednesday morning, 22 September 1971

Subject: Biography

Interviewer: John T. Mason, Jr.

Q: It's very good to see you again this morning, sir. Now I hope you'll resume your account of your tour of duty with the Asiatic Fleet.

Chief Badders: I don't remember just exactly where we were when we cut off the last time you were here, but I believe it was diving operations in Mariveles Bay. I

Q: That is it precisely.

Chief Badders: That was just one of the many experiences we had out there. The diving conditions were not the best normally. Fortunately, most diving that we did, we had no real accidents, particularly in our Navy. We had some work to do for other shipping outfits that didn't pertain to diving. There were two cases of fire, one a grounding and the Pigeon was involved more in saving the vessel. The grounding was trying to save some of the people that were abandoning their ship. It was a Japanese passenger liner that had run aground and was turning over on the rocks as she flooded, and the passengers were slipping down the side on lines and whatnot and going into the water. The crew had lifeboats in the water, but they appeared to be more interested in picking up luggage and stuff of that kind that had been thrown overboard than they were the passengers. The consequences were that some of the people died. We never did know how many, but we did know that some few drowned.

Q: Life is considered somewhat cheaper out in the Far East!

Chief Badders: Yes. Evidently the crew just hadn't been trained in rescue, for one thing. At least, they didn't appear to be. They didn't appear to know how to handle their boats, to maneuver them around among the debris and people. It was just a very disorganized-looking operation. The captain of the Pigeon worked the Pigeon right alongside the vessel, and we took all the people aboard that we could handle. Then we layoff of the wreck for a while; then were told to get out of there, that the Japanese Government would take over, which they did. We turned the passengers over to some other ship that came alongside and we left. Some months later, we were in Tsingtao, China, with the submarine division, and they brought the ship in. They had refloated her and were noticed as she went by where we were anchored they had cofferdamed the whole length of the vessel, pumped her out, and brought her in more or less laying on her side. I understood at that time that they rebuilt the ship and recommissioned her and she went back into service.

We had one other experience. We had an SOS, got to the area, and found a ship burning. The crew had abandoned the ship and were in boats, laying off. We went right alongside and started pumping water aboard and fighting the fire. We fought the fire for about 30 hours and finally extinguished it altogether. It was mostly staterooms and things of that kind that were burning, mostly topside fires. It never did get down in the cargo holds. We had looked at the cargo and assumed that it was coal. Everything that we could see in the hatches was coal, pulverized coal, so we had no concern really of danger as far as the fire was concerned of explosions and things of that kind. This was a Japanese ship, Japanese crew, Japanese flag.

They had in the meantime brought these men who were in the lifeboats aboard the Pigeon and fed them. They couldn't speak to them very well. Very few of them could speak any English and we didn't have any people aboard who could speak much Japanese, so we didn't get many details. But they wouldn't go near the ship until the fire was completely out. We wondered why they had abandoned because it didn't appear to be too awfully bad, except it was a contrary fire to put out.

Some time later we were in Manila and we saw this same ship come in under tow and being unloaded in Manila Bay. We paid very little attention to it, except we happened to look over one day and we see small wooden cases leaving the ship in cargo nets. We wondered what they were. We hadn't seen anything like that in the holds we'd inspected. Then we went over to see what was going on. A couple of us were curious, so we got the boat and went alongside. The contractor that had salvaged this thing and brought it in had discovered that these cargo holds, particularly 1 the forward holds--I'm not sure they were all that way--were full of five-gallon cans, two cans in a case, and these cans contained high-test aviation gasoline. Evidently, they were smuggling this stuff into Japan or wherever they were going--we assumed they were on their way to Japan--and they had put these cases in the lower part of the hold and put about a 10-foot layer of pulverized coal over the top of them. We couldn't imagine any other reason for it being there except to fool somebody about the type of cargo they had.

Then, of course, it became clear to us why the Japanese crew had left the vessel. They were afraid the fire was going to get into that gasoline. If it ever had, it'd have been a real explosion.

That was about the extent of my experience of salvage out there. As I say, fortunately, we had no submarine accidents of any kind. Oh, we had the usual once or twice--mooring lines and propellers and things of that kind which were more or less routine.

The rest of our diving was just more or less a continuation of training, re-qualifying our divers. At that time, and I assume it's still in effect, first class divers, master divers, and second class divers had to make four dives every six months in given depths of water to retain their qualification. So that required about four days out of every six months for diving operations. Sometimes we got four days in succession; sometimes they'd be split up, one day a month or something like that. The first class and master divers had to make their dives in 150 feet of water or more, and the second class were required to go 90 feet and perform some task on the bottom. We used to cook up different things for the divers to do on the bottom.

Then we had scheduled what we termed search, rescue, and blow' operations. A submarine would go out and submerge on the bottom. The Pigeon would go out and locate it, tie a mooring round it, and we would send divers down to hook up salvage hoses to the compartments and circulate air through a compartment, blow a ballast tank, operate the rescue chamber through either the fore or the after hatch, take a couple of men out of the submarine. This was to keep the equipment in operating condition and the crew trained in the type of work that we would have to do if we did have an accident or anything.

Q: May I ask, what is the maximum depth for comfortable diving?

Chief Badders: At that time our first class divers and master divers--they could be qualified first class or master if they were capable of going to only 150 feet, but we preferred to have them qualified to a depth of 300 feet, and most of us were.

Q: What's the difference in technique required?

Chief Badders: The pressure effect on the men's systems was what governed how deep they could go. Some men could take more pressure than others and retain their senses of direction and capability of performing tasks. Pressure affects different people in different ways. I'm speaking strictly of using compressed air as a breathing medium, because we hadn't got into the helium-oxygen gases yet.

We tried to make our re-qualifying dives for first class and master divers between 150 and 200 feet, somewhere in that neighborhood. Very rarely did we put men down over 200 feet because it took extra time for decompression and it wasn't likely--well, you're just as likely to have an accident in 200 feet of water as in 100 feet, but it was figured 200 feet would be about the normal working depth for first class divers. We tried to keep our men well-trained and in physical condition to go 150 to 200 feet at any time they'd be called on to go down and do any kind of a task that they were qualified to do.

That just about took care of all the diving operations.

At that time the Pigeon had dual duty. Her primary function, of course, was working with the submarines on the surface, towing targets, and maneuvering with them, and things of that kind, which required the majority of our time. Although diving and salvage were primary requirements for her out there--and that applied to all the rest of the salvage ships we had in the Navy at that time--they all had other things to do that appeared to be more important than the diving and the salvage program they were supposed to carry out.

Q: Well, diving and salvage are related to emergencies, aren't they?

Chief Badders: Yes, and of course the farther apart the emergencies come up, the less interest is shown toward that type of work. You'd say, "Well, we haven't had an accident in three or four years. It looks like we're not going to have any for a while so we have other things that are more important to do."

We had other activities out there. I played a lot of golf in Manila, and some in China, not too much. I played baseball in a professional league in Manila. In China I played with the submarine division team and my team coach and manager at that time was a submarine captain, Lieutenant Roscoe Good. He later became a vice admiral and had one of the big commands in the Far East.<sup>26</sup>

We won the championship, too, by the way, three years in a row under his coaching and management. When he was sent to the Far East, I sent him a letter and told him that it was quite a jump

---

<sup>26</sup> Lieutenant Roscoe F. Good, USN, who later held the three-star billet of Commander Naval Forces Far East from 1956 to 1957.

from lieutenant and baseball manager to go up to supreme command. I had a nice reply from him that he still remembered the old days and the baseball and what wonderful duty it was.

Q: Athletics must have been a very important element for the crew on duty so far away from home.

Chief Badders: Well, it was a source of entertainment. There wasn't much for people to do out there except go sightseeing. If they didn't want to hang around the gin mills and dance halls and places drinking and hanging round with the girls, there wasn't much to do except go to baseball games or any other entertainment that the Navy could cook up. So this baseball was a great thing. We played as often as we could and practiced a lot which, in turn, turned out some pretty good teams. We had the submarine division team and the destroyer division team, and the heavy cruisers had a team. Then the individual ships had teams. Individual destroyers had teams, and they played against each other. It created quite a bit of entertainment for people that were interested in athletics.

A great number of the enlisted men played golf, particularly in Manila, at the old municipal golf course. We used to run tournaments and things out there among ourselves and we had quite a time. By the way, I made a hole in one on the municipal golf course in 1933, on April fifth, which is my son's birthday, so I thought that was quite an occasion. It just proves that a hole in one has to be all luck. It can't be science, because I was probably the worst golfer that ever golfed, but somehow or other on a par-three hole I got lucky enough to roll the ball in on my drive.

I have gone ashore on Sunday morning and played 18 holes of golf and sometimes another nine. We would play 18, then go to the 19th in the old Manila Hotel, have a sandwich and a stein of beer, and if we felt real good we'd go out and play another nine. Then I'd get out of my golf shorts into baseball uniform right in the locker room and head for the baseball park and play a baseball doubleheader in the afternoon. As I said, the league in Manila was a professional league. It had two military teams from different Army positions around there. They had a team from the Cavite Navy Yard, a civilian team from in town sponsored by one of the rubber companies, either Goodyear or Goodrich. Then the only

place in the world that I ever heard of a college playing professional baseball, the University of the Philippines team played in the league.

It was strictly a professional league, because you signed contracts and you got a salary, just like the leagues here in the States. It was a good league. It compared to, oh, I'd say AA ball in the States.<sup>27</sup> We not only played among ourselves, the league schedule, but we played independent teams that would come down from Japan. I played against the American League All-Stars. Lou Gehrig brought a team out one year.<sup>28</sup> Then I played against the colored team that Satchel Paige brought out there, two years.<sup>29</sup> I hit the longest ball I ever hit in my life off of Satchel Paige. Strictly luck again, the same as my hole in one in golf. He had a three-and-two count on me, and I knew what the next pitch was going to be. It was one of his high, hard ones that he could throw and make it look like a golf ball corning at you. Well, I started swinging when he started winding up and I , caught the ball just right and knocked it completely out of the park. The hardest ball I ever hit. We'd gather an all-star team from our league and play them, and then we'd take an all-star team from the military organizations and play them. They ended up playing

---

<sup>27</sup>At the time, AA was the top classification in minor league professional baseball.

<sup>28</sup>Henry Louis Gehrig (1903-1941), longtime first baseman for the New York Yankees, most valuable player in the American League in 1936.

<sup>29</sup>Leroy "Satchel" Paige (1906-1982), star pitcher in the Negro League from 1924 to 1948, entered the major leagues at the age of 42 and played five years with the Cleveland Indians and the St. Louis Browns.

five or six games in Manila, and then they'd go on to Japan and different places. I enjoyed playing with those colored people more than any baseball I ever played, I believe, because you could certainly learn things from them. They were, without a doubt, the finest baseball players in the game at the time. Paige would pitch not every day but every other day anyway, because, after all, he was the big drawing card. The thing about Paige, at that time he not only was an outstanding pitcher, but he could hit a ball anywhere any time he wanted to. We had some darned good pitchers out in that league. We had a couple of Marines out there who quit the service and came up and played in the Texas League. Another man who was pitching for us quit the I Navy and came up and pitched in the International League. So they had to be pretty good ballplayers. I've seen Paige stand in the batter's box until he got two strikes on him and he'd point to one of the outfielders to put him in position and tell him: that's where he was going to hit the next pitch that got over the plate. And, sure enough, he hit a line drive or a ball almost in the man's hands out there, if he didn't want to get a hit. If he wanted a hit, of course, he'd try to put it somewhere else. If he needed a run or two or he didn't need a run, it was just showmanship, he'd just drive the ball to a particular man in the outfield against one of these pretty good pitchers.

We had a lot of fun with the colored fellows. We never beat' them. We couldn't beat them. We'd come close, and they'd turn on the works and go just as far as they had to go to keep from losing. That's about all the athletics we had out there. We didn't play basketball, but we had fighters. We had fighters and wrestlers in the fleet, and they were pretty active. I never did go in for any of that. I guess I was a little old for it. I wasn't cut out for fighting and wrestling, anyway.

Q: What percentage of the men would you say went in for athletics of one kind or another?

Chief Badders: Percentagewise, it's kind of hard to say. On my particular ship there was only myself and one other man that played baseball. Our crew was too small to have a team in the ship. The two of us

played with the submarine division team. So that was two out of, say, 75. That's a darned small percentage.

Q: Yes, it is.

Chief Badders: We didn't have any fighters or wrestlers. We had 10 or 12--I'm speaking strictly of the enlisted men now--that played golf. I think just about all the officers played golf. I would say maybe 10% of the crew of the majority of the bigger ships would be in some type of fleet competition--what you'd call in school intramural stuff. They had boat crews, some boat racing, whaleboat racing and stuff of that kind. There was no track, basketball, or any of that kind of thing. I didn't even see swimming events. It seemed to me that would have been a good sport to produce out there, but I didn't ever see any of that going on. Primarily baseball and fighting and wrestling in the fleet just about took care of all the competitive athletics. Playing golf, of course, didn't amount to much.

So in 1934 I was playing ball. We were getting ready for a fleet championship, and Lieutenant Good had our team up in Olongapo getting some practice for the first championship game we were going to play the coming weekend. I used to slide when I was going into a base on a close play. I'd slide on my chest and go in headfirst and only give the baseman a hand to tag at when I went into the bag. I was trying to score on an infield ball and I made my dive for the plate. I went too far, my spikes kind of carried too far, and I rolled over. I stuck my arm out to protect myself, and my elbow stuck in the sand and shoved my arm all the way up to my neck, tore my shoulder all to pieces. I went to the hospital. They fortunately had a great bone surgeon in the Canacao hospital at that time, in Cavite, and he fixed my arm up real well. It took about three months to do it.

In the meantime my enlistment had expired--my enlistment expired before that, but they were keeping me out there overtime because they hadn't sent another master diver out there to relieve me. I think the commanding officer of the Pigeon thought that I hurt my arm intentionally to get off of the

ship so I could catch a transport to come borne. The prime thought in everybody's mind out there was what transport you were going to get to get home. I remember one time I was back on the fantail of the Pigeon sitting on a winch. I'd been fishing and I had my fishline off of the reel going down into a manhole going into what we called the after cargo hold of the ship. I'd been drying the line off, and I was reeling it back up. The captain walked back to the fantail and he saw me there with this fish pole and reel with the line down a manhole going into the after hold. He said, "What are you fishing for in there?"

I said, "I'm fishing for a transport. I'm trying to get out of here. See if I can't catch a transport."

He said, "Well, give me that rod and move over. I'm looking for one, too."

But, of course, that's not the reason I tore my arm up. I ended up doing a little over three months in the hospital and, as I said, by that time I was about four months overtime on my enlistment. They loaded me on a transport and sent me back to the States. I was discharged in San Francisco and reenlisted right away. I came here to Washington and looked around to see what kind of a billet I could get. There was nothing open at the diving school, experimental unit for a master diver. I had never had duty on the West Coast, and there was a billet open in the old USS Holland submarine tender and repair ship, for a master diver. So I asked them to send me out there and they did.

The family and I went out. We drove across country. First time I ever drove a car across the country. I bought a big old Buick and passed everything on the road but a gas station. I went broke before I got to California and had to send a telegram to friends of mine to meet me with some money in Phoenix, Arizona. I didn't have enough money to make the rest of the trip. I had enough to get to Phoenix, and when I got there I'd be broke. Sure enough, when I got there I had some money waiting for me at the telegraph office, to get the rest of the way out to San Diego.

I had a very pleasant tour of duty on the Holland. There, athletics was a big thing. I had a nice bunch of equipment on the Holland, diving equipment, and she was designed to make a lift over her

bow. She had big sheaves up in her bow that could be rigged for making a lift, I think capable of about 80 or 90 tons. We never used it during my time on the ship but it was there in case we ever needed it. I think it was there primarily to assist in changing propellers, to lift the stern out of the water for propeller changes. I never saw it used all the time I was on the ship.

There, again, diving was a very primary activity. They had also in San Diego the Ortolan, a salvage and rescue vessel the same as the Falcon and the Pigeon, and when it came time for me and my divers on the Holland to make our re-qualifying dives we were sent to the Ortolan for three or four days and we'd go out in deep water and make our dives. That's about all the diving we did in the Holland, re-qualifying dives. I used to take my second class divers out in a motorboat and put them down in 90 feet of water from a motor launch, using high-pressure air for them to breathe.

I was active again in baseball and football. I wasn't able to play much baseball at that time. My arm never did completely recover from the accident I had in the Philippines. We had a real good baseball team on the ship. We played different ships around that area and civilian teams ashore. By the way, my team--I was manager and coach of the team on the Holland--played the San Diego high school some practice games and Ted Williams was playing ball for the San Diego high school at that time.<sup>30</sup> Even then, and this was in 1936, we could never get him out. He'd just drive the ball down somebody's throat in the infield or send it out of the park. He was quite a ballplayer even when he was a high school boy. Of course, none of us ever thought at that time he'd ever become the great ballplayer that he did.

That was strictly a ship's team, and then we had the submarine division football team that operated from the Holland. All the equipment and everything was on the Holland, and the players came

---

<sup>30</sup> Theodore S. Williams (1918- ), longtime (1938-1960) outfielder for the Boston Red Sox, was the most valuable player in the American League in 1946, earned six batting titles during his career, and is a member of baseball's Hall of Fame.

from the Holland and all the submarines. We had a real good football team. Oscar Hagberg was the regular coach.<sup>31</sup> He was executive on one of the submarines at the time. He later became head coach here at the Academy. I don't remember the years he was head coach here, but he had a very successful time. I guess he might have been one of the last active duty coaches that the Academy had.<sup>32</sup> I'm not sure about that either because while all this was going on I was in the Panama Canal. But I was one of his assistant coaches for the football team. We used to leave the ship every day at noon during the football season, go to the foot of Broadway, where the Navy had an athletic field. We kept all our equipment in a locker room ashore, and we'd practice all afternoon about four days a week, and we played our games on Saturdays, sometimes on a Sunday, but generally our games were on Saturday afternoons. We played everybody. We played the different ships, the battleships up in San Pedro, and the different division teams around. We played San Diego State College, scrimmaged against them about twice a week, every week. We won way more games than we lost. Our big competitor there was the Marine Base. The San Diego Marine Base had a crackerjack team, too, but they didn't play quite the way we did. For some reason, they didn't seem to have quite the same rules. We could only have two officers on our team, whether they were playing or not. There could only be two men who were considered players on the team. That was the Navy regulation.

Q: What would be the reason for that?

Chief Badders: Well, you could pad a team up with Naval Academy graduates, stars from the Naval Academy, and have a much better team than the one that didn't have the number of officers aboard.

---

<sup>31</sup> Lieutenant (junior grade) Oscar E. Hagberg, USN, then serving in the USS Bonita (SS-165).

<sup>32</sup> As a lieutenant commander in 1944-1945, Hagberg compiled a 13-4-1 record as head coach of the Naval Academy football team. He was succeeded by another active duty naval officer, Captain Thomas J. Hamilton, USN.

And, after all, they figured that this type of endeavor was an enlisted man's activity anyway, not so much for the officers. But the Marines had a regulation that they could play two men at a time. They could have as many officers on their team as they wanted so long as they didn't have more than two playing at a time. I don't know why their regulations didn't come under the same heading as ours because I always figured a Marine was a sailor with his--well, I won't say what I was going to say--but they should have come under the same regulations we did. Anyhow, they would have some pretty good ex-college men, a couple of Naval Academy men and they played pretty good football. They used to give us about as much trouble as anybody we played. Always good clean rivalry and a lot of fun.

Well, in 1936 one of my old commanding officers from the Pigeon had taken over the experimental diving unit in Washington, and I received a letter from the Navy Department--we were on a maneuver to the Panama Canal. When we arrived in Panama and the mail came on board, I had this letter from the Navy Department, from the man who detailed divers all over the Navy, telling me that Lieutenant Commander Hollowell had requested that I be considered for duty at the experimental diving unit.<sup>33</sup> At that time, that was strictly volunteer duty and I didn't have to accept it if I didn't want it.

So I wrote right back and told them I would accept it, because I was very interested in what was going on and what was expected to go on in the experimental diving unit. When the fleet got back to San Diego, I was detached and transferred to Washington.

Q: That intrigues me. What was expected to be developed at the diving unit?

Chief Badders: Right at that time, I wasn't sure of everything that was going on, but I knew that underwater burning and welding were being developed. I had been with underwater burning in the Navy

---

<sup>33</sup> Lieutenant Commander John A. Hollowell, Jr., USN.

from the time we used it on the S-51, and I'd had about as much experience with it as anybody in the Navy at that time. I thought that I could be some help to them there in developing the I technique and equipment. So anyhow, I accepted the duty at the experimental unit, and when the fleet returned to San Diego, I was transferred to Washington.

For the first year or so we devoted most of our time to underwater burning, both gas and electric arc, and underwater welding. It just started at that time, 1936. We had many crude tools to work with, in the welding particularly, and we spent our time redeveloping these things and getting material and equipment that we could really work with. It became apparent in a short time that arc welding could be done underwater.

Q: This would be on the exterior, on the hull?

Chief Badders: Yes.

Q: Would you explain that a little more, the method?

Chief Badders: Well, it's done exactly the same way it is on the surface except that the electrode holder must be insulated from salt water, or any water, fresh or salt, and the electrode that was being used must have an insulated coating on it to protect it from the water. Otherwise, the arc would go out the side of the rod, which has happened many times, and we had a bubble in the insulating material. We used many different insulating materials, trying different things out. We started out with beeswax, dipping the rods in molten beeswax. Then we used cellophane dissolved in acetone, dipped the rods in that, and that was a pretty good insulating material. Later there was some commercial stuff that was used to dip these electrodes in. You use the same electrodes that you use on the surface welding, except in this instance it was dipped in this insulating material before it was used underwater. The method of welding was almost

exactly the same as welding on the surface.

Q: At what depth was it feasible?

Chief Badders: Any depth. Depth has very little effect on welding. Originally the idea was that you just wouldn't be able to strike an arc in water. It had to be an area where there wasn't any water. We used different things to try to make little air pockets for the electrode to work in, similar to the gas- burning torch, but, of course, that didn't work. Then we found that the arc would form itself underwater just as it would on the surface, almost the same. The arc is so hot that it created its own air pocket around itself. The thing about underwater welding, of course, is that it's cooled much quicker than it is on the surface and it becomes brittle. But I had welders in the Panama Canal--we'll get to that later but it's a good time to mention it here.

We developed welding in the Panama Canal to the point where I could take expert welders out of a boiler shop or a shipfitter's shop and make divers out of them, and they could perform welds underwater on ship hulls and things of that nature with 80% of the efficiency that they would get in the boiler shop. So that would be darned good temporary repair and, in some cases, they proved permanent.

Q: In some cases it didn't have to be done over again?

Chief Badders: Right. Then the Bureau of Mines Safety Appliance Corporation in Pittsburgh came out with a new tool. At that time, they called it the velocity power tool that drove steel projectiles into steel plates for bolting up plates over holes and hollows and things of that kind. That was a lot of work perfecting that unit. They had four or five different tools. They had one for driving in studs, one gun would drive a solid .stud in a plate with a threaded end on it, put a nut on it, slip a plate over the stud, and hold another plate down. The same gun fired a hollow stud that you could drive through the hull of a boat and hook something up to it, an air hose, and circulate air through it--a small stud, of course, but after all it would be enough air to sustain life in a compartment, which we could have done, for instance,

going way back on the S-4 job if we'd had something of that nature. We could have slammed it in the hull

of the S-4 in that forward torpedo room and circulated some fresh air and kept those men alive.

Then they had a so-called rivet expander. It would drive a stud into the center of a loose rivet and expand it, tighten it up. A cable cutter for cutting steel cable up to about an inch and a half in diameter. These things were all fired like firing a gun. The projectiles had a firing cap and were loaded with powder, and that's the secret of the whole tool. The number of grains of powder in the load determined how thick a plate you could drive a given stud into. We had studs that were good for from 3/8 plate up to 1-1/8 inch, but, of course, the thicker the plate, the more powder had to be in. These studs were all marked with the plate thickness that they were designed for.

That required a lot of time, bringing these tools to the point where they could be used. They were developed, or at least they were accepted primarily by the Navy, for fire control work aboard ship, and they could be used in many phases of salvage. I used it extensively in the Panama Canal later.

We were diving deeper in the unit by that time. Most of the men there--I guess all of them--were qualified for 300 feet when they left the diving school. We had another master diver there and myself, two masters, and ten first class divers. We were considered to be guinea pigs more than anything else when it came to diving, for working out new decompression tables to prevent the bends and other tables for treating the bends for the men who were afflicted with them.

Helium and oxygen mixtures were just beginning to see the light of day as a breathing medium for deeper diving. There had been some experiments with this gas as a breathing medium back in 1925. Gunner Tibbals and two or three men had done a little bit of work with it, but it never was developed to any extent.<sup>34</sup> But it was known that it could be used as a breathing medium, and it had two advantages

---

<sup>34</sup> Chief Gunner Clarence L. Tibbals, USN.

over compressed air--one that the men could dive deeper. When you go as far as 300 feet with compressed air, it affects the thinking ability of the men. You get two or three different symptoms. One, you're over-exhilarated; you think you can do great things and think you are doing great things when you're doing nothing except getting in trouble. Another condition is the man just more or less passes out. Oxygen exhilaration is what it amounts to, because, at that pressure, the oxygen content of the air is just too great for men to breathe. So the oxygen content has to be cut down to go any deeper, and that's exactly what the helium would do. Instead of mixing helium with compressed air, they'd mix oxygen with helium and bring the oxygen content to the percentage required for the depth the man was going. We were working with this and getting some results, not too good, but we had designed a re-breathing system for the diving helmet where the gas could be re-circulated through the-helmet and breathed over, because you couldn't just shoot helium and oxygen through an exhaust valve to the surface like you did compressed air. It was too expensive and too big a problem of supplying it.

Q: Was there any special danger, too, in handling helium?

Chief Badders: No. Helium is a very safe gas to have. In fact, I would rather have helium--our helium was all handled in steel flasks like the oxygen, and I'd rather handle the helium bottles than the oxygen bottles. There was always the possibility of fire over the oxygen and, of course, helium was just nothing. We never had any problem at any time with either one of them really, but I think oxygen would create more of a hazard at any time than helium would in storage and handling. Of course, anything under that high pressure--those bottles are charged up to 1,000 pounds--there's always the potential for an explosion of some kind, something tearing away.

We went ahead with our deeper diving with the helium, and we'd go down to about 350 feet, I guess. We had worked out recompression tables, both for diving and for treatment of bends, in the tanks

of the experimental unit, and then we went to the Falcon in New London and went out and did the same things in the open sea. That was a cold-water operation. They wanted to prove these both in cold water and in warm water. So we went to the Falcon out of New London and went up around Portsmouth and the Boston area, up in through there, and tried these tables in cold water to see if it made any difference to the effect on the human body.

Later we went to the Mallard in the Panama Canal to do the same thing. Working these tables, we'd start at 100 feet. We'd put all the divers down, like today we'd be down 100 feet and run the tables that were designed for that depth. Then the next day we'd go out to 125 feet, and 200 feet and on down. Well, we had worked up to the 200-foot depth and each time we made a new depth it had generally become my function to make the first dive at each new depth. We were making a 225-foot dive way out in the Pacific from the Panama Canal--when I say way out I mean 100 miles or so out, somewhere between the Panama Canal and Cocos Island--and I got dressed to go down. We'd been diving in the tropical waters there which are warm, of course, and I was using under my diving dress a pair of dungaree trousers and sweatshirt, well, undershorts, of course, and that was all the clothes I had on. We used our diving dress with the cuff on it and not the gloves, which meant your hands were exposed. I started down, and I got almost to the bottom on this descending line and something hit me just like ice skating and the ice had broken and I'd fallen in the water. It was just that cold, that quick. I told topside, over the phone, to stop me, there was something wrong, hold me there for a minute. Meantime I stopped myself as best I could from sliding down this line. I said, "I'm freezing down here. It's cold. I'm about to freeze." Nobody would believe me, so I said, "Well, my hands are getting numb, it's so cold, I can't control my valves. You'd better take me up out of here and find out what this is."

Well, they were still debating up there. They thought old Bill Badders had finally gone nuts or something. So I said, "If you don't bring me up, I'm going to blow up," and I began to tighten up my suit

and up I went. I was only down for a minute or two, so it required practically no decompression. I think I stopped at 10 feet for a few minutes and then came on up.

Commander Hollowell wanted to know what had happened to me, and I said, "I don't know what it was, but there's something down there. Just all of a sudden you hit cold water. It's actually so cold that you've got to be prepared for it. You've got to have the dress with gloves on it and wear heavy underwear, or you're going to be too cold to dive."

So they put a maximum and minimum thermometer down and, sure enough, the temperature of the water changed from 70-some degrees to down in the 40s. It was that Humboldt Current coming in there, underwater. They didn't realize it was in that area. So we had to move operations. We weren't getting any warm-water dive there, at that depth. We had to move out of that particular area and get warm-water diving.

We finished that operation in the Canal Zone and went on back to Washington. About that time Hollowell was detached, and Momsen took command of the experimental diving--Swede Momsen who, previous to that, had developed the Momsen lung.<sup>35</sup> Then we really got going on the helium and oxygen procedure of diving, and we were working down deeper and deeper all the time. I don't just remember the year, but it must have been 1937 when McDonald, the other master diver in the unit, and myself, made a dive apiece at 500 feet in the simulated dives in water under pressure in the diving tank, using

---

<sup>35</sup> Lieutenant Commander Charles B. Momsen, USN.

helium and oxygen, and we came out with no ill effects.<sup>36</sup> And the beautiful thing about these dives, as I said, with compressed air anything over 100 feet you would have been very inefficient. You'd have not been able to think clearly and do things that you should be able to do on the bottom. But with helium and oxygen you were practically normal, almost as normal as on the surface, and we proved that by doing mathematical problems and conversation and other things. So these 500-foot dives were made with no effects at all. Neither one of us had the bends. Our recompression table proved efficient.

Then again we left the unit and went to the Falcon in New London. We were going to make these same dives in the open sea. Here again we were working down a few feet each day. We had just got to 375 feet, I guess, and we had bad weather--fog, as no place else in the world has it like Portsmouth, New Hampshire. We just couldn't get out and operate. We had a limited number of days to use the Falcon. She had to go back to New London and operate with the submarines and our date was set and firm; we had to be finished with her on a given date. The day before our last day with the Falcon it cleared enough to let us get out to sea far enough to get in 420 feet of water, and I made a dive from the Falcon to the bottom in 420 feet of water. That was the deepest dive that had ever been made at that time in the open sea.

Then we had to get out of there and get back in, get our gear and stuff off the Falcon and drop them at New London, and we went back to Washington.

We were still doing more work with the helium and oxygen and perfecting the equipment, working on the recompression tables, and on the 23rd day of May 1939, about 10:00 o'clock in the morning, we got word that a submarine was down just outside of Portsmouth, New Hampshire, for us to stand by with our personnel and equipment for orders. We would probably be ordered to the area as soon as more details were learned.

---

<sup>36</sup> Chief Metalsmith James H. McDonald, USN, who later was awarded a Medal of Honor for his part in the May 1939 rescue of the crew of the USS Squalus (SS-192).

So we began to get what meager equipment we had together and ready for shipment. We didn't know how we were going to get up there, if we had to go. Some of the men rushed home and got a change of clothes, packed a small bag, and things and sure enough, about 11:00 o'clock it was determined that the submarine was down and there were men aboard--all hands were aboard, but some of the men were alive—and for the experimental unit, equipment and personnel, to get to the scene of operations as soon as possible.

Q: This was the Squalus?

Chief Badders: That was the Squalus.<sup>37</sup>

Three other men and I took quite a bit of the equipment over to the Anacostia Naval Air Station, and we caught a Marine Reserve amphibious plane from there and flew into Portsmouth. We got in that evening.

Momsen, Dr. Yarbrough, and Dr. Behnke and some other divers had taken another plane and got in a little ahead of us.<sup>38</sup>

---

<sup>37</sup> U55 Squalus (SS-192), commissioned in March 1939, began a series of test dives off Portsmouth, New Hampshire, in May of that year. On 23 May, failure of the main induction valve caused flooding in her aft engine room and she sank stern first to the bottom.

<sup>38</sup> Lieutenant Oscar D. Yarbrough, MC, USN; Lieutenant Albert , R. Behnke, MC, USN.

We arrived at the yard that evening, and by this time it was determined that there were 33 men alive aboard in the forward part of the submarine, but they hadn't been able to make any communication with anyone in the after part. They weren't sure whether there was anyone alive back there or not.

Q: How deep was she?

Chief Badders: In 242 feet of water.

We got our equipment in operating condition and were transported by fast boat out to the sister ship of the Squalus, the Sculpin, standing by out there, and we were waiting for the Falcon. She was in New London, Connecticut, and she was speeding to the scene of operations as fast as she could with men and equipment and the rescue chamber. She arrived sometime early in the morning and got in position for diving operations. All of us people who had come down from Washington left the Sculpin and went aboard the Falcon.

Of course, the first order of business was to see what could be done about the men who were trapped in the submarine. They had broken the telephone cable on the buoy that was released internally from the submarine. The Sculpin had picked it up, and it drifted away with the buoy too far and put a strain on the cable and broke, so the only communication was through oscillators and people hammering on the hull. But before the telephone cable had broken, Lieutenant Naquin, the captain of the submarine, had told the commanding officer of the Sculpin that he had 33 men up there and he was unable to communicate with anyone aft. He didn't know whether anyone aft was alive or not, but he knew there were 33 men alive in the forward torpedo room and all in good shape.<sup>39</sup>

This buoy cable being broken loose from the Sculpin left us with no means of knowing just exactly where the submarine was. The Coast Guard was out, and one of their boats was dragging

---

<sup>39</sup> Lieutenant Oliver F. Naquin, USN.

grapnels around and he hit the grapnel into her. They plumbed that up and down and indicated where the ship was. When the Falcon planted her moorings, they were planted around this area, of course, and then that line was used as the down line for the first dive that was made. The first business, of course, was for a diver to go down and hook up the down-haul wire and the rescue chamber, the wire that pulls the chamber down through the hatch to rescue survivors.

Sibitsky, one of the divers on the Falcon, made the first dive.<sup>40</sup> He went down this line, and after he hit the bottom, just a second or two after he reached the bottom, he said, "You're not going to believe this, but this grapnel hook is caught in the railing not more than 3 or 4 feet from the forward hatch of the Squalus, where we have to take the men out."

It couldn't have been placed any better if a diver had gone down and put it there himself. So the down-haul wire was shackled on with this grapnel line and lowered to Sibitsky and he hooked the down-haul wire up all in one dive and came up. The rescue chamber was put in the water ready for operations. The crew went aboard to operate it, a diver by the name of Harman and my later partner, operator Mihalowski, were the first two operators for the first trip. The chamber went down, and everything worked fine. We had had previous drills and all. And they brought seven men to the surface.

Q: The chamber could accommodate that number at one time?

Chief Badders: That's what it was designed for, seven passengers and two operators. I was put in the chamber for the second trip with Harman, and I got to thinking on the way down I had operated this chamber probably more than anyone else in the Navy and I knew that it could handle more than seven men. On the way down to the hatch, I decided that I was going to bring more than seven men out on my

---

<sup>40</sup> Boatswain's Mate Second Class Martin C. Sibitsky, USN.

trip, for the simple reason that if we only brought seven men out at a time, it was going to require a fifth trip to get all the men out. I knew that they could be brought out in four trips if a man or two extra was brought out in the other trips.

Q: Was oxygen inside becoming an urgent thing?

Chief Badders: No, no. In the rescue chamber there was atmospheric pressure all the time. There was fresh air circulating.

Q: No, I mean within the submarine, so it became imperative to get them out.

Chief Badders: Oh, no. There was no apparent danger to the men. The first trip down, fresh air was circulated through the compartment from the rescue chamber. Clothing, blankets, food, and things of that kind were given to them. The only danger that we thought about was that there's always the possibility of a bulkhead carrying away or something and flooding that area, or gas getting in.

My concern was to get the men out of there as soon as we could because--fortunately, in this operation we had good weather at that time, but there's always a possibility of one of those crazy squalls coming up that they have in that area and having to run to get away with men alive on the bottom. So on my first trip, I brought nine men up. I hadn't said a word to anybody on topside about it, but I came up with the nine men with no difficulty at all, unloaded them, still hadn't said anything. Of course, they're counting these men when they get out of this chamber on the deck of the Falcon. We unloaded them out of the chamber on the deck of the Falcon, and a doctor would examine them real quick. Then they'd load them up and take them to the hospital in Portsmouth.

Well, I was also going to make the third trip in the chamber, and I knew that when I made the second trip. I got the men out of there as soon as I could, dogged the hatch down, and got started down again. I think it was Momsen who said to me on the phone, "You brought out too many men on that trip, but do it again and bring up nine the next time." So I brought nine up on the second trip, which left only

two trips required to bring the rest of the men up. I brought 18 men out of there, out of that sunken submarine. There are their autographs on the wall, on that list of survivors.

Well, on the fourth trip, the operators went down to bring the last survivors out, and on the way up the chamber got fouled up in the down-haul wiring. The down-haul wire got in the gears of the drum somehow or other and fouled the chamber. It couldn't go up or down, so we had quite a time getting that chamber-load to the surface. It took three or four hours to get them up. We had to send a diver down to cut the down-haul wire loose at the submarine, and the chamber had to be pulled up very carefully, because if it came up too fast it could displace water out of the ballast tank and cause some damage or something.

The next day, after all the survivors were off, Admiral Cole, who was the admiral in charge of the operations--he was commandant of the Portsmouth Navy Yard at the time--said, "We've got to determine if there's any life left aft in the submarine. It will require a trip of the rescue chamber, open the hatch aft, and determine for sure if the after part of the submarine is flooded or dry."<sup>41</sup> Well, some overhaul work had to be done on the chamber to replace this down-haul wire and everything, and they waited until the next morning. They did this work during the night, and the next morning Mihalowski and I were selected to make this so-called fifth trip with the rescue chamber to the after hatch. The down-haul wire was hooked up, and Mike and I got in the chamber and down we went.

To make this trip, the chamber had to be secured over the hatch and then pressure built up in the chamber equivalent to bottom pressure; otherwise if you unscrewed that hatch and the after part of the submarine was flooded at 240 feet of depth, and the rescue chamber was under atmospheric pressure, the water would have come right up out of the submarine into the rescue chamber.

---

<sup>41</sup> Rear Admiral Cyrus W. Cole, USN.

So we had to sit the chamber down in place over the hatch, dog it down with the holding-down bolts, and then build a pressure up in the chamber equivalent to bottom pressure. That meant that Mike and I were in the chamber with pressure built up to 240 feet aft and bolted to the submarine with bolts internal. If we had become incapacitated or passed out from compressed air, we'd have been hooked up down there just like the men in the submarine and no way of getting us out. But fortunately nothing happened.

We got everything all set and let the pressure build up, then opened the hatch and, sure enough, when I first partially undogged the hatch a gush of air came out of the submarine into the rescue chamber. I was down in the lower compartment of the rescue chamber handling the hatch. Mihalowski was handling the valves, pressure gauges, and all in the top compartment, and he hadn't built up quite enough pressure; otherwise the air wouldn't have come out. As soon as he built up a little more pressure in the rescue chamber, the air stopped coming in, and I opened the hatch the rest of the way and it was flooded right up to the neck of the hatch, which indicated there couldn't possibly be any life down there.

We made a report to the topside, dogged the hatch down, released the rescue chamber, and came on to the surface.

That indicated that rescue operations were finished and it was strictly a salvage operation in bringing the submarine up, which we did. We went to work on it with pontoons, drying as many compartments as practical with ballast tanks and whatnot, and raised her. That's a long story of salvage and I don't think you want me to go into too many details of this. I think everybody's read about the salvage of the Squalus.<sup>42</sup>

Q: Yes.

---

<sup>42</sup> See Edward Parks, "Fate Toyed with Squalus Crew on 19th Dive," Navy Times, 3 March 1986, pages 10, 32, and 36. The article is accompanied by paintings which depict the rescue chamber and its attachment to the submarine.

Chief Badders: She was successfully raised.

Q: That must have been a thrill, though, to rescue the 33 men.

Chief Badders: Oh, you know, the first thing I thought of when I made my first trip with survivors, when I opened that hatch and the first couple of men came out of that submarine into the rescue chamber--the first thing that entered my mind was, boy, just why couldn't we have had this when we had those six men alive in the S-4. They had to finally die down there because we had no way of getting them out. If we'd just had that rescue chamber then, we could have saved those six men just as easily as we saved the 33 on the Squalus, in fact much easier because she was only down in 102 feet of water. And we should have had that chamber then because things of that kind had been suggested after the S-51 job, but absolutely nothing was done about it. I'm not blaming the Navy for this, because the Navy can only do what it has the money to do and time to do it, and there just wasn't anyone interested in giving us the money and time to develop things of that kind.

Q: Mr. Badders, with the use of helium and oxygen, what has become the maximum depth for a diver?

Chief Badders: I was just reading in this magazine that there were two men down 1,600 feet for something like 10 or 12 hours. They have gone into now, of course, what they call total saturation. It's supposed to be new, that is in the last two or three years they've gone into it extensively, but we knew that we could do that back in 1938. We knew that the human body would only absorb so much gas, and then it wouldn't absorb any more regardless of what depth the diver was or what pressure he was under or how long he stayed there. We had more or less accidentally discovered that, and it was familiar, but we didn't pursue that procedure.

It became apparent from these deep oil well operations and some of these things that required diving operations that men had to go deep and stay a long time to get anything done. We needed some operating procedure that could prevent this short time on the bottom and extensive time in decompression, which made these operations cost so much money that they were impractical. So they began to experiment with this total saturation thing. They'd put a diver down, for instance, to 300 feet and leave him there until he had absorbed all the gas that his system would absorb, and then he could stay there for a week or two, 10-15 days or longer, for that matter, without absorbing any more gas.

In other words, from that time on decompression time wouldn't change coming up appreciably. So that's the way they're working it now. They're going down and they have a job to do in, say, 200 feet of water and the men are totally saturated on the surface before they go down in chambers. Then they go down in a pressurized chamber, open the chamber, and whatever type of diving equipment they're going to use for the job, work six or eight hours, if they want to, or whatever the work requires, and back into the chamber, bring them to the surface and hook them up to the dry chamber on the surface, keep it under the same pressure all the time, feed them, change clothes, whatever. And while they're up another team of divers is down under the same conditions. They keep rotating in that manner until whatever job they're on is completed. Then they go into the long-drawn-out decompression requirements on the surface to bring them back to normal pressure.

Q: Do temperatures become a factor at these great depths?

Chief Badders: Very definitely, but the Navy and civilian concerns have developed means of keeping the divers warm electrically. I think they're still in the electrical field, but mostly circulating warm water through a part of the clothing that they wear, heating elements that keep the water at different temperatures required for the bottom to keep them warm. The deep-submergence outfits on the West Coast, the Navy's Sealab is a total saturation thing. They go down 15 days or more out there.

Q: For the individual diver does the underwater life constitute an obstacle of any kind?

Chief Badders: You mean detrimental to the health in the future?

Q: Well, I mean to the effectiveness of his operations as a diver? Sea life, sea creatures, what have you?

Chief Badders: Oh, no, they haven't been bothered in any way. There are a lot of wild stories, mostly fictional, about divers being attacked by manta rays and sharks and things of that kind, but actually I don't know of one case where it actually happened, where a diver was attacked by a shark or manta rays or anything of that kind. An octopus will wrap around a guy once in a while, I guess, if he gets around a big one, but that's no problem. They can cut themselves loose or get away somehow. We've had no real casualties in that way; that's for sure.

Q: About the time you were talking about, the French diver, Piccard, was operating, was he not?<sup>43</sup> Did we learn anything from his operations that was useful to us?

Chief Badders: I think the most we learned from him was how to build pressurized vessels to keep men under atmospheric pressure and put them down for observation at great depths.

Q: He had his bathysphere?

Chief Badders: Right, and from that have come these high-pressurized units that are going down 15,000 or 20,000 feet now. I think that's an offshoot from his original exploratory work.

---

<sup>43</sup> Auguste Piccard and his son Jacques established a world record, since broken, for descent into the sea when they took a bathyscaphe to more than 10,000 feet below the surface in the late 1940s.

The work that he could do from the inside of a vessel of that type was very limited. The fact of the matter is I don't believe he had any means of performing any task other than observation. It could be used for directing operations from topside, for instance, lowering explosives and putting them in the proper place, things of that kind, or hooks to hook into objects on the bottom and things of that kind.

Since the time of his first work in that line, they have developed mechanical arms and things that they are using pretty successfully for a lot of different tasks on the bottom. My understanding is that the Navy is working right now on units of that kind that will be almost purely mechanical; there will be no outside help at all from the diving angle. All the work will be done from inside of a pressurized--pressure-proof--vessel through mechanical means of electronics and mechanically-operated arms. They're doing great things.

Q: So the individual diver will not have to operate outside the lab?

Chief Badders: Not at great depths. I'm speaking of depths of 10,000, 15,000, 20,000 feet. I don't believe the time will ever come that we're going to get divers down and perform any useful tasks out in the water any deeper than 1,000 feet. I don't believe it's going to work. Things are happening to human bodies that have been exposed to these pressures, and it just hasn't been determined yet what these effects are going to be in the future on a man's system.

For instance, not long ago a man was down over here in Washington in a normal dive; it was 200, 300, or 400 feet. He came up and everything was supposed to be perfectly normal, but the man is stone deaf. He never has regained his hearing, and the last I heard of it there is no indication why he had gone deaf. His eardrums weren't ruptured, nothing that they found. It had to be some action on the nerves, I suppose, but it didn't show up on examination. He was stone deaf, and it still seems he'll be permanently deaf--a chief petty officer with about 18 years' service.

Q: During your period of activity as a diver, were there any limitations on the length of time that a man could normally engage in diving? Was there anything of this sort that began to develop?

Chief Badders: No. We had no real permanent effects on anyone. Practically all of us had the bends from these experimental tables we were running. You couldn't tell how far a table would go until you went to its limit and saw what would happen, and sometimes we would get the bends. I had the bends several times pretty severely, but proper decompression and recompression overcame it and, as far as I know, I don't have any effects from any of that. I have a very bad shoulder and neck right now in the area where I was hit the most often and the hardest with the bends, and I sometimes wonder if that didn't have some effect on my condition now, but any doctors that I've talked to say no, it's something else. So during my work we had no aftereffects that amounted to anything at all. Nothing that wasn't cured in time.

We had one man who went into shock and he was not in bad shape, but some of his faculties didn't work the way they should for a couple of months. But he eventually recovered, totally recovered, as far as the doctors could determine.

Q: So, unlike an athlete who has a limited period of time for his profession, the diver isn't limited in this way at all?

Chief Badders: Not time so much, but age. During my time--and I think it's still in effect--first class and master divers, when they become 40 years old, are automatically disqualified for deep diving, but they can be waived. Those regulations can be waived if he is still in physical condition to go ahead. That happened to me. While I was still in Washington I was 40, and agewise I was supposed to be disqualified, but the doctors found me in excellent physical condition. You had to be examined every three months, once a quarter, to make sure that you stayed in that condition.

Q: What is the thinking behind a regulation like that? Why 40 as the cutoff date?

Chief Badders: I really don't know. It's like everything else in the Navy. If something weighs a certain amount and a certain sized wire will lift it, well, we'll use a wire twice that big to do it for safety. So I think maybe a man might go to 50 or 60 years old and still be all right, if he's physically all right, but the Navy says, well, it can be done that far, but let's make it safe and cut it off at 40, which, in some cases, takes men out of service that are right in their prime, if the regulation was pushed without his waiver thing.

I don't know if that waiver is still in effect or not, but I believe it is because I see men around Washington that I'm pretty sure are over 40 years old. At least they're instructing and making some dives. I suppose that the doctors figure when a man gets 40 he has begun to deteriorate and he shouldn't speed up the process. I know in my case I felt, and it was proved by all the physical exams that they could give me when I was 40 years old, I was in as good shape as I was in my 20s--I felt as good or better.

Q: And you had much more experience and wisdom to empty.

Chief Badders: Right.

Q: How long did you continue to dive, actually?

Chief Badders: Of course, I wasn't doing any deep diving in the Panama Canal, but I was diving not too regularly but regularly enough up until the time I retired when I was 62 years old. Of course, there again, as I say, diving down there was shallow diving, mostly ships' hull inspections and some construction work that would take you down maybe 60 or 75 feet.

I had one job in the Panama Canal that came up a couple of times, one of the dams that required diving to 120 feet. That was the deepest we ever had in the Panama canal. I was considered to be in very good condition when I retired in the canal. Down there you have to retire when you're 62 years old.

I knew I was good for five or six more years in my job down there, but there again somebody said age is age, and that's it regardless of who you are. Like my automobile out there. I've got a 1968 automobile that's a better automobile than a lot of 1971s that are running around today, and it's the way I've taken care of it, and the way I take care of myself has to do with my physical condition.

Q: You said that Admiral Cole had the Squalus put in dry dock on your birthday in Portsmouth.

Chief Badders: Well, previous to that we had had quite a problem of getting a line under the stern of the Squalus to get the chains in position for the pontoons. It was too deep for the tunneling operation that had been done on the S-51 and S-4 jobs for working the chains under, and we were trying to work a line under the stern with a lance, a combination of water and air being forced under the submarine. As I say, we had quite a lot of trouble with this thing and had consumed an awful lot of time, and the day that we finally completed the operation, the lance completely circled the stern, under from one side and up on the other side, and we knew we were going to get a line under the boat, happened to be the morning of Admiral Cole's birthday. He hadn't come out to the operation that morning, so I sent in a message to him, a personal message myself, congratulating him on his birthday--I forget what birthday it was now, but he was getting up in age and retired right after the Squalus job--and said the lance is completely around the submarine, we'll have lines under it by tomorrow, and signed it Bill Badders.<sup>44</sup> He was so pleased with that and when we got the submarine in it was supposed to arrive on the 14th and he said, "I want to get that thing in dry dock tomorrow, on your birthday." It turned out that there was a lot of work to do to get the submarine itself ready and the dry dock, mostly work on the submarine, getting the pontoons off of her and getting her on an even keel and in proper trim for going in on the blocks. So we

---

<sup>44</sup> Cole was born 21 June 1876.

had to work real late that evening so as to be sure and get her in on the next day, the 15th of September, which would be on my birthday, so that was my birthday present from Admiral Cole.

Interview Number 3 with Chief Machinist's Mate William Badders, U.S. Navy (Retired) j

Place: Chief Badders's home in Annapolis, Maryland

Date: Monday morning, 8 November 1971

Subject: Biography

Interviewer: John T. Mason, Jr.

Q: It's good to see you again this morning, Mr. Badders. Last time, you gave me that most interesting account of the rescue from the Squalus and you concluded your remarks at that time with the dry-docking of the Squalus on the 15th of September 1939. Do you want to resume the story from that point?

Chief Badders: A couple of days after the Squalus was placed in dry dock, our group, the experimental diving unit group, left the Portsmouth, New Hampshire, area and returned to our duty station at the experimental diving unit in Washington, D.C. We had two or three weeks' work getting our equipment cleaned up and overhauled and back in working order that we had used on the Squalus.

Q: And the inevitable reports, too, I suppose?

Chief Badders: Yes, miles and miles of reports to be made. Rough logs had been kept, of course, of every activity and every phase of the operation. That all had to be smoothed out and shortened up for the bureaus concerned, and that took time. So we really didn't accomplish much the rest of the year in the line of diving.

We had made the two deep dives previous to the Squalus disaster, and it was determined that we wouldn't go that deep again with the equipment available at the experimental unit. The diving tank wasn't built for that pressure, so we had gone as deep as we could.

Q: That being 500 feet?

Chief Badders: Five hundred feet, right, and it was a matter of perfecting some of the tools and some of the procedures that we had inaugurated on the Squalus job, smoothing some of them out and getting them ready to be approved by the bureaus and adopted as standard procedures and standard pieces of equipment for future use in the Navy. It didn't take long for the end of the year to come along. In the meantime, there were ceremonies in the Navy Department and different places, different men were decorated for different phases of the operation. The divers received Navy Crosses late in the fall, and I guess it was sometime in late November or early December that we got the word that four of us were definitely going to be decorated sometime in the near future with the Congressional Medal of Honor. Of course, that put us on edge. That was pretty great.

On the ninth of January 1940, McDonald, Mihalowski, Crandall, and myself went to the White House and received our Congressional Medals of Honor for the work that we had done in the rescue and salvage operations on the Squalus.<sup>45</sup>

By this time the war was inevitable and we were sure we were. . . .

Q: And the presentation was made by the President?

Chief Badders: Right, President Roosevelt.

Q: Can you recall the incident?

---

<sup>45</sup> The other Medal of Honor winners were Chief Metalsmith James H. McDonald, USN; Torpedoman First Class John Mihalowski, USN; and Chief Boatswain's Mate Orson L. Crandall, USN.

Chief Badders: Well, the incident at the White House didn't amount to very much, because the President was not well. He was very ill, and we didn't even have the news media or photographers there. He presented the medals and shook hands with us and gave us a little pat on the back, and from there we went to the Secretary of the Navy's office in the old Navy Building and then the whole thing was done all over again with him presenting the medals with the news media and the newsreel cameras and all of that. That's this picture over here on the wall, the Secretary of the Navy hanging the medal around my neck.

Q: Who was the Secretary of the Navy?

Chief Badders: It was Edison.<sup>46</sup>

So we began to work with different gas mixtures, making different dives and testing our recompression tables, and whatnot. Several of the men were transferred to other activities. Two or three of them, the so-called guinea pig crowd, the personnel attached to the experimental unit were sent out to different billets. New men came in.

I got the word that the Panama Canal wanted a master diver-salvage master. At that time I was a senior master diver in the Navy, and they anticipated sending me to the Panama Canal for the job that they wanted to set up for the war effort there. Well, I figured that I wasn't going to be around Washington very much longer; I'd be at the Panama Canal. Sure enough, in early March 1940 it was determined that they wouldn't send me down there on active duty. The governor of the Panama Canal, being an Army general under the Army Engineer Corps, wanted a man there that no other branch of military service would have any jurisdiction over. In other words, when he got a man there, he wanted to

---

<sup>46</sup> Charles Edison, son of inventor Thomas Edison, was Secretary of the Navy from January to June 1940.

be sure he was going to keep him there. He didn't want naval orders to come in transferring him away about the time he got an organization set up.

Q: One would be under Civil Service then?

Chief Badders: Right. So they transferred me from the regular Navy--at that time I had 22-1/2 years of active duty--to the Fleet Reserve, which put me in a civilian status and, of course, still subject to naval orders.

Q: How did you feel about that change of status?

Chief Badders: At the time it was going on, I was very enthusiastic about it all. I thought, "Gee, this is great. I'm going out here with 22 years' service. I'm going to draw my 22-year Fleet Reserve pay, and I'm going to draw a salary from the Panama Canal." In the meantime, I'm going to be doing something real great for the war effort, if things go on the way it had been explained up to then.

Q: You didn't mind the idea of the Panama Canal?

Chief Badders: Oh, no, I had no regret about being considered for this. In fact, I thought it was quite an honor. I went through all this procedure and went into the Fleet Reserve on the 12th day of March, left New York City the 13th day of March for the Panama Canal. There wasn't a day lapse of service between active duty in the Navy and on the payroll of the Panama Canal.

Q: Did you take your family with you?

Chief Badders: Not at that time. My family couldn't go down there until I had been on the job long enough to provide quarters for them. All employees of the Panama Canal had to live in what they called Panama Canal Government quarters, and people were coming in there by the thousands for new construction projects for the defense of the canal and so on, which meant that the place just didn't have quarters available for everybody immediately that went in there. That was the only unpleasant thing about the whole deal.

Immediately upon my arrival at the canal, they laid out the program that they had in mind. They wanted a diving organization--diving and salvage organization--to keep the Panama Canal open under any conditions. If we had ships bombed or lock gates damaged by bombing or sabotage or ships ramming or anything of that kind, we had to make immediate repairs and keep this thing open. The governor told me at the time, "Put in simple words, your job is to keep this canal open from Buoy 1 Atlantic to Buoy 1 Pacific. Whatever it takes to do that, you have the funds and the backing of the organization here to get the people and equipment to get ready for it."

Q: I take it there wasn't any such organization in being then.

Chief Badders: The only divers in the Panama Canal was one diver at each set of locks to do minor repair work in the locks--pick things that were dropped in the lock chambers, unplug valves that were jammed up, and things of that kind. I guess there were about four or five divers in the whole Panama Canal.

Q: Were they Navy divers?

Chief Badders: No, they were civilian divers, employees of the Panama Canal, and they were so far behind they were still using the old hand pump system of diving, men turning the hand pumps cranking air down to them. This was in 1940, and that's how far behind they were.

Q: What had they done in the case of a real salvage job?

Chief Badders: They hadn't had a real salvage job in the canal up to then. They just hadn't had anything other than groundings, and they don't require much diving generally. It's a matter of pulling and tugging and getting the thing floating again, unless the ship is damaged, has a hole knocked in it when it went aground. But they hadn't had any problems like that down there.

By this time they were having all this bombing over in Europe, plugging up harbors and stuff of that kind, and they didn't want it to happen in the canal. They just couldn't have it happen, because in addition to the Navy ships going through the canal both ways, the merchant ships, tankers, and troopships and things of that kind just had to get through. Otherwise, as you know, they'd have to go all the way around the point and it would take days and days longer to transport material and people. So I went to work drawing up a plan, and when I'd finished with it, it was approved. My first main function was to establish a diving school. You couldn't hire divers. There weren't any available anywhere by that time. I had to build a diving school, make up the curriculum, designate the qualifications of the candidates for the diving school, and so on. That was all approved not only by the Panama Canal, but my curriculum was sent to the Navy Department and the Navy approved of it to the extent that they allowed me to use the same curriculum putting Navy people through my school in the Panama Canal, if and when we had space available and the time to train them. And I did; I trained over 100 Navy men down there and made salvage or second class divers out of them.

Q: How many men did you feel that you needed for your project?

Chief Badders: We figured we were going to need about 50 men on hand at all times to be absolutely safe, which I never did reach--never did reach 50. I put a class of people through--let me go back to establishing the school, first, before I go into that.

We had to have a lot of equipment, air compressors, welding machines, pumps, and things of that kind, and by this time these things were hard to get. There was high priority on them for other purposes all over the world. And the Normandie turned over at Pier 88 in New York, and that was a major salvage operation.<sup>47</sup>

Q: Indeed it was.

Chief Badders: I went sent up there as an observer on that job and to be associated with, at that time, Commander Sullivan, who was in charge of that operation, and get a line on the equipment that would be most suitable for our operations in the Panama Canal.<sup>48</sup> I was there about six weeks, I guess, running from there all over the United States to different manufacturers of pumps and welding

---

<sup>47</sup> The French luxury liner, SS Normandie, was seized and interned in New York at the outbreak of World War II. In December 1941 she was designated as a Navy transport and renamed USS Lafayette (AP-53). During conversion she caught fire on 9 February 1942 and as the result of a chaotic and poorly planned fire-fighting effort, she was overloaded with water, keeled over and sank at her slip. The Lafayette was righted in August 1943 and reclassified APV-4, but had been so extensively damaged that plans to complete conversion were stopped. After the war she was sold to a New Jersey company for scrap.

<sup>48</sup> Commander William A. Sullivan, USN. Sullivan's oral history is in the Columbia University collection.

machines, picking up what we could for the canal. Sullivan helped us a lot by allotting quite a bit of the Navy-procured equipment that he transferred to us.

Well, I got back to the canal and my diving school building was about completed. I was building the school on the banks of Gatun Lake, right adjacent to the only ship that had ever sunk in the Panama Canal. She was lying on the bottom right at that area, a little old combination freighter and passenger ship that somehow started leaking coming through the canal. They ran it over against the bank, and it turned over and slid down to the bottom. They never did anything about bringing it up, so I thought that would be an ideal place for a training ground for training divers.

In the meantime, before I left to go to New York, I had drawn up the qualifications a man would have to have to enter the diving school. He had to be under 30 years of age. He would have to be a man who had completed an apprenticeship and served. at least a year in his trade, and the trades that were more apt to be used underwater, such as welders, burners, riggers, shipwrights, carpenters, machinists, pipefitters, shipfitters, those ratings. When I came back, I had over 300 applications on my desk to sieve through for people who met that much of the qualifications.

Q: Where were these people?

Chief Badders: Allover the Panama Canal. All the employees of the Panama canal, the different shops and activities of the Panama Canal.

Q: Oh, they were all there, within the family, so to speak?

Chief Badders: Oh, yes. All the men were already employed by the Panama Canal, but the ones that I selected would be transferred to me for each class that I ran.

Q: And what was the inducement for them? Was it higher pay?

Chief Badders: Slightly higher pay than they were making in the shops. Oh, I'd say a half more. And I suppose it was considered a kind of glamorous job at times, interesting at least.

As I said, I considered that I wanted about 50 men available who were qualified divers, and I set my curriculum up originally so that it would be about a three-month course of instruction. By this time the war was really going. Pearl Harbor had been hit by the time I finally got the diving school and everything all organized. So they said, "Well, we can't take three months to make divers. We've got to have some men that can do something in a shorter period of time than that. What are you going to do about it?"

I said, "Well, I'll take a class with the equipment I have and the personnel I had on hand." I figured I could handle 12 divers, and I trained the diver tenders at the same time. By the way, the diver tenders were supposed to have been apprentice boys, men who were in the apprentice program for the canal.

Q: Would you define a diver tender? What is he?

Chief Badders: He's the man that dresses the diver and tends his lifeline and air hose while he's on the bottom, takes care of his equipment, and assists him by getting the tools to him that he requires, taking care of things topside, watching the air compressor and--if welding machines are used--the welders and all that business.

Q: The diver's Man Friday!

Chief Badders: Right. In other words, a very good candidate for a diver in the future, and that was the reason I had taken the apprentice boys, hoping that they would continue on as tenders and eventually get out of the apprenticeship program and then they would be available for the diving program. But this never happened. These apprentice boys were all subject to draft, and as fast as I could get a group of

them through the school the next thing I knew they'd all be gone on the draft. So it wasn't very long until I saw that that end of the program wasn't going to work at all. I had to get away from the apprentice boy idea and use what we called the local rate people for tenders, the Panamanian laborers. I had a choice of the very best caliber of Panamanian laborers like welder helpers and rigger helpers and carpenter helpers and things of that kind. They were the people I called in.

Q: How did they compare with the others?

Chief Badders: There wasn't any comparison. You can't compare any Panamanian laborer with any American boy who's smart enough to be an apprentice boy in the apprentice program down there. The Panamanian laborer was one of the big headaches as far as I was concerned all the time I was in the Panama Canal, and I guess still is.

Q: You mean they just don't have the qualifications?

Chief Badders: That's right. They're illiterate, to start with, and they have a saturation point. You can teach them just so much, and when you hit that point, you just can't ever beat anything else into their thick skulls. They just can't absorb it. That's all there is to it.

Q: Are they largely of Indian origin?

Chief Badders: Everything, and about 80% of them are illegitimate people to begin with, as you know, the Panamanian general public. Some Indian, some Jamaicans, Colombians, Panamanians. They not only are not as smart, of course, as the American boys, but they wouldn't be dependable in any real emergency, and that's where you need some action, somebody who can think for himself. If a diver got

in really serious trouble all of a sudden, they'd just go all to pieces and couldn't do anything. Some of the American people, divers or anyone who happened to be around the operation on the topside would have to take over and do the job.

Q: I would think, faced with that problem and if the authorities realized it, some sort of protection from the draft could have been obtained?

Chief Badders: They attempted that, but the boys themselves wanted to go, and that's where 80% of my divers went. They'd get through the diving school and go back to their shop. You see, the setup was the men would go through the diving school, and if they successfully completed the course of instruction, they were rated a diver; they had a dual rate. Say a man's a machinist, he'd be a diver and machinist. Well, when he wasn't diving, he'd be working in the shop as a machinist. If I had a job that required a machinist's ability under water, I'd call him out from the machine shop to my organization as a diver. And then immediately he'd go on diving pay until that operation was finished, and he went back to the shop.

But many, many of these people, of course, were young men. They were all under 30, and I don't know how many of them went into the Seabees from down there, and a lot of them made out real well. They became good divers in the Seabee operations. A lot of them just quit diving altogether when they went in the Seabees and operated heavy equipment and became welders and all that kind of thing.

Q: But your operation was equally as vital to the war effort as were the Seabees?

Chief Badders: Right, but you couldn't stop a man if he wanted to go and enlist in the Seabees or something. There was no way to stop him from doing it; away he went, which put me in a bight in this respect. When they said, "Well, we've got to have some divers who can do something and get them quick," I said, "Okay, I've got my curriculum down to six weeks, and I'll put three classes through, 12 men. The first class six weeks, the second class six weeks, the third class six weeks, then I'll call the first

class back for a second six weeks and go on from there and advance them that much more." Well, I never did get the first class back, and I must have run 50 classes through during the war, because they would be dwindled down to where I just wouldn't have them available to come back for advanced training.

Q: That was a pretty discouraging operation!

Chief Badders: Yes! It really put me under a handicap. But these men were exceptionally good men, and we had a lot of underwater construction work in the canal, and these men were doing that work.

Q: What kind of construction?

Chief Badders: Piers and docks and dams, pipelines, and all that kind of thing. They ran three huge pipelines all the way across the isthmus, you know. They could pull a tanker in the Atlantic side and pump oil right into a tanker in the Pacific without putting the ships through the canal. That went through Gatun Lake and part of the canal. That took quite a lot of diving.

We gained experience all the time and were getting better and better. In the meantime, we were having things happen; ships were getting in trouble, by this time. The longer the war went on, the worse the ships became, not only mechanically, but it seemed that the people who were operating the ships--if it hadn't been for the war, they wouldn't have made good able-bodied seamen and they'd be up there as a skipper or chief mate or something operating the ship, and you never knew what was going to happen. We had a lot of groundings. Fortunately, nothing serious happened in the lock chambers. No gates were rammed or anything of that kind because the pilots, of course, had control. But they had control in the reaches and in the lake, too, for that matter, but things would happen--mechanical failures, steering gear failures. A pilot would holler so many degrees right rudder and he'd get twice that many degrees left rudder, and in a canal that narrow you don't have much time to correct that and you ground, and good

and hard, if you're making eight or ten knots. A ship would go aground, and I'd have to get all of my facilities out there and get that thing out. Sometimes it would require partially unloading the ship, sometimes bringing the big dipper dredges out and dredging part of the mud alongside, put tugs on her and pull beach gear, any way to get them afloat, and I if they weren't damaged, well, that would be the end of that. But if the ship had a hole in it from going aground, which some of them did--they didn't only hit soft mud--that had to be patched up, and in some cases it had to be patched well enough to get them into dry dock down there and make permanent repairs. In other cases we made repairs that were strong enough and permanent enough to get them on to their destination, the South Pacific or wherever.

I wouldn't even hazard a guess at how many ships we had aground and damaged. In Culebra Cut they'd hit the bank, and when they hit that they invariably knocked holes in the side. We never had one that was damaged enough that it sank in that area. We were always able to get it into some beaching zone where we could run it aground and it wouldn't sink any deeper, and make repairs to the damage.

We were kept pretty busy. In addition to trying to keep up with my new divers, keep enough diver~ on hand--I never did really have enough--and then doing these jobs when they came up. And that's another thing. When these jobs would come up while I had a class going in school, I'd take everybody right from the school, all the student divers. I'd take them right to that job and use them as much as I could on the job. At least they would be there and see how things were going on, and that period of time would not be considered a part of their six weeks' training because I wouldn't be at the school to handle them during that period anyway.

Q: Did you do all the instructing?

Chief Badders: I had two assistants who took care of some of the instructing, but I did most of it. I was a pretty busy boy, 12 hours a day, seven days a week down there for about two and a half years.

Q: What kind of administrative staff did you have to back you up?

Chief Badders: I had my own secretaries and timekeepers and whatnot. Then my big bookkeeping expenditures of funds and all that kind of business went through what we called at that time the mechanical division offices down there. They just took my budget and my program and all my big letter-writing and things of that kind went through their office. That was the division that had shipyards, the mechanical division of the shipyards, a big yard on the Pacific and one on the Atlantic side. The offices at the Atlantic end did most of my work, and I came directly under the Navy captain who was in charge of the mechanical division. We called him mechanical division superintendent. During the war it was old Captain Kiernan, a fine old man, an old MIT graduate.<sup>49</sup>

Q: On average, how many ships went through the canal a day?

Chief Badders: It varied. To hit an average I wouldn't even hazard a guess. You see, what would happen was they'd come in there in convoys, and if they were coming from the Atlantic and going to the Pacific they would bring in maybe 50 ships in a convoy. Then they would refuel, resupply, whatever they needed in that area to get everything all set for the final run on to the South Pacific, and then they would run them through just one right after the other till they got them all through. Actually, they're putting more ships through the Panama Canal right now than we ever did in World War II, percentagewise today more tonnage, more numbers of ships. They have modernized the handling procedures and all that.

---

<sup>49</sup> Captain James E. Kiernan, USN, Massachusetts Institute of Technology class of 1922.

Q: Did you have any problem with the super-sized ships?

Chief Badders: We didn't have the super-sized ships then. The biggest tanker we had, about the biggest, was the T2 tanker.<sup>50</sup> We had some large carriers, and the large carriers and the large battleships were our biggest problem going through the canal, that is sizewise. But we rarely had any kind of a problem with them other than the tight squeeze in the locks and so on. One did some damage to the bow. I think they scraped the bank in Culebra Cut a bit and just wrinkled up some plates and caused some slight leaks. We had to do a lot of welding on it, welding up small cracks and things of that kind.

Q: The Queen Elizabeth also went through, didn't she?

.

Chief Badders: Yes, that was one of the big ones.

Our biggest headache was the old Liberty ships, Victory ships, and things of that kind. Darn those things, you never knew when one of them was going to break in two on you, and they seemed to have the most helter-skelter crews of any bunch of people I ever ran into. Then, of course, we had our foreign flags going through there, too, that caused us a lot of trouble. The English ships going through there.

Q: Why would they cause special trouble?

Chief Badders: They weren't special trouble, but when we had trouble with them it was generally real trouble. They would have some kind of mechanical failure. Their equipment was in such deplorable condition, they couldn't depend on it at all. They'd try to drop an anchor, and the anchor engine wouldn't work. Couldn't even drop an anchor on a ship one time, which meant that he just kept going, and before

---

<sup>50</sup> A T2 tanker was approximately 500 feet long with a beam of about 70 feet and draft of 40 feet.

they could get the power they required and reverse, why, they barreled into the back end of the ship in front of them.

We had one Liberty ship--we had one convoy coming in the Atlantic end of the canal that was so large they didn't have enough pilots to put a pilot on every ship, so they put a pilot on every other ship, and the one in the middle that didn't have a pilot was supposed to watch the man in front of him and the man behind him and guide him in. Well, there came up one of the worst rainstorms that we'd had in years down there and, of course, the one in the middle just couldn't see the man in front of him at all--period. He couldn't even see the bow of his ship, and he got completely out of line and ran aground outside the breakwater. He went into Cristobal Harbor, and he ran aground good and hard on the rocks. The ship lay there and broke in two.

Q: These were filled with supplies, were they?

Chief Badders: Yes. This particular ship was loaded with drums of asphalt for runways and personnel carriers and jeeps, hundreds of them on the darned thing. We unloaded all the personnel carriers, jeeps, and things of that kind we could get off that were worth saving, put them in barges, and that's the last I ever saw of them. They went somewhere. And then we blasted the bow' section apart and sank it in the mud. They always broke right forward of the forward fireroom bulkhead, and the after section was watertight. So I ordered it flooded to keep it from going farther aground, but once we pumped that out, the water that I had put in her to keep her stable, it wasn't much of a pull to get the stern section off the rocks. And we took that way outside in deep water and set a mine off in the bottom of her and sank it.

Q: What was the cause of this weakness that made the ships break in two?

Chief Badders: Some construction design that wasn't figured out, I guess, when they built them. I don't know, but that was the weak part of all that type ship.

Q: Was it reflected in the attitude of the crews?

Chief Badders: Yes, it was. For instance, this one that ran aground, when this thing started to break apart--it was so rough we couldn't get boats out to get the crew off, that is, with any kind of safety at all. You were taking a chance on sinking your boats and maybe losing the boat crew or something. So we left the men on board. Nothing can happen to them. The thing's aground, nothing else can happen although it's breaking in two and it's popping. If you ever hear a ship break in two, the plates breaking, it sounds like guns going off, you know. This thing was making a terrific noise and working, and the crew went nuts. They wanted to get off that ship, and they kept screaming and hollering that we were--it was close enough to the beach that you could hear them through bullhorns. So to calm their nerves and try to do something, the admiral was on the scene by this time, the commandant of the 15th Naval District, and was advising we've got to do something, we've got men out there.

I said, "Well, we can't get a boat out there with any safety. Those people are just crazy, but nothing can really happen to them. Even if the ship fell over on its side, they'd still be above water. They're high and dry. It's not bad."

And he said, "Can you rig a highline or something out there and bring them ashore on a breeches buoy?"

I said, "Well, it can be done." I had highline equipment, but how are you going to get a line out there? I made them bring a target-towing plane out, towing this target sleeve, and they dropped the sleeve over on the beach and when they crossed over the ship, dropped the wire off the plane like they drop these things on runways. The wire landed across the deck of the ship and the sleeve was ashore. Well, the minute I got that little old stinking wire from that ship to shore, those people calmed down. They knew then there's something over here and from that we'll get something else. And we never did

put a breeches buoy out to get them off. They began to calm down; we could see that they were quieting down and weren't making so many demands for rescue.

The next morning, at daybreak, it had calmed down enough so we could get boats out from shore. Then some of them didn't come ashore; they stayed aboard for a day or two. But they really wanted to get off of that ship! They didn't know for sure what was happening. That's what it was. It was making so much noise in the dark, pouring down rain, just sheets of rain, and here this terrific tearing and ripping of steel plates, and they just, thought that ship was disintegrating right under them, working, you know, on the rocks.

Q: They were panicked!

Chief Badders: Right. They were just panicked. There were a few there that weren't panicking, but there weren't enough in that group to keep the others under control and convince them that they were in good shape. That was one of my most interesting experiences. It lasted about three days before we could even do anything. Then in the meantime a little old smart-alecky Coast Guard outfit came around there and he was going to go in and get these men off, and he ran aground and ran inboard of this Victory--this was a Victory, not a Liberty--where he'd be in the calm and then he'd run high and dry on the same rocks and his ship was a total loss.

Q: Was it a cutter?

Chief Badders: No, it was a little old vessel of some kind that the Coast Guard had taken over from some company--a little old steam-driven thing, a little bigger than a seagoing tug, with about 35 men aboard in the crew. A young lieutenant (j.g.) was the commanding officer. That thing rolled right over on its side. But they came ashore. They got off of there. They launched life rafts and came ashore in life rafts. Then, besides the Victory ship, we have him and it's a total loss.

I had some of my most interesting experiences in the canal after the war. By the time the war was over, I had my men--the ones that were really interested in staying there--were by this time becoming exceptionally good divers and salvage men.

Q: How many did you have at that point?

Chief Badders: When the war was over, I had about 15, and that was adequate for the peacetime operation. About 15 divers, and I guess that's what they're trying to keep on hand now.

Q: But not really adequate for wartime?

Chief Badders: Not war, no. Fortunately we didn't have any big major accident during the war. I mean we didn't have a ship come in there loaded with explosives and blow up and plug the canal, and nobody knocked a gate out of one of the locks or anything of that kind that would have really caused 24 hours a day diving, day after day, until the job was completed. I wouldn't have had enough divers for that big a job.

Q: Does this say something about the effectiveness of security control?

Chief Badders: Right.

Q: Tell me about that.

Chief Badders: The thing about that, we were set up with a tie-in with the Navy that if we had a real disaster, of course the Navy would move right in and help us, bring their equipment and personnel, which was a relief. But the Navy, wonderful men, know all about salvage and diving and all that, but

they didn't know all the answers in the Panama Canal like the men would have that I would have trained right on the scene. So it remained preferable to have had enough men of my own, trained there, local men, trained on the job to do the job that we anticipated might happen, but it never did, not big.

Q: Would you talk a little about the security measures which the authorities took during wartime to protect the canal from sabotage? ,

Chief Badders: One thing, every ship that went through the canal a crew of military people went aboard. Two Marines on the bridge and two machinist's mates in the engine room. One Marine on the bridge, when the pilot would ask for a signal to the engine room for a change of speed, handled the annunciator--the Marine handled the annunciator, the other Marine would write the bells down in a book. And the machinist's mates down in the engine room would see that those bells were answered properly and at the right time.

As I said before, we had had occasions when the pilot would ask for 10 degrees right rudder and he'd get 20 degrees left rudder. He'd ask for full ahead and get two-thirds astern or something. So with these people aboard that couldn't happen.

Then they had other men aboard--just how many I don't know, but they had a few Marines and a few Navy people aboard every ship that went through the canal. They would board at the pilothouse. They put a huge big barge, really a boathouse, before the entrances to the canal, and the pilots and these crews would be on these barges when the ships came by. And when the pilot went aboard, the designated number of men--military people--would go aboard, too. The number of military people varied according to the size of the ship and in some cases what the ship was loaded with. Lots of ammunition ships went through there, of course.

Q: And the military people would inspect the ship?

Chief Badders: Right. They would watch everything as closely as they could and, as I said, fortunately we really didn't have anything, any big sabotage, happen.

Q: Was neutral shipping barred from the use of the canal during the war?

(: Chief Badders: No, neutral shipping went through. All of our allies' shipping went through. We had no problems with any of them. They did some experimenting with a net thing--they called it the "billion-dollar folly." They devised a net, a big steel net, and when a ship went into a lock chamber, this net, which was on floats, came up under the ship, and if anything fell from the ship this net would catch it, and bells would ring, lights would flash, and all that kind of thing, and they'd rush this net out. . . .

Q: And recover the loot!

Chief Badders: ...Recover the loot. A beer can or anything else would set off the alarm. It didn't work out. It was abandoned. It looked beautiful on paper, but it was cumbersome and hard to handle, held up the ships. That didn't work. That was done away with. t

Q: What about the question of fees, which are charged ordinarily in peacetime? In wartime what happened?

Chief Badders: I don't know. That is a phase of the Panama Canal that I never got the least bit interested in. I do know that fees today are almost the same as they were even before World War II, way before World War II. They haven't changed the fee rate in years and years in the canal. And it should have been increased a long time ago, but the shipping lobbyists are just too strong. Every time it comes up for a vote to increase the toll, as we called it down there, why, the shipping lobbyists would go to work and stop it.

Q: During wartime was there any real danger of sabotage from the local populace, or from agents working among the local people?

Chief Badders: It was known that there were agents in the area. In fact some were arrested. That was another part of my work down there. I was kind of assistant intelligence man to keep my eye on people and things, but they were never able to penetrate the defense and do anything down there that we knew of--at least, not that I knew of and I think I would have known if anything happened. They had cases of radio operators. They raided one place and found a complete radio installation where a man was relaying the information on the ships coming through the canal, what was aboard, and what ship size, even the name of the ship. They stopped that. A few things of that kind, but they never got around to where they could plant a charge anywhere and blow up anything.

Q: How well guarded was the canal?

Chief Badders: It was guarded as well as it could be. They had all kinds of military defenses around the canal. They had barrage balloons at all the lock areas, and searchlights, radio, all that business, and, of course, antiaircraft guns. We were a long time getting this stuff. The war had been going on quite a while before we had any antiaircraft guns down there. They figured it was important in other places, I guess, before we got it. They had thousands of military people and we had our air stations there, the submarine patrol, and all that business was operating all the time.

Q: Did they ultimately have radar also?

Chief Badders: Oh, yes, they had radar stations for spotting. It's a pretty complex place to defend really. Of course, now things on the site of the Panama Canal are practically useless. That's why they're pulling a lot of the military people out of there. They figure they've got to be 1,000 miles away to do any good protecting the canal now with bombs and stuff and missiles they can fly in. One big worry with

the canal was--you know Gatun Lake is held in place with a dam, and without Gatun Lake there is no Panama Canal. And that dam has a spillway in it for spilling the excess water, and there was always a fear that something might knock part of that spillway up and spill the water out of the Gatun Lake, and that would close the canal up until the spillway was repaired and the lake built up again. They built an underwater dam--well, I guess you could call it a dam; they called it a spillway. In other words, where this spillway was, there are 14 gates in the spillway that can be opened. Well, they built another spillway in front of that, all underwater, and bombproofed it. That was another diving job that we did there, and that was one of the jobs that held my diving school up because I was used on that job until it was completed.

The point of this thing was if they knocked the old spillway out--all the gates and everything were above water--this underwater spillway could be closed up by dropping gates in the steel structure that we left there and still hold the majority of the water in the Gatun Lake.

Q: It was a supplementary dam there?

Chief Badders: Right. But fortunately, there again, we never had to use the thing, but it was there if anything had happened. And many things could have happened. We had several alarms. People said one time that there was a raft of dynamite floating toward Gatun spillway. Of course, they had a power plant at this spillway, and it created a little current running in that direction all the time. Someone said they'd seen a raft floating toward the spillway and it'd be over there in another half-hour or so and blow that thing up. Well, that alerted everybody, all the lights and boats, but no raft was ever found.

Q: What was the attitude of the Panamanian Government and authorities at that time? Did they put obstacles in the way of the operations, the smooth working of the canal?

Chief Badders: No, no. During the war they were very cooperative, as far as I know. I never heard of anything of any magnitude. Of course, by this time they were beginning to get money-hungry and seeing where they can get rich quick. They cut in on everything they could money-wise, but they didn't hamper the canal operation in any way. There was no way they could really. They couldn't even furnish the people we needed for laborers on the canal. We recruited people by the thousands from Colombia, Costa Rica, even some from Puerto Rico, but most of them were from Colombia, Venezuela, and all around that area. They worked on these new construction jobs and extra men in the shipyards.

We had a very busy shipyard situation there. Ships coming in there to go on to the Pacific or coming the other way going back to the Atlantic Force, by the time they'd hit there they'd need repair work of different kinds. We had a big bottom-cleaning program in the Balboa shop area. Big tankers would come in there if they'd been to sea long enough and were fouled up on the bottom and, of course, foul bottoms slow you down and require more power. They worked out a program where some of them stopped off there to get their bottoms cleaned. That required a lot of men because this had to be done quickly. That's when they first started using hot plastic paint on ships bottoms, down there at least.

Q: Protects them from the barnacles.

Chief Badders: Right, take the barnacles and the sea growth off.

Q: I suppose there were examples of ships that were damaged by submarine activities in the Caribbean and thereabouts that had to come in there for emergency repairs?

Chief Badders: Right. We had one tanker--you could see it from the breakwater--that was torpedoed by a German submarine right close to our area, and he hit it on one side and knocked a tremendous hole in it. The ship rolled over on its side and the crew abandoned ship. The submarine surfaced to periscope depth and saw that he hadn't sunk the ship. Then he went around to the other side and fired another torpedo

which hit right opposite where the first one hit, knocked a big hole in that side, and the ship rolled over back on an even keel and sat there, didn't sink. By this time we've got our patrol planes out, dropping depth charges and things, and the submarine took off.

Then, after they'd watched the thing for quite a while and seen that she wasn't going to sink, the crew went back aboard and brought it in closer to the breakwater. I took divers out and when they saw how much damage was done, it was safe to bring the ship through the canal. The first diver that went down and came back up said, "My God, the only thing holding that ship together, the two ends of it, is tank tops and the deck. If it didn't have a mast on it, you could drive a destroyer right through the ship." So I made my report and said that ship was liable to break in two at any minute.

There it's sitting and they looked at it--all this damage was below water--and it's sitting there looking pretty good. It had sunk some in the water, I think the draft had increased about 10 feet or something like that, which is nothing in a tanker. They determined they were going to take her through the canal to the Balboa dry dock. The dry dock in Cristobal wasn't large enough to take it. They took it over and put her in and they had lots of tugs and handled it very carefully, and when they pumped the water down and saw how much damage really was done to it, the port captain in Cristobal who had ordered this operation to proceed almost fainted. He said, "If I'd realized that ship was that nearly broken in two, it would never have gone through the Panama Canal."

We had another one come in there, and he was supposed to wait in an area for a pilot, but he didn't wait; he kept creeping on in. He got out of the channel and of course outside of this place was mined and he got over in the minefield. These mines were, some of them, contact mines and some of them could be exploded with a paddle over at Fort Sherman, and this mine officer sitting there watching this ship, going over in the minefield, and he sent a recognition signal to him and this fellow didn't answer anything. He didn't know any recognition signals--he was a Czechoslovakian, I believe. So the only thing for the mine officer to do was push the button on a mine right under him and blow him right out of the water. It raised his stern up and gave him a start, and he slid right straight across the channel

with his stern sticking out about 50 feet right into the channel coming into Cristobal. He had a deckload of antiaircraft guns. We had to go out and get the antiaircraft guns and then with explosives get rid of the stern of that thing just sticking out in our channel.

Q: Those minefields were to prevent the submarines?

Chief Badders: Yes, or anything else.

By the way, we lost one of our submarines down there on the Pacific side, going out on patrol duty at night. The channel going through the minefield on the Pacific side was changed every so often and only a few people would know this channel where it would run through. Things had to be escorted through there. We had some cutters and things, and we had a great big yacht that the Navy had taken over and it was a so-called escort vessel, and that was its duty to escort people through the minefield. The commanding officer of this cutter would be informed of the route through the minefield.

Well, he had escorted these three S-type submarines through the minefield and when they get through the field, then he would cut off and come back in and they would go ahead. Of course, everything was blackened out. And when he cut off either he or the submarine, it was never determined, made a mistake and he rammed the sub and sank it, one of our submarines in about 320 feet of water.<sup>51</sup> I guess two or three men survived.

Q: Was there any danger from German raiders?

Chief Badders: They thought there was. They were prepared for that. You mean air or water?

---

<sup>51</sup> On the night of 24 January 1942, the USS S-26 (SS-131) was rammed by the PC-460 and sank in the Gulf of Panama. Of the crew, 46 men were lost and three survived.

Q: Water, raider ships.

Chief Badders: Well, no, they were more concerned with submarines than anything else. The submarines must have come in there awfully close, because we had a ship coming through the channel, right at the entrance to the breakwater, and it got something in its propeller and stopped the engines right there, just like it had hit a solid rock. Well, it drifted on in and they got tugs round it and brought it in to the dock, and sent for divers to go down and see what had happened to that propeller. I didn't have any diver available right at the time on the Atlantic side and this was a big hurry-up thing, so I got in gear and jumped down myself. When I got down there, it looked to me like a big hot-water tank or something had been picked up. It was a tank about 30 inches in diameter and about 6 or 8 feet long, and this thing had got crossways on the skeg, and the blade had hit it and just wrinkled it up around the tip of the blade, and the blade was right up and down over the skeg, and that's when it stopped.

I looked this thing over really well, and I looked up on one end of it and here's a round brass plate on it that had some kind of foreign language on it that I couldn't read. So I got out of there and came back up, and I sent for the mine officer or one of the mine officers over at Fort Sherman. By this time I suspected it might be a mine. I explained this whole thing to him, and he asked me to go down again, and take a better look at that plate and make out this lettering and bring it back to him, which I did. He said, "Well, it's a German mine," and he explained the type and everything else. Well, why didn't it go off, or what are we going to do to it from going off?

He said, "Well, that handhold plate that you see that had about 20 brass flat-head screws in it. Take them out and then you can pull that plate out and that will pull the detonator out. But you'll have to be careful when you do it."

So, when that operation got set up--we're not going to do that operation alongside the dock--the crew left the ship. They towed the ship out in the explosive area, and I took one tender with me and went down and took the screws out of this plate and started to bring it up.

Q: You did that job yourself?

Chief Badders: Yes. I moved the thing about 6 inches, and it wouldn't come any farther, got jammed.

Well, I'm not going to force it--he told me not to put any force on it and be careful it doesn't hit the sides when it comes out--he explained it to me it was a thing about so long.

Well, I came back out and explained all this to him. I'd get him to come out and backed the boat away from this thing a couple of hundred yards before he can come out. I talked to him and he said, "Well, that detonator is down in there so far that that kink in the housing of the mine has got it jammed and you can't get it out."

This was an ammunition ship loaded with ammunition. Well, they want to get this out, they want to get the ammunition to its destination. They didn't want to unload it and transfer it to another ship. That would take days and days to do that down there. So I said I'd try one thing. I took a big long section of another chain and took a loop around that blade that was over the tank, the mine--by this time we're calling it a mine; we're not calling it a tank any longer. And I got one of our biggest tugs there and put two tow wires, his tow wire and another one, which put him a couple of thousand yards away from the ship, hooked up to the chain and he was right abeam of this thing. I made him back up to where he had a lot of slack in the wire and then go ahead just as hard as he could go, full speed, and jerk that blade to see if he couldn't jerk it back the way it went in. And, sure enough, it came clear, and it didn't explode.

Of course, I'm back out of the way of that operation when that happened; there was nothing near the ship.

Q: You'd think the jolt would have. ..

Chief Badders: The blade wasn't damaged enough to prevent the ship from going ahead, so it was only held up about a day with a German mine it picked up right in the entrance of the Cristobal breakwater. Whether that thing had been somewhere and floated in there, or whether it had been planted somewhere close to that area or dropped off. . . .

Q: Was that area swept with great regularity?

Chief Badders: Oh, yes, we had torpedo nets out there all the time, harbor nets, you know, and they had to be opened for every ship that went through and closed all the time, and boats ran back and forth with sounding equipment. But they didn't go outside the breakwater very often. I think they did after that. I think they began patrolling farther out at sea.

I had heard reports of Navy planes spotting submarines out there, outside our minefields, and dropped depth charges down to run them off. There was no record of any of them ever being sunk or captured out there, but they did claim sightings.

Q: What about the other side, the Balboa side?

Chief Badders: We never had any problems over there.

Q: Wasn't there always the fear that the Japs might come along?

Chief Badders: Well, we were standing around there with our hair standing straight up on our heads after Pearl Harbor. We just couldn't understand why they didn't come on and do the same thing to the Panama Canal. Then, of course, we found out later that they didn't want to damage the canal; they wanted to use

it themselves. That was the only reason they didn't. 'There wasn't a thing in the world to keep them from coming on and just blowing the Panama Canal right out of existence.

Q: I didn't know that story, that they wanted to use it.

Chief Badders: Sure, they didn't want to damage the canal, or they could have come ahead from Pearl Harbor. We didn't have enough Navy left then to stop them. We didn't know what was going to happen around there for a while, after Pearl Harbor.

Q: At one time there were some vague ideas that we might do something about fortifying the Galapagos and islands in that area.

Chief Badders: Yes, we had a lot of people out there. I went out there twice working on underwater pipelines and cables. It was sounding stuff, radar signal relay, and that kind of stuff. There wasn't much of a defense out there, but there were quite a few military people on that barren rock. What a place to do duty! Miles and miles from nowhere.

Q: Those must have been exciting days for you and strenuous ones, as you say.

Chief Badders: Yes, the days just weren't long enough, and there weren't enough of them to keep up with things that were going on; that was the trouble. I worked myself right down to a nub.

Q: You didn't have much family life?

Chief Badders: Very little. My wife would see me sometimes like today and I'd go off on jobs and when I went on a job I just had to stay until the job was finished. A lot of times I'd work as many as four days and nights without ever stopping. Then there were many jobs where I'd be out a week or two on the job. Of course, there would be rest periods at that time. But I've been on jobs that were in such a stage that I just didn't even stop.

That was one of the problems with my job down there. I should have had another man at least in my capacity, somebody who could relieve me.

I was on one job, and this was after the war, too. I'd been on the job four days and five nights, brought the ship back into the dock in the explosive area in the morning and my boss by this time is the marine superintendent, a Navy captain. He saw me and said, "When were you home last?" I had on a pair of khaki shorts and an old what had been white sweatshirt and a golf cap and a pair of sneakers. I was filthy dirty and I guess my eyes must have looked like burnt holes in a blanket. I said, "I haven't been home since we took the ship out to the explosive area." I'd lost all track of time. After you've been up a certain length of time, you don't get sleepy anymore. You lose track of everything.

Q: But you're not quite as sharp as you were!

Chief Badders: That's the point, exactly. You can hurt yourself or hurt somebody else by not being as alert as you should be. Well, he sent me home, and right then was the crucial point of this operation. The ship had been on fire alongside the dock. They thought they had the fire out--they did have the fire out--a chemist and other people were going through the ship looking for gas and explosive areas before they could let people do different types of work, and they were down in the refrigerating section of the ship and went into the refrigerator part of the cold storage. There was no gas in there, but they opened a door

to go into the freezer section of the refrigerator compartment, and somebody must have struck a match right at that time or was smoking a cigarette or something, and that thing was full of explosive gas and it blew up and killed three men and maimed four or five others--a big thing about it.

So immediately this ship was grabbed and rushed out of there, taken to the explosive area, and that's when I went aboard. It had a lot of soybeans aboard, and we found out right then--it may have been known before, but I didn't know it and no one I talked to down there did--soybeans soaked in salt water put out 100% explosive gas. These soybeans were swelling up like popcorn. A soybean is not too big, but when that thing is soaked in salt water it's six to eight times its normal size. Several of the cargo holds of this ship were full of these bulk soybeans, and they were swelling up and throwing off this gas. I had to get rid of the beans.

Q: Did you get a special citation for all of this tremendous work?

Chief Badders: No, I have a folder full of letters of commendation. It was my job. That was what I was hired for.

I say "I" had to get rid of these beans, but I must have had 15 or 20 men working with me on that job. We moved those things with airlifts. They wouldn't let us use any kind of metallic equipment like shovels. Normally, to unload something like that you bring a crane alongside with a big scoop. . . .

Q: Why? Because of the friction?

Chief Badders: Yes, they're afraid that a clamshell might hit a hatch railing or something and make a spark and blow this thing up. We opened one of the hatch covers and this water would start working on these beans, and they'd swell up and run out over that hatch foaming just like popping popcorn. The darnedest thing I ever saw. I pumped I don't know how many hundred tons of soybeans right over the side in the Pacific.

After this operation had been going on for a couple of days, then the wildlife people got interested: "What's this going to do to the fish?" That's the greatest fishing country in the world down

there. We found out that the fish just got good and fat on it. They loved it. When we first dumped some of these over, they would sink to the bottom and then a day or two later they'd all come back up to the surface again. They were lying on the water out there it looked for miles, like an oil slick really.

Q: Did they discover any use for this gas produced by soybeans?

Chief Badders: No. Actually, I don't believe the gas was as bad as they said it was. I don't believe it was that gas that blew up. In fact, I know it wasn't that gas that blew up in this freezer compartment, because there was no way for it to get in there. I think the gas in there--well, I don't have any idea what kind of gas it was and nobody else did find out, because when it exploded the gas all deteriorated and there was no way of getting a sample of it. A couple of my good friends were hurt badly on that job. The chemist was killed.

In navy yard routine, when a ship is damaged, any work is going on on the ship that's in closed compartments or compartments that have been closed, and particularly a damaged ship, the chemist has to completely analyze the ship for gases and all that stuff. The chemist should have just been doubly sure that the people behind him were not smoking or getting ready to smoke or anything. Evidently he hadn't checked as well as he should. Of course, it's possible that something else could have set this off when he opened the door, but they couldn't think of anything else that would do it. Two or three men who survived in this work party said they thought they had seen a match struck or a cigarette lighter lit just before the explosion. They couldn't be positive.

But we had to unload this ship out in this explosive area. Then the operation of going around and trying to detect where this gas came from. You could smell this gas coming from the beans. They took a sample of that, and the chemist got all excited. The report was that it was 100% explosive, and it had to be unloaded before the ship could come back alongside the dock--that is, all the beans that were wet or liable to get wet.

That was the operation I worked on so long without stopping, because we were way out and it took a long time to get set up and get in and out, so I just stayed there.

I made a lot of trips from the Panama Canal to other countries down there. The canal would loan me to other countries for jobs. I went to Nicaragua and did a job for old President Somoza, the one who was assassinated, not the young son who's dictator down there now, but the original old Somoza that the United States put in power when there was trouble in Nicaragua.<sup>52</sup>

We had a yacht on that lake down there, Lake Managua, and another tugboat. They were the only two vessels in the lake and they came together and sunk his yacht, and he wanted his yacht raised.

Q: This was during the war?

Chief Badders: Right after. I worked with him for about six weeks, I guess I was down there, to raise his yacht.

Q: Did they treat you well while you were down there?

Chief Badders: Very well. I thought I was eating like a king. We lived right on this other tugboat that had sunk his yacht. We were working from that, and a big banana barge, and he was living right there on the job. All the food that came aboard, anything like fish, any fowl, even pigs, were brought aboard alive. All water came aboard in locked cans, drinking water. Milk was in locked cans. The food was, I thought, out of this world, and it was. But one day I happened to be down below around the galley and I

---

<sup>52</sup> Anastasio Somoza (1896-1956), president of Nicaragua from 1937 to 1947. His son, General Anastasio Somoza Debayle (1925- 1980) was president from 1967 until his overthrow by Sandinista rebels in 1979).

saw one of the cooks come out-this tugboat had only about 2 feet of freeboard, he could reach over the side and dip water out of the lake in this bucket, and this was right aft of one of the head discharges where the water was running right aft on the ship and he must have got some of that discharge into his bucket. I watched what he was going to do with it and he went in the galley and dumped it in the sink and that's what he was washing dishes in! Well, right then I got sick. I couldn't eat anything on that ship anymore, and I had about two weeks to go yet! I had all kinds of stomach problems from then on. The only thing I ate was bread and stuff like that, jelly, cheese, goat cheese. I ate goat cheese three times a day, and guava jelly. I just about lived on that the last two or three weeks I was there.

When we got ready to leave, he gave us all a present. I had a Navy commander with me who was kind of a liaison officer. The Navy really engineered this deal. It was one of those lend-lease things, you know, us and the equipment, and we took this Navy commander along as a liaison man between him, me, and the commandant of the 15th Naval District. By this time, we'd gotten really well acquainted with old man Somoza--he was a character--and he said, I'm going to give the commander a medal. I can't decorate you fellows. [I had two divers with me and a couple or three colored fellows as diver tenders.] I can't give you fellows medals, you're civilians, so I'll have my aide decorate you when we get into Managua." And he gave each of us a dozen handkerchiefs, myself and my two divers, that he said he had specially handmade. I believe my wife must still have them around here--the most beautiful things you've ever seen--handmade lace handkerchiefs.

We didn't know how we were going to be decorated when we got into Managua, but we were going to have to lay there for a day or two before a plane came in to take us back to Panama.

Q: That's a dull place!

Chief Badders: Yes. We went in by train and when we got there a Nicaraguan Army captain--I guess he was Army--met us and took us to the hotel and he told the hotel manager when we went in to register

that everything we wanted--it didn't make any difference what it was we ordered--went on the bill to be sent to the President. Then he handed each one of us an envelope and said, "This is from the President," and in the envelope were three \$100 bills, brand-new \$100 bills. That was our decoration!

He was quite a man. I talked with him a lot on that job, and I got to really like him. You know, he was considered to be a dictator in that country, making millions off of the country and off of the people, but he told me and I believe he was right, that he only did things for the good of his country, and he had built schools, he'd built roads, he'd built hospitals. He said, "I go up here in the mountains and I find a stand of mahogany [and they had beautiful mahogany in Nicaragua.] I try to get people interested in going up there to get that mahogany out of there and sell it, make money for the country and for themselves, too. Nobody's interested. They won't do it. So I go do it. I put men up there. I might use some of my road equipment trucks to haul it out and things of that kind, but I'm putting men to work. I'm making money and there's money going in the treasury."

I really think they assassinated the wrong man when they shot him. That son of his who took over when he left, he was a stinker. He was a West Point graduate, too, his son.<sup>53</sup>

Q: Was he? He's not so much for the people as for himself.

Chief Badders: No. He's arrogant, overbearing. At the time this happened, our commercial air terminal was in the Canal Zone, they flew out of Albrook Field--they hadn't built the big Tocumen Airport out in Panama yet--and he'd been in Panama for something and he had to go down to the airport to catch a plane and go back to Nicaragua. And he came in the lobby of that terminal with double holsters and a big pearl-handled revolver in each holster--in the Canal Zone to catch a plane to go to Nicaragua. They

---

<sup>53</sup> General Somoza graduated in the West Point class of 1946.

had a big hassle over that, trying to get him to get rid of the guns. This was shortly after he had relieved his father.

When the old man was shot, they brought him to the Canal Zone. He was in the Canal Zone hospital when he died. He always wore a scarf round his neck and he had a ring that he'd slip up over the two ends of the scarf to hold it together up under his chin, and that thing must have had a ten-carat diamond in it. It looked like a headlight hanging under his chin. I told him one day, "You're going to lose that ring off that scarf. It's going to slip off and drop overboard or something, and you're going to lose it." But he was still wearing it when I left him. We used to go to all those countries down there. All the oil companies had offshore oil lines where they didn't have piers to bring their tankers in and unload. The tankers would pick up the hose at the end of the pipeline and pump the oil ashore. They were invariably having trouble with them. They'd slip in their moorings and break their hoses, or their pipes would get holes in them, deteriorate, and send divers. In some cases I went with them.

I went to where they were building the transamerican highway, building a bridge across one of the rivers, and they had some caisson trouble. I helped them out with that.

Q: That must have been in Guatemala, wasn't it?

Chief Badders: No. It was San Jose, Costa Rica.

So, all in all, the Panama Canal job was really an interesting job. When the war was over, I figured that I didn't know what was going to happen. That was one thing that I was a little perturbed about, but they left me on inactive duty all during the war down there with civilian status. I went down there as a chief petty officer and had been since 1926. I was a senior master diver in the Navy and had had experience in salvaging three submarines, and I figured that I was the leading man in the enlisted ranks in that type of work. They must have figured that, too, or they wouldn't have sent me down there.

They'd have sent me somewhere else. Well, I felt that after the war hit and I'd look around and see all the shipmates of mine going up to lieutenant and lieutenant commander, commander, and whatnot, if I'd been on active duty I'd have had that same opportunity.

Q: Naturally!

Chief Badders: Which I didn't have on inactive duty. I couldn't get advanced.

Then when the war's over, here I am still a chief petty officer, civilian. Panama Canal have decided by this time that they want this installation of mine to be a permanent part of the Panama Canal for future protection of the canal, to assist shipping and all that. They told me that they were going to keep the diving school and everything as it was--cut down on some of the equipment and some of the personnel--but to keep a force for me to figure out what was required for a force for ship repairs and construction work that might come up in peacetime operations. And they said that they would like for me to stay on the job. So I told them I would stay if they would make it Civil Service which all the employment in the Panama Canal is, so I dated back to the time I went there in March of 1940, and they did.

Q: You had some sort of tenure?

Chief Badders: Right. When I finally retired from there, I had 23 years' service in the canal and 22-1/2 years in the Navy--45 years and some months' government service. But I would have loved to have had the opportunity at least to have a commission at some time. I'm sure I would have had it.

Q: Did you make any effort to do this after the war?

Chief Badders: Nothing could be done after the war. I wasn't the only one in that situation.

Q: Your high-placed friends in the Navy might have helped you.

Chief Badders: There were attempts to do it. McNamara, even was interested at one time.<sup>54</sup> He said, "Well, it wasn't right. I don't see why we couldn't make a paper commission anyway." When I retired I combined my Navy service with my civil service. In other words, I take one paycheck instead of two. I would have taken a Navy check and a Civil Service check, or you can combine military with Civil Service and take one.

Q: That's more pleasing to the comptroller to make one!

Chief Badders: Not only that, but it increased my Civil Service time and gave me much more money than I would--not much more, but some. So if they were to give me a commission even now it would only be paper, it wouldn't be money-wise, but it would have given me the privileges and the social standing. Down there I was considered one of the big wheels, or whatever, in the canal and we went everywhere. We were accepted everyplace, in admirals' quarters, at admirals' parties, and the governor's parties, and everything else. But then every once in a while we'd be around some officers' club at a cocktail party or something--my wife never told me about this, but I know it happened--some officer's wife would ask her, "What's your husband's rank?" Well, she wouldn't think and tell them I was Civil Service; she'd say chief petty officer. Frost kind of fell after that.

---

<sup>54</sup> Robert S. McNamara, Secretary of Defense from 1961 to 1968.

Q: It does with some people!

Chief Badders: Yes, but to the people that count it didn't make any difference.

Q: Were you tempted at all to live down there permanently?

Chief Badders: Well, you can't live there, except live in Panama and I wouldn't live in Panama--no, I wouldn't even have lived in the Canal Zone. We wanted to get out when we did. We had become kind of tired of the place. It's monotonous, and politics were getting rough. I think we left at a good time.

I would have worked for a few more years. I was healthy, felt good, and I could have done a good job for another four or five years, but to not be working, I wouldn't have stayed there, which I didn't. As soon as my time was up we got out of there. I worked as long as I could. You have to retire down there when you reach 62.

Q: That's considered foreign duty and you have to?

Chief Badders: Right. But it's a shame, because not only me but other people had to go out down there the same way who were perfectly capable of doing a good job for a few years longer, and a lot of them wanted to. I didn't ask to, but I don't believe they would have let me stay anyway.

That's one of the reasons we came to this part of the country to settle down. We got so darned tired of everything being green all year long and warm all year. We like the change of seasons, but I tell you these winters are getting colder for me every winter!

Q: Well, you've got a great career to contemplate, a really great career, and I thank you very much.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF BILL CULPEPPER

Kensington, Maryland

June 30, 2003

## PROCEEDINGS

INTERVIEWER: It's June 30th, 2003. I'm at the home of Bill Culpepper. First, thanks, Bill, for agreeing for the interview. I wonder if you could start off by giving us your background, like where you came from, where you went to school, and how you actually found your way into mine countermeasures.

MR. CULPEPPER: Well, it is, I guess, a relatively short story. I graduated from Pensacola High School in 1946 and entered Auburn University the same year. I took my freshman year, and I was 1-A in the draft, so I decided to get that out of the way. The Army was taking 18-month enlistments, and the GI Bill was still available, so four other guys from Pensacola and I joined the Army. I ended up in Korea for 13 months, but before the Korean Conflict, fortunately. I came back and went back to Auburn. I graduated in 1951, BSME. In March of that year, before I graduated, I had not interviewed with anyone, but the aircraft company, McDonald-Douglass, was hiring any warm body for \$4,000 a year to draw aircraft parts in St. Louis. I decided that was about the best I could do.

Fortunately, I met some people who became very good friends, Margaret and Danny Roberts. As it turned out, Margaret worked at the Navy Mine Countermeasures Station (NCMS) in Panama City, and Danny was the manager of National Airlines. Danny was often a great asset once I began to travel. Margaret asked me where I was going to work, and I told her what I thought. She said, "Well, why don't you come down to Panama City? We hire mechanical engineers." From that, I went to NMCS and interviewed with all the division heads and the technical director.

After that, the personnel officer asked me when I wanted to go to work. I said, "Well, nobody has offered me a job yet." He said, "Oh, yeah. You have a job. Just start whenever you want to come in." I indicated that I would like to take a couple of weeks off after graduation, and I ended up at the Navy Base the last week in June of 1951. I worked primarily in mine and torpedo countermeasures for the first 12 to 13 years that I was at the Navy base, mostly in underwater machine design.

In 1963, I was in the Mechanical/Hydrodynamics Branch of the Engineering Division. My branch head, Ray Kelly, was assigned to a study group for a six month period, and I was acting branch head while he was away. At the end of that period, in January of 1964, shortly after I was relieved from that assignment, I was asked if I would like to design a SeaLab. I said, "What's that?"

At that point, I had never been involved in diving, other than snorkeling and spear fishing, but not having another project to do, I said, "Sure." I was introduced to Captain Bond and a few of the other people, and we started having meetings in January. In February, we got funding and started to design SeaLab I in March. At that point, I think we had \$35,000 in the budget. Bob Port did the electrical and electronics designs, and I did the mechanical life support and structural designs. We did most of our own drawings, and we'd take them to the shops and have the hardware built.

INTERVIEWER: You don't have any idea where those drawings are, do you?

MR. CULPEPPER: Yes. I talked to Steve Segrest after I talked to you, and he assured me that the drawings were probably still there.

INTERVIEWER: Oh, great.

MR. CULPEPPER: While Steve was the head of engineering, he had made it a point to not destroy any of the information that was there, and he was relatively sure that the records would go back to the sixties, at least.

He said that I could get in touch with Fred Doepke, who is the head of engineering now, and he would take me to where the drawings are stored. I plan to go out one day this week and see what we can find. Steve seemed to think that the drawing logs are there, and if I can find the logs, it should be fairly easy because everything was in a window from February until June of 1964. We should be able to find the drawings.

INTERVIEWER: Can you talk a little bit about the design at the SeaLab I, as far as what you were really trying to accomplish?

MR. CULPEPPER: Well, the direction I was given was to design this craft, undersea house, or habitat, as Captain Bond titled it, to house four aquanauts who were to live on the bottom, at a depth of 200 feet, at ambient pressure for a period of two weeks. That was pretty much it. Tom Odum had sold the project based on the fact that we had these minesweeping floats, which were suitable for building the hull, out in the salvage area. They were 9 feet in diameter and 57 feet long. They each had a cylindrical body section, a conical tail, and an ellipsoidal nose section. Hull thickness was half an inch over the upper half and three-quarters of an inch in the lower half. They had been designed to resist the forces of mine explosions. They were adequate to meet the 15 pounds per square inch (psi) design requirement. We were able to cut the tail section off of one and take the nose section off of another and put those together. That made the hull. It was 40 feet long and 9 feet in diameter.

We were pretty much dependent on Captain Bond to keep us on the safe side, as far as what materials that we could use. For example, we didn't want to use any plywood because the

glues might outgas toxic or noxious fumes. We couldn't use anything containing solvents of that nature, certainly no hydrocarbons. It was a very challenging and interesting project, to say the least.

INTERVIEWER: How long a process was it from the time you got the award to actually putting it in the water?

MR. CULPEPPER: It was three months. We delivered it the end of the first week in June.

INTERVIEWER: That's amazing.

MR. CULPEPPER: That included outfitting the surface support vessel, also. On Armed Forces Day, May 16, we had SeaLab I on display for the visitors. It was structurally complete at that point. We were still outfitting the internals.

Much of the equipment that went into SeaLab I was purchased with a Sears credit card. We had a two-burner hotplate. We had a thermo-electric refrigerator that, as it turned out, didn't work because we didn't take into account that the temperature controller was pressure sensitive. It stayed off. It served as a storage compartment, I understand. For heaters, we had Nutone bathroom ceiling heaters, electric. The dehumidifier came from Sears. The water hose was a thing of its own. Commander Roy Lamphear, who was the project officer, selected the garden hose. He would go to Sears, buy a hose, bring it out to the Navy base, fill it with water and let it lay on the pier for a day. Then, he'd go out and sample it to see how it tasted. It took him three or four hoses before he got one that didn't affect the taste of the water.

INTERVIEWER: Was this all pumped down from the surface?

MR. CULPEPPER: Yes.

INTERVIEWER: The water, or the electrical power that pumped the water, was it battery operated?

MR. CULPEPPER: No. It was all surface-supplied, including water, air, helium, electrical, communications, electronic sensor data, and so on. Make up oxygen was stored below the hull in three 1300 cubic foot bottles. Emergency helium was stored in one 1300 cubic foot bottle. The only real background we had for a design reference was a *National Geographic* article written by Jacques Cousteau on his thirty-foot saturation dive. One of the big problems that Cousteau had was with helium leakage through hull penetrations.

Since we didn't have a lot of time or a lot of money, we totally had to take a shotgun approach with most things. One of the things that we came up with was to use an umbilical tube that penetrated through the bottom of the hull and extended well below the entrance hatch. We brought all of the surface supply hoses and cables through that tube, like the electrical, , air, water, gas, and electronics hoses, the whole nine yards.

We also set aside the after nose section, the nose cone section that we welded to the SeaLab hull as an air space. It was separated from the from the living area by a watertight bulkhead. We had the electrical transformers in there, along with several other things, such as circuit breakers and other electrical components that might have caused problems.

The air space had a hatch that was adjacent to the entrance hatch, and it was to serve as an escape chamber in the event that the habitat became contaminated. The aquanauts could exit the living space and climb back up in the air space temporarily, until they could get to the surface transfer capsule down there and bring them up. The umbilical tube worked great, and we had no problem with leakage or loss of helium. Some of these things are a little cloudy. It's been a while.

INTERVIEWER: It was years ago.

MR. CULPEPPER: Yeah. It's approaching forty.

INTERVIEWER: The helium wasn't just a steady flow of fresh gas, though. Were you circulating?

MR. CULPEPPER: Yes. We circulated with the DH machine, made up oxygen and had carbon dioxide scrubbers. We had two submarine auxiliary scrubber units utilizing lithium hydroxide.

INTERVIEWER: Was it lithium hydroxide in there?

MR. CULPEPPER: Yes. We also mixed the breathing gas for the Mark VIII semi-closed circuit SCUBAs. We had high pressure air but nothing to pump oxygen. We couldn't afford a \$6,000 PPI pump. Roy Lamphear said, "Well, let's build a pump, a water ram." I said, "How do you do that?" Well, he explained the principle to me, and I started looking for tanks. I could not find stainless tanks, so I ended up using carbon steel tanks.

We had three vertical tanks that were connected from the bottom of the air side tank to the bottom of the center tank, and from the top of the center tank to the bottom of oxygen tank. Tanks one and two at the air inlet side were filled halfway with water and oxygen or HeO<sub>2</sub> was cascaded into the third, or output, tank. Then, all of the water was forced into tank one, with the gas to be compressed filling tanks two and three. The output side was then valved to the flask to be filled, and HP air was valved into the first tank until all the water was forced into the center tank. The process was repeated as necessary to provide the amount of gas and pressure desired. We were able to find 3000 psi sight gauges, so we could determine where the water levels were. But I was quite concerned about the possibility of rust and fire, especially when jamming oxygen.

As it turned out, Roy Lamphear operated that ram. Nobody else touched it, and it did the job without incident. We were able to get that all together and build it. We even built air filters

with the air piped into the bottom at a peripheral inlet so that the air spun as it went into the filter.

In the upper section, we installed cotton and charcoal.

INTERVIEWER: It was a cyclone that removed water.

MR. CULPEPPER: Yes. We had to put all this stuff together.

INTERVIEWER: It was readily available, but back then, you had to build everything?

MR. CULPEPPER: Yes. I had never had any experience with oxygen cleaning. We ordered some Jamesbury ball valves, and I ordered them oxygen cleaned. Then, when we were pressure testing some of the life support systems, I believe I was talking to a reporter.

At that time, the technician, Lance LaBrache, who had done the high pressure piping for me and was involved in the testing, came in and said, "We have a problem." I said, "What do you mean?" He showed me some black material that had blown out of one of the lines, and as it turned out, it was the ball valves that had graphite in them. We had to pull that entire system down, clean it again and start all over.

A major stumbling block occurred one Friday morning. I came into work and one of the leading men in the shop, Bill Hodges, called me and said, "Bill, you need to come down here. We've got a problem." I said, "What is wrong now?" He said, "Well, we've got a cracked weld." I went down to check it out. The legs were attached to the SeaLab hull with doubler plates to better distribute the load on the hull. These plates were cut from scrap hull material and were two feet square and three-quarters of an inch thick. The plates were attached to the hull by continuous three-quarters of an inch fillet welds on all four sides and had been in place for several weeks. One of those welds had opened up with a ten inch crack. The drawings for the floats had called out high tensile hull plate for the material. Therefore, we had selected the 125 low hydrogen rods that were specified for that material. We took a sample of the metal and sent

it over to the Pensacola Naval Air Station to be analyzed. They reported that it was similar to HY80, with which we had no experience.

I called over to the Biloxi Shipyard, and we were able to get a Navy commander, whose name I don't recall, to come over and look at our problem. He was knowledgeable of HY80 welding. He came over, and after looking at our problem, he said, "Well, the only thing you can do is go up to Charleston and get a couple of HY80-qualified welders and bring them down here to finish this job." At the time, I had already called in a x-ray crew and they were x-raying all the welds. We got the x-rays while the commander was there, and we looked at them. Only about ten percent of the welds were defective, and that was out of over 600 feet of welds. He said, "Well, you've got some good welders. I'm amazed that the welds are this good."

INTERVIEWER: It was all done at the lab?

MR. CULPEPPER: Yes. I told him, "Well, we had a problem to start with. They were tacking the plates onto the hull, a tack each corner. By the time they'd get to the last corner, the first corner was cracked. I told the welders to put on temporary clamps and run a bead all the way down the first side, immediately chipping the bead and running the next pass. I told them to keep it going and keep it hot. That was what seemed to work.

As it turned out, the commander gave us procedures for HY80 welding. We only had three welders in the welding shop at the time. One of the requirements was that if welding was interrupted, that weld and the heat-affected area must be thoroughly ground back to base metal, plus all sorts of re-prepping before you could start over again.

The last weld we had was the nose section to the hull, which was nine feet in diameter, requiring a 27-foot long, 21 pass weld, and we needed to preheat to 150 degrees Fahrenheit. Time was running out, so we decided to weld continuously, day and night, until we finished. I

had our three welders make the required sample welds using the HY80 procedures. All three passed with no problems. All defective welds were repaired and passed inspection.

Out on the pier was the only place we had to build this thing. We didn't have a house big enough to put it in, so they rigged up a makeshift heater, which consisted of a welding machine hooked to a steel band wrapped around the hull. Then, we paired two welders together and one welder with a helper. While one guy welded, the other one used a gas torch to preheat ahead. He used a temple stick to determine the temperature. They welded for 72 hours, 12 hours on, 12 hours off, to complete it. The weld was x-rayed and passed inspection.

INTERVIEWER: With all these unknowns and difficulties, still, in three months of time, you had a habitat ready to go in the water? Now, can you talk a little bit about the first operation, putting it in the water? It was actually tested out here, wasn't it?

MR. CULPEPPER: Yes. That's the sad part. They took it out on Friday, May 22. We anticipated that they were going to have some problems in handling because they really were not set up for it. They had the YFNB12, which was a barge. They had winches on the fantail with wire rope. They had a big fair lead, a roller fair lead, over the fantail, and they were planning to shackle the wire rope to the SeaLab.

Another story is the ballasting. Back then, lead cost 12 cents a pound, out of standard stock, and I could not buy 120,000 pounds of lead. I ended up at the Bayline Train Depot. I bought used railroad axles for five cents a pound. We had 167 of them, and those had to be put in the ballast bins with a small overhead winch that was supported by an overhead steel beam that extended out over the stern.

Another complication was the fact that there were three sizes of railroad axles, and there were six ballast bins on the SeaLab. The axles weighed about 550, 700, and 900 pounds each. I calculated the number of axles of each size to place in each bin.

INTERVIEWER: You wanted to go down?

MR. CULPEPPER: We wanted to go to level. I thought that was the best way.

INTERVIEWER: Yeah.

MR. CULPEPPER: Anyway, they were ballasting the thing down, and we had about a state two sea, maybe, with around three foot swells or so. It was enough that when the barge came up, it snapped that wire rope pretty tightly, and it got to the point at which it almost took off a sailor's leg. That was when they decided to change things.

They had a large air winch forward of amidships that they had been using for some previous project work. The winch was big, but it didn't have a lot of load capacity. There was also a set of two biaxial traction winches aft of the forward winch, and they had some nine inch nylon line. They reeved that line on the forward winch, then around those biaxial winch drums in figure eights about four or six times, then back to the fantail, which was about 120 feet or so. We talked them into using that nylon line because it had stretch, and it would tend to absorb the shock of relative motion between the barge and the SeaLab.

The next problem went like this. Since we could not afford a water tight hatch, both the main entrance hatch and the air space hatch covers were bolted on with flat rubber gaskets. Unfortunately, they required some 18 to 24 bolts each. Because of the anticipated difficulty in removing the hatch on the bottom, someone made the decision to lower the habitat with the main hatch cover removed. The plan was to keep the internal pressure above ambient during the lowering process by using air through the air supply hose. Well, the air hose had been specified

to be a half inch dive hose and 1000 feet long. The pressure loss through thousand feet of hose to the regulator below was great enough that the air supply could not provide sufficient flow. As it began to go negative while they were adding axles, which were not all in yet, a swell came along, and seawater apparently went up into the entrance hatch, flooding the inside. After one or two more waves, the SeaLab went quickly to the bottom, in 54 feet of water. It was half full of seawater, so they had to try to recover the habitat.

INTERVIEWER: The air hose just couldn't keep up?

MR. CULPEPPER: No. But after the SeaLab was on the bottom, continued pumping dewatered the SeaLab enough, and by removing axles three and four, it become buoyant. It was then a matter of surface handling, to control ascent as air bubbled out of the hatch. Once on the surface, more seawater was blown out, the hatch was reinstalled, and we returned to the Navy base. That was Sunday afternoon, May 24.

INTERVIEWER: This was at stage two?

MR. CULPEPPER: Yes. They brought it back in and put it on the pier Sunday afternoon. Bob Porter and I went in and started cleaning it up. It was fully provisioned. Toilet paper was everywhere and in everything. We had to pull out and wash all the electrical receptacles. Regulators were disassembled and cleaned. Everything had to be washed down and cleaned up. All the labels were coming off of the cans. Anyway, it was ready to go back out on Tuesday, May 26.

INTERVIEWER: That's great. Did you have to replace all the electrical systems?

MR. CULPEPPER: No. We just washed them down. They took it back out to the Stage II platform off Panama City. During the sea tests, we were out of the loop. They had shot the

engineers, so all we could do is stand by and cringe. Somebody else was in charge. Anyway, they took it back out and put it on the bottom without incident.

INTERVIEWER: What did you change to get it on the bottom the second time?

MR. CULPEPPER: We left that hatch on until it was on the bottom. Then, we took it off. I'm not sure. We may have improved the air flow, too.

INTERVIEWER: Now, you couldn't get air in there until you had the hatch opened, could you?

MR. CULPEPPER: No. The hatch could not be removed until the internal pressure was equalized. Ambient pressure would be higher, preventing hatch removal.

INTERVIEWER: The air hose would go in?

MR. CULPEPPER: No. The air hose went through the umbilical tube. The air regulator was in the air space.

INTERVIEWER: I see.

MR. CULPEPPER: We got it on the bottom. We got it open. Captain Bond went down and spent the night in it. He wrote a wonderful story about it. The SeaLab was successfully surfaced, returned to the Navy base and loaded onto the YFNB 12. A tug took it in tow on Saturday, June 6, and arrived in Bermuda on June 12.

When they got to Bermuda about two weeks later, and this was back when the fiscal year ended on June 30, Bob and I were permitted to go down the first week to get it on the bottom and witness the startup of the operation.

INTERVIEWER: Was that Bob Barnes?

MR. CULPEPPER: No. It was Bob Porter, the electrical engineer. Jim Bladh was there, too. We went down during the last week in June. All of our divers were out hunting for bodies from an Air Force plane that had augured near Bermuda, so nothing was happening. We were supposed

to come back in a week. Well, nothing had been done. We called home. They said, "Okay. We'll send you some more money. Go ahead and get in your funds request." We got some more money. We stayed another week. We ended up staying for a month, and they finally got it down, but not before they flooded it again.

This time was different. The commode, the head, had a three-inch drain line, a through-hull drain line. For double protection, we had a stop valve inside and a pipe cap on the pipe outside. We had provided two ten-foot sections of fire suction hose, which would attach to that pipe on the outside and take the effluent away from the habitat. However, the pipe cap was not to be removed, nor the hose attached, until the SeaLab was on the bottom and pressure equalized. During the pre-dive check, someone forgot to close the hull valve. That was the first mistake.

Again, someone decided it would be easier done on the surface, so it was the same scenario. The habitat was half full of seawater, but this time, it was in 187 feet of water. The nine-inch nylon hawser was stretching big time. You could see a little fish hook on the hawser, moving fore and aft a distance of up to eight feet. The deck had footmarks on it. We were in rolling swells of about six to seven feet. Captain Bond and I were on the aft bridge walkway, looking down on this operation. I could see that fish hook going eight feet back and forth. Then, the line started smoking. They broke out a fire hose and sprayed it down to keep it from burning. Again, we got to take the railroad axles out, blow it down, get it back to the surface, take it back in, and put it on the pier. Bob Porter and I got to clean it up again. I'm not lying. We got in and started cleaning it up. At quitting time, everybody went ashore except Andy Anderson. He was the only one that stayed there and helped us. I really don't remember how many days lapsed between that incident and getting back out the next time, but it was more than one.

The next day was a long, green table, and there was some very serious consideration of canceling the project at that point. There were questions like, "Now, what makes you think it's going to work the next time?" But we finally got an okay to try it one more time. That time, we took it back out. Everything went great. Then, we got it on the bottom and got it manned.

INTERVIEWER: You had all the valves closed and the hatch was closed?

MR. CULPEPPER: Yes. I personally checked.

INTERVIEWER: You made it slightly negative? Was that the idea, to be slightly negative to allow you to lower it down?

MR. CULPEPPER: It was about 3,000 pounds negative for lowering. I had planned to have it 15,000 negative for good bottom stability. I wanted it very negative so that it was not going to move or float away in any current. That was one of the questions that Captain Melson had for me while we had it on the pier that last time in Bermuda. He said, "Now, how about your righting moment?" I said, "Well, you know, we have that big hull up top, and we have the ballast on the bottom. This thing is 14 feet wide." He said, "Well, what current did you design for it?" I think I told him three knots. He replied, "What coefficient of drag did you use?" I told him it was 1.25, or whatever it was. He was satisfied with that. "Besides, Captain Melson," I said, "It's not going to turn over. It might walk a little due to turbulence, but it's never going to turn over. There's just too much buoyancy there for it to do that."

INTERVIEWER: Did you add extra ballast after it was on the bottom?

MR. CULPEPPER: Yes, for a total of 15,000 negative.

INTERVIEWER: Once you got the habitat on the bottom, the divers simply dove down?

MR. CULPEPPER: No. We had a personnel transfer capsule (PTC).

INTERVIEWER: You had a capsule.

MR. CULPEPPER: We had a single lock steel chamber, and we rigged it up vertically with a framework and a platform underneath the lock and ballast in the platform. Jim Bladh operated it. He bragged about getting in on the bottom, 187 feet down, in five minutes. The aquanauts were transported to the bottom in the PTC, from which they swam over to the SeaLab.

INTERVIEWER: Now, the intention was that they were going to actually decompress inside the habitat as it was raised?

MR. CULPEPPER: Yes. The habitat was slowly raised toward the surface without problem until it reached 81 feet. At that point, surface wave action caused shock loading in excess of twenty tons on the Argus Island crane. The aquanauts were then transferred to the submersible decompression chamber via the PTC and brought to the surface to finish decompression. .

INTERVIEWER: You said you weren't actually down there during that.

MR. CULPEPPER: No. We left after the first few days of operation, three or four days, maybe. I was there long enough. One of the chores that Jim Bladh and I had was patching holes in the Zodiacs, keeping them afloat.

INTERVIEWER: With all the problems, it still ended up to be an incredible success?

MR. CULPEPPER: Oh, yeah. It was great. We lost one light bulb in the operation. It was rather fantastic, I thought.

INTERVIEWER: Now, you were saying that it came very close to being canceled after that second flooding?

MR. CULPEPPER: Yes.

INTERVIEWER: Shortly after SeaLab I, SeaLab II had to start very quickly.

MR. CULPEPPER: Yes. We finished up all the paper work and reports probably in October or November in 1964. During the same time frame, Tom Odum and I attended a SeaLab II planning meeting at Scripps Institute, which was to be the SeaLab II test site and base of operations.

After that, I accompanied Captain Melson and Al O'Neal, of the Office of Naval Research, to Hunter's Point Naval Shipyard. Before we arrived I asked Captain Melson why I was going to Hunter's Point. He replied that he wanted me to show them how to design SeaLab II. I answered, "Yes sir, but I had never worked with a shipyard before," and I had no idea what was ahead. The meeting went well, and the shipyard was agreeable to accepting the challenge.

In January, we had the first organizational meeting for SeaLab II. It was held in Panama City, and folks from Hunter's Point come down. Larry Ju headed the Design Division there. He came down. We had previously put together a PERT chart for the operation. It started in January and was to be completed in October. The PERT chart was reviewed and met with general agreement. We missed the schedule by two weeks.

INTERVIEWER: That's just unheard of today.

MR. CULPEPPER: The habitat was designed and built, starting in February, and it was delivered in July. We were present at the shipyard, Hunter's Point. I had people out there almost continuously for that six months. I was there for at least half the time. One of the interesting things that developed was that Larry Ju wanted to design the habitat similar to a submarine. He wanted to put the variable ballast down low, with tanks on either side. My position was that we wanted that area clear so the guys inside could look outs and observe the bottom. It came to a standoff late one afternoon. There were six or eight of us in the conference room. Ed Carpenter, a mechanical engineer from the Naval Ordnance Test Station in Pasadena, was there to provide final outfitting support at Long Beach Naval Shipyard, the surface support vessel, and some

onsite support. Larry just wouldn't move. He said, "You know, it's got to be designed like a submarine." I said, "No. It does not. Put the weight low and ballast up high." I had gotten up to go the bathroom. When I came out, I stopped to get a drink of water. Ed Carpenter was out there, and he said, "Bill, you've got to call back to Panama City to change this." I said, "I don't have to call anybody. I made the decision." We went back in. He said, "Larry, Bill has made the decision. You don't have to call anybody in Panama City." He threw up his hands and left the room. Later on, we became very good friends.

INTERVIEWER: What were some of the fundamental changes, or differences, between SeaLab I and SeaLab II?

MR. CULPEPPER: Well, SeaLab I was the initial operation. "Let's see if we can do it," we thought, "Let's do it in nice, warm, clear water, the best environment, with no extraneous studies or experiments. SeaLab II was in a dark, cold environment and a much larger operation. There were ten guys instead of four, with two week periods for three teams. There was a lot more of experiments, studies, equipment evaluations, underwater tasks, etcetera. SeaLab II was designed to test a lot of equipment, diver heating, communications, dolphin work, salvage, tools, studies, and all sorts of things. It was a little deeper, but only by 200 feet, which was not that much.

Of course, we had a little more time to design and build. We had twice the time frame. Instead of three months, we had six months. That was great, but the job was much larger and more complicated. One of the key things in SeaLab II was the role for which Panama City was responsible. Our group provided design concept drawings, sketches, written specifications and general guidance to the shipyard for all the designing and building they were assigned. We provided the specifications and technical support for the development and procurement of the personnel transfer system. We tested, evaluated and modified, as necessary, many of the

components that were to be installed in or on the habitat. We coordinated the efforts and interfaces between eight major activities involved directly in the operation.

SeaLab II differed in many respects from SeaLab I. The hull was designed for a 15 psi differential, since we felt we could control internal pressure during descent within those limits. It had bigger view ports. Our first ones were six inches, maybe. These were 18 inches, to better observe the surrounding sea floor. The hull was 12 feet in diameter, 57 seven feet long and three quarters of an inch thick.

We had learned a lot from SeaLab I. For instance, with the refrigerator, we put in an indoor switch that cut off the inside fan, to prevent the cold from being blown out when opened. We also made sure the temperature controller would work in the higher pressure environment. For the DH machine, we increased the power of the motor to handle the denser atmosphere, and we overdid that and had to back off some on that later. We didn't have an air space in this habitat, so we put sensitive things in pressure-tight containers, or we modified them to become non-pressure sensitive. We used rough service light bulbs and pressure tested them to twice the operating pressure. They were more rugged than a regular incandescent bulb. We did not use thermal circuit breakers but substituted magnetic/hydraulic circuit breakers because of the greater heat transfer rate in the hyperbaric helium-oxygen atmosphere. One major problem arose in the procurement of the dished heads for the hull. The steel workers were on a strike, and the only response we got was from Lukens Steel. They required six months of lead time. That was our entire schedule.

The design people tried to come up with other solutions, from flat plates to cones and others, but all were rejected because of stress analysis difficulties. As it turned out, the semi-elliptic dished head was the simplest thing we could use. Mal McKinnon, who was a lieutenant

commander at the time, asked, "Why don't we form them explosively?" The design people replied that they had never done that before. Mal reminded them that they had formed some heads for a previous project. The reply was, "Those were only three feet in diameter." He said, "Well, these are only twelve." He was a real optimist. Anyway, they decided to go along with it, and sure enough, they made up a big concrete mold and clamped a plate on it, set some shaped charges out in front of it, lowered it down to water, and blew it up. A wrinkled mass and partially formed head came up. Then, someone said, "Maybe we ought to evacuate the cavity before we try this again." They put a tap in the back of the form, pulled a vacuum on it and went, bang, bang, and they had two perfect heads. It worked very well.

INTERVIEWER: That was an innovation, something never been tried before?

MR. CULPEPPER: That was probably one of the reasons that Mal made admiral, and it was key to maintaining the schedule.

INTERVIEWER: What about the hull penetrations? You said that in SeaLab I, you decided to come in through the bottom.

MR. CULPEPPER: Yes. This time, we used packing glands, but we put all of them down low, so they were actually at or near the water line in the habitat. We used good packing glands. Those were rigidly inspected. That was not a problem.

One of the interesting things that happened was at the end of the 24 hour air pressure test, the habitat was vented too quickly and a large portion of the cork insulation, which had been plastered over for appearance, was blown off the hull. It didn't take too long to replace it, though. The pressure test was otherwise successful.

In July, the habitat was barged down to Long Beach Naval Shipyard for a final outfitting. We had it on the pier there and did all those kind of things. We had an interesting experience in

the shipyard. We had designed a diver way station so that divers out in the water, if they got in trouble, could pop up into a dry atmosphere, or gas bubble. It was sort of a do-it-yourself project, something that the divers could do after they were on the bottom.

INTERVIEWER: Did they assemble it?

MR. CULPEPPER: Well, they did not assemble it, but placed it, set it up, ballasted down, dewatered it, and all that. I was fortunate to have Bill Frost, who was a naval architect, and also the grandson of Robert Frost, the poet, working with me at that time. He was also into value engineering (VE). He used some of his VE and came up with a neat little design. He used three residential fuel oil tanks. I think they were 175 gallon fuel tanks, and they were about 24 by 36 inches in a cross section and about 48 inches long. The narrow sides were rounded, and the top and bottom were flat. Bill took two of those, set them up lengthwise and cut the tops out of them. He took the other one, cut the top end out of it, turned it upside down, placed it on top of and between the other two, and then welded the three together. He cut square holes in the sides of the upper one and put two Plexiglas windows in it for view ports. That was neat. They could move that thing to the bottom, and the divers could shovel in mud or dirt, or whatever was on the bottom, into the side tanks and then dewater the center tank. We had a set of drawings that we sent to the Long Beach metal shop, apparently by way of a scheduler. The leading man in the shop called me up. He wanted me to come over. He had some questions about the drawings; he couldn't understand them. I went over. He had some questions, which I thought were kind of dumb, but I tried to explain them to him. He said, "Well, you don't specify the thickness of the material. Would an eighth of an inch be all right?" I said, "Wait a minute. On the list of materials, it calls for an oil tank. You go buy three oil tanks and weld them together." He answered, "Oh, we don't do that around here. We build the darned thing." That took more time.

They did. We got some real experience in how some shipyards worked. You'd have a little welding job, maybe a thirty minute job or so. The welder's helper showed up, and he sat around for a couple of hours. We said, "Where is the welder?" He said, "I don't know, but I can't do anything until he gets here." I think he spent a half a day doing nothing. The welder finally got there. They did the job and were gone. We had a HOOKAH, or push-pull breathing rig, furnished by Westinghouse. We had a few problems with it. We had to reconfigure and rework it to get it installed in the habitat.

We got everything together and put the habitat in the water. That was the only time I went down with it, in 12 feet of water. I noticed one of the view ports was leaking. There was just a trickle of water inside. I think we pulled it up and reworked it some. But that wasn't a great concern because we would normally have an positive internal pressure differential and did not feel that it would be a problem.

INTERVIEWER: It was a whole different operation from the construction of SeaLab I?

MR. CULPEPPER: Yes.

INTERVIEWER: How much did it cost to build SeaLab II? Do you know?

MR. CULPEPPER: It cost about three million dollars for the entire operation, if I remember correctly. The habitat was subsequently moved down to La Jolla, to the Scripps Institute. Scripps had already run the water line, power and communications/electronics lines and other support systems. They had put in one three-quarter inch water line, which would not flow the required 10 gpm to operate the showers.

INTERVIEWER: That was like a mile long or so, wasn't it? How long was that hose?

MR. CULPEPPER: It was 3500 feet long, and it was plastic pipe.

INTERVIEWER: It was 3500 feet?

MR. CULPEPPER: Yes. It wasn't too far, to 200 feet of water out there. Anyway, I asked, "How did you decide to do that?" They answered, "Well, that's what we had," or whatever. I said, "We need more capacity than that," so they went out and laid another line. Some problems developed here and there, as would be expected in such an operation, with a number of activities and a tight schedule. What I was trying to do was coordinate those efforts to minimize the holdups.

There were eight activities involved that we, the Panama City group, coordinated with the others, as required. We didn't use interface drawings like they did on SeaLab III, but ours worked and theirs did not. Generally, where we had an interface between two activities, I would task one activity with both sides of that interface. In that way, when it all came together, everything fit. It went pretty smoothly.

We had a helium tube truck on site in the water on a Mike Boat, and Mal McKinnon was there. He said, "Bill, we're going to have to send this tube truck back whether we use the helium or not. We've had it too long. What do you think? We could just go ahead and put it in the habitat, and when we get ready to go down, we'll just be that much further ahead." I said, "Well, you can put it in there, but it will be gone before you get down with it." He asked, "What do you mean?" I said, "Well, we had a small water leak in one view port at 12 feet in Long Beach. It isn't going to hold helium on the surface." He said, "We've got nothing to lose. Let's try it anyway." I said sure. I went back out the next morning. I asked Mal, "Now, what's the pressure in the habitat?" He answered, "One atmosphere." But SeaLab II went down without incident.

One thing that happened in Long Beach that I thought would be of interest had to do with the PTC. Walt Mazzone worked on clocks. He made clocks as a hobby and had designed a Geneva mechanism for the escape winch on the PTC, something that would let it come up at a controlled rate from a weighted platform on the bottom of the PTC support. It could be operated

from inside the PTC in case they needed go to the surface without surface support, such as a crane to lift them. This thing was monstrous. It had about a three, three and a half, maybe four-foot long, two-inch diameter steel lever arm with a large steel counterweight at the upper end. The ratchet wheel was attached to the winch spool and was positioned at the lower end of the pivoted lever arm. It looked quiet impressive. The PTC was lowered to the bottom pier side for the initial test of the raising mechanism. To everyone's surprise, when the system was activated, the PTC rose rapidly, apparently out of control, splashing to the surface.

Well, Bill Frost and I got the drawings out, and we were in the ward room on the USS *Berkone*, the support ship. We had a half a dozen people looking over our shoulders, including the division heads, branch heads and people like that, trying to solve the problem for us. We finally said, "If you guys would go away, maybe we could solve the problem."

Well, they had used FORMICA, a laminated melamine plastic material, for the water-lubricated bearings in the mechanism. At this time, this material was used extensively in underwater applications, such as ship propeller bearings. I had had some experience with those in my mine countermeasures days.

Normally, the rough bearings were soaked in water for thirty days before the final machining. They had to be used immediately, or kept wet until used, or they would dry out and shrink. The inside and outside diameters would increase or decrease, causing excess radial clearance between the shaft journal, bearing and bearing housing. That was what had happened. They had originally machined up at the true dimension, but they had been sitting in the dry for weeks and had shrunk so much that everything had too much clearance. The ratchet wheel and lever arm didn't make contact. It just freewheeled. I had used Teflon bearings in some of my

underwater mine countermeasures equipment, so we managed to find some Teflon and had new bearings machined and installed. It worked fine.

INTERVIEWER: They weren't actually decompressing?

MR. CULPEPPER: No. They were under pressure.

INTERVIEWER: They sealed the hatch and it was then brought to the surface at a controlled rate?

MR. CULPEPPER: Yes. They heard, "This is an emergency. You don't have a surface support, but you want to get to the surface." This was a precaution. If the habitat became contaminated and nobody was manning the crane. It was a backup.

One of the other problems involved the deck chamber and the PTC. It was the first PTC/deck chamber complex built for the Navy. We had the chamber on the second deck of the ship. The PTC, of course, sat on top of it. The PTC was vertically oriented and had seats around the inside, circumferential seats, at two levels. Five guys could sit on each level. During the first test of the decompression complex, we found that there was no way to vent the pressure in the trunk between the PTC and the deck chamber. The two could not be separated. Walt Mazzone came up with the idea of using a syringe needle. There was a face seal O-ring in between the two chambers. They inserted the syringe through the O-ring and let it bleed down that way.

INTERVIEWER: This was actually at the site?

MR. CULPEPPER: No. This was on the surface support vessel at Long Beach.

INTERVIEWER: It had never been tested at Long Beach before?

MR. CULPEPPER: No. We had a lot of things like that happen, but we worked together and with all hands cooperating, most problems were solved without serious results.

After the habitat was on the bottom and manned, we had a problem with the television cameras. They were inside the habitat, and they worked fine for a day or two or three. I don't remember the exact time, but they would screw up. We'd take them out, bring them topside and check them out. There would be nothing wrong with them. We would put them back together, take them back down in the pressure cooker and put them back in. They'd work for two or three days, or whatever it was, and they'd screw up again. Finally, the third time this happened, the technician who was working on them happened to notice that when he opened the housing, there was a slight hissing sound. Then, we figured out what was happening. The helium was getting inside this watertight camera housing, which was good for 10,000 FSW, and it was detuning the camera. We rigged up some mounts on the outside, in the water, looking through the portholes, and they worked fine.

INTERVIEWER: It was a lessons learned through experience.

MR. CULPEPPER: We used electrowriters so that the aquanauts could write messages on the bottom unit and it would be transcribed on a topside unit. The helium speech unscramblers were not very good at that point in time, especially with Scott Carpenter. I just could not understand him at all. We pressure tested the electrowriters, and when we decompressed them, the capacitors, the oil filled capacitors blew up. They had absorbed helium. We found that we had to decompress them or replace the oil filled capacitors with dry capacitors. Then, we had no more problems with that.

But we found a lot of unique problems, particularly in the helium hyperbaric atmosphere. We did a lot of research in developing film coefficients for use in calculating heat loss for the habitat and subsequently, how much heat capacity would be needed to maintain a comfortable environment. We relied heavily on the services of a consultant at the University of Florida in this

effort, with Jim Fyfe successfully supporting the effort for us. Jim's theoretical calculated heat loss was 54,300 btu per hour. The average measured during the operation was 60,000 btu per hour.

INTERVIEWER: You were blazing new trails then.

MR. CULPEPPER: Yes. We also developed a relative humidity chart to use in that environment. Jim Fyfe did those. We found that the guys liked to keep the temperature around 85 or 87 degrees, to be comfortable because of the high heat transfer of the atmosphere.

INTERVIEWER: How long were you actually in California? Was it for the entire operation or you were coming back and forth?

MR. CULPEPPER: Well, I was there about half the time, back and forth during the design and fabrication at Hunter's Point. But some of our team members were there almost continuously. I was in Long Beach continuously during the final outfitting, and at San Diego during the operation. We were there for some three months. I did leave a little before the operation was completed. We went out in July, the first week in July, I believe, and stayed through August and September. We left around the first of October, and it didn't finish up for a week or two after that.

Bob Porter and I then went back out for the surfacing of the habitat because our team was responsible for the engineering evaluation. We planned a complete inspection of the habitat and all systems and equipment. During the raising, operation problems were encountered with maintaining an over pressure in the habitat, and partial flooding occurred. There were about six inches of seawater on the deck. Again, Bob Porter and I enjoyed cleaning up and conducting our inspection. I remember the skin on our feet peeling off from the lithium hydroxide in the water. The scrubber cans were down low near the deck.

INTERVIEWER: Now, what caused the flooding?

MR. CULPEPPER: It was caused by the inability to maintain an over pressure inside the habitat. It was not a big issue.

INTERVIEWER: Yes. That was 1965. Was it an immediate decision to go with SeaLab III or was there some delay?

MR. CULPEPPER: It was not immediate. During this time, the Office of Naval Research had sponsored SeaLab I and SeaLab II, but the Deep Submergence Systems Project Office took it over at SeaLab III. We finished that in 1965. I want to say that it was the next year that SeaLab III began.

The most astonishing thing happened when we had the first organizational meeting at Hunter's Point. We had a big meeting, and Commander Jack Tomskey, the project officer, made the statement that the people who were involved in SeaLab I and II would not be technically involved in SeaLab III. We ended up being tasked with the engineering evaluation after the fact. We were also to provide some equipment, such as a combination washer/dryer unit, an infrared oven, and a carbon monoxide burner.

INTERVIEWER: Was there a reason? Did they give a reason?

MR. CULPEPPER: No..

INTERVIEWER: Essentially, it was the same habitat, but it was modified into SeaLab III? It was the same as the habitat for SeaLab II?

MR. CULPEPPER: Yeah. They used the same hull, but they added a big room on each end underneath the hull. I think the one on the entry end was primarily like a dive locker. There were spaces and hangers for dive gear and the showers, and all that stuff, to make more room inside

the main hull. The other end contained a freezer and other storage space, plus the emergency exit.

One of the things that happened to SeaLab II was, with all the survey work they had done at the habitat bottom site, they had determined that the grade was three percent. We decided that leveling jacks would not be needed. But when the habitat was manned, they found that the bottom grade was near ten degrees. That was where they got the name, the 'Tiltin' Hilton.'

On SeaLab III, they wiped the bottom structure off and made an anchor, in effect, with the habitat articulated above, so no matter what attitude, the bottom was the habitat would hopefully float at level.

In Panama City, we sent out requests for quotes for a washer/dryer unit. Although we had not RFQ'd Sears, that was the only quote we received. We bought the Sears unit but found that it was too large to fit through the EOD chamber lock for pressure testing. We called Sears and ordered a technician to come out to disassemble the unit and then reassemble it inside the chamber. After a successful pressure test, the Sears procedure was reversed.

We also procured, modified, and tested an infrared oven, as well as designed and tested a carbon monoxide burner. This unit utilized a heated catalytic bed to convert carbon monoxide to carbon dioxide and was designed by Ray Bentz. The operation started out badly. In doing our engineering evaluation, we had everything instrumented. We had flow meters on all the gas lines and sensors on all the electrical systems, the motors and things of that nature.

While the habitat was pier side, in Long Beach, we were doing our final checkout, and in checking the motors, like the scrubber motor and DH pump, a total of six three phase motors,

we found that all but one was running backwards. The electrical system was monitored by a frequency meter to indicate the proper power phase connection. The meter indicated that the phasing was correct. But Bob, wanting to be sure, went up to the electrical shop and got another frequency meter, which was good, and brought it down to check it out. He determined that the installed meter was defective. We reversed two of the shore power leads and then, five motors were running right, and the DH pump motor was running backwards. We rewired the DH motor to make it run forward.

When we were at the site and they were doing the surface checkout after hooking up the power, they found that all motors were running backwards. Someone in the group noted that my team had made some changes to the electrical system in Long Beach, and I was in trouble for not reporting the fact. I informed them of what we had done at Long Beach and that the frequency meter was defective. The shipyard folks said that was not possible because they had built it in strict accordance with the drawings.

In answer to the question ‘what do we do now?’ I suggested to Ed Carpenter that if he went down to the shipboard power panel and reversed any two leads, everything would be fine. It was. The next morning at breakfast, I was told that I was right and a new meter had been obtained and installed in the habitat. But for what? It didn't make any difference at that point in time. Everything was hooked up and running correctly.

The next problem surfaced when we found that the heaters inside the habitat had not been turned on before the habitat was lowered. It was at 600 feet, in 45 degree water, with no heat. The next question was how long it would take to heat it up after we got inside and turned everything on. We went back to the beach and worked for several hours that night, calculating

how long it would take to heat it up. I don't remember the number now, but I remember it was quite a number of hours.

The next problem was that the habitat was leaking gas at a significant rate. There was an urgency to get someone into the habitat to try to stop the leaks. The night before they pressed the divers down, Berry Cannon and I had a room together. I didn't have a room at that time. He did. He had a double bunk. We had breakfast together and went out to the support vessel. I was the last guy to talk to him before he went into the chamber. I asked him if this would be his last dive and he answered no, he wanted to go to 1000 feet. I wished him good luck and we shook hands.

Berry and Bob Barth were on the first team. They were selected to go down first, open the habitat and check out all systems. That night, Wally Jenkins and I were ashore and had our engineering van manned and monitoring all the systems in the habitat. In order to try to stop the leakage of gas, Berry and Bob were lowered to the habitat but could not open the hatch and were returned to the surface chamber. There was no heat in the PTC, nor was there any surface supplied heat to the divers. At 600 feet in 45-degree water breathing helium, hypothermia was a real problem. The divers were very cold.

INTERVIEWER: Now, was that an oversight or did it just not have heat?

MR. CULPEPPER: It just wasn't there. We designed and fabricated PTC and diver heating systems for the MK II Dive System later on. Due to the concern over the loss of helium with only a limited supply, another attempt to occupy the habitat was made about one in the morning. On that dive, Bob said that he had gone off to look for a crowbar, or something to pry the hatch open. That was when Barry passed out. Bob went back to him, but was too weak to pull him

back to the PTC. Blackie Blackburn was the PTC operator. I talked to Blackie personally. He said that he went in the water and pulled Berry back into the PTC. I said, "Well, how was it?" He said, "It was cold. Going in that water was just like jumping into ice water." Berry was pronounced dead after returning to the surface.

INTERVIEWER: They had no hot water suits or anything? They had just wet suits? MR.

CULPEPPER: No. There was no heat from the surface. All of the heating systems were on the habitat.

INTERVIEWER: Now, what was the reason that they couldn't open the hatch? Was there a differential pressure on the inside?

MR. CULPEPPER: They had a four square foot entry hatch on the habitat. The hatch was counter weighted. It had a cable/pulley/counterweight system to offset the hatch weight, but a half a psi differential is 1200 pounds or so. Since they were supplying gas to prevent flooding, it was certainly possible that there could be internal over pressure. Things got worse after that. They were running out of helium and pumped air down to prevent flooding. The surface support also wasn't rigged to bring that thing back up. They spent the night re-rigging from the lowering mode to rigging up so that they could bring it to the surface. They brought it up the next day.

INTERVIEWER: It was negatively buoyed? They had to winch it to the surface?

MR. CULPEPPER: Yes. They could blow the variable ballast and maintain a small negative buoyancy. I was in a cloud during that time. Nobody would talk to me. Tomsy and Nicholson were both there, and I wanted to know why this thing happened. Wally Jenkins and I had gone out that morning. It was before daylight. We went down to the pier and got on the boat to go out. Mike Greenwood was on the boat, and he said, "Hey, guys. I'm sure you probably don't know,

but Berry is dead." That was the first we knew. They had probably called Mike during the night or something.

INTERVIEWER: Now, what was the atmosphere on the surface there? Was it chaotic?

MR. CULPEPPER: It was quiet.

INTERVIEWER: This was after or before when they were trying to get into the habitat?

MR. CULPEPPER: It was after. I wasn't there. I was ashore, asleep. I knew nothing about it.

We thought they were going to go down the next morning and open it up. Apparently, with the leaking they had, they decided to go sooner. It was either try it or scratch the project at that point.

INTERVIEWER: My understanding is that there was an empty canister in Berry Cannon's rig.

MR. CULPEPPER: Yeah.

INTERVIEWER: How could that have possibly happened? Have you thought about that?

MR. CULPEPPER: I never really believed it until fairly recently. Bob Barth and I were talking about the last SeaLab reunion. Somehow, we brought up P.A., or Paul, Wells' name. He said that he tried to get Paul to come to the reunion, but Paul wouldn't come. I said, "Well, does he believe he's responsible for Berry?" He said, "Well, sure he does." Up until that time, I had assumed that he had just died of hypothermia. I just didn't believe that could happen. I knew P.A. too well to feel like that he would let something like that happen. Apparently, it did happen.

INTERVIEWER: Now, I've heard some people even say that they thought that there could be a chance of sabotage.

MR. CULPEPPER: Yeah. I've heard that, but I figured that it was somebody trying to lay the blame somewhere else. I don't know. I just don't have any background or any information to

express an opinion about how it might have happened. I felt that with P.A. in charge, something like that would not have happened. I won't say that it was P.A.'s fault, other than the fact that he was in charge. I don't know that he was supposed to personally check the rigs or whether somebody else was assigned that responsibility and didn't do it or what.

INTERVIEWER: Now, at the point after Barry Cannon's death, was a decision made to cancel SeaLab III?

MR. CULPEPPER: I don't recall any decision being made. First of all, we had to go through Berry's personal belongings and itemize all that stuff. We then went to a memorial service in San Diego. Then, I went to the airport to get a flight back to Panama City. I called my good friend, Danny Roberts, because I couldn't get a plane. He called the manager out there and got me on a plane somehow. That got me back to Panama City. Shortly thereafter, we went to Berry's funeral. As soon as the funeral was over, my family and I took a week off and went down to a park near Ocala and spent a week and relaxed.

INTERVIEWER: Now, obviously, SeaLab III was a much more ambitious project than the other two?

MR. CULPEPPER: It cost thirty million dollars.

INTERVIEWER: I guess there were more people involved in the whole process, also?

MR. CULPEPPER: There were many, many more. I really don't know and am not able to say how many, but there were many folks. Just the Steering Task Group meeting was attended by large roomful of people. All the minutes were taken verbatim by a transcriber, and the minutes of the meeting were like a Sears catalog, with every statement that anybody made. The modus operandi was that all the activities involved were going to be inter-coordinated by a contractor

who sent people to Panama City, and they'd go through every task that we had. "Where are you? What's this? What's that?" They had the latest drawings, and they were supposed to be tying all this stuff together, particularly the interfaces, making sure the interfaces were going to work and all that. They had some good people involved. Dr. Craven, who was involved in the USS *Sturgeon* submarine disaster, was there.

INTERVIEWER: Was that John Craven?

MR. CULPEPPER: Yes. John Craven was there. He was involved. He had very capable people working for him. The problem, apparently, was in the shipyard. When they built SeaLab II, I had people there who monitored everything the shipyard did. When they saw anything that was not according to plan, they had it redone. On SeaLab III, they didn't do that. Now, as bad as it was leaking, my question is, did they pressure test it? We pressure tested SeaLab II. I don't know.

INTERVIEWER: Now, the penetration was on the top in SeaLab III? Is that correct?

MR. CULPEPPER: I think they had something on the top. Yes.

INTERVIEWER: Do you think that contributed to the rapid loss of helium?

MR. CULPEPPER: Well, I'm not sure it contributed, but it wasn't the primary problem. Bob Porter was involved in the inspection of the habitat afterward, and he told me that there were stuffing tubes in which the components were incorrectly assembled. There were some that had silicone rubber in them instead of the packing gland they were supposed to contain. There were some that didn't have any packing at all in them, and there was a report written containing that information. I managed to get a copy, even though distribution of the report was barred. Dave Haswell worked on the report and managed to get me a copy of it. I had it until one day when

Captain Bond was still in Panama City. In fact, he had an office in Building 49, where my group was. George came in and asked if he could borrow my copy of the SeaLab III report. He said, "There's some things in there I'd like to look at." I said, "Sure, Captain." That was the last I ever saw of it, and then, they planned to tow the habitat out to sea and scuttle it but apparently didn't have funding to do that.

We were allowed to go and take out some of the equipment that we had installed in it. Bob Porter, I believe, and I went out. It was sitting there in the shipyard, locked. We got it open and got our stuff and left, hearing later on that it was scrapped. Now, SeaLab III was a much longer project, obviously, than SeaLabs I or II.

INTERVIEWER: Was that because the attempt was in 1969?

MR. CULPEPPER: Yeah, but it was like three years. Like I said, there was a lot more money and people involved. But that's probably all that I can come up with. We did some things there that we hadn't done before, such as the carbon monoxide burner.

INTERVIEWER: Now, they didn't have those on submarines already? Is what you developed is what they use on subs now?

MR. CULPEPPER: I don't know, but what works on subs won't work in a helium environment at 600 feet.

INTERVIEWER: I see.

MR. CULPEPPER: You've got one atmosphere of air in the submarine. Ray Bentz designed that unit. I can't remember exactly the details of that design now. But some of that unique stuff that we had put in, we were able to go out and retrieve for posterity. But that's probably enough of SeaLab III.

INTERVIEWER: This was 1969.

MR. CULPEPPER: Yes. We developed a heater scrubber unit for the MK II Deep Dive System PTC.

INTERVIEWER: Now, was that a direct result of the SeaLab III attempt, in which the divers were so cold?

MR. CULPEPPER: Yeah. I'm sure it was because it was funded by PMS 395. Those units worked well and used lithium hydroxide for the scrubber. We had some newly developed electrical heating elements. They were thin, flexible, plastic, laminated heating surfaces that could form in a circular configuration inside the scrubber and would heat the air coming through. For the divers, we developed a hot water system in which we put a manifold on the outside of the PTC. It was surface supplied with hot water through a well insulated hose. There were quick disconnects for three diver umbilicals. We developed a helium speech unscrambler that was significantly better than most of those in use. The Marconi unscrambler was about the only one that was close to it. We never evaluated the two, one against the other, but ours worked well. One of the physicists at the Navy Base designed it. He was sort of a whiz. He held a lot of patents on things that he had invented. He used what they called a 'bucket brigade principle,' which just chopped little segments out of the speech and then put it back together. It was so good that you could actually understand the speech much better and even identify the person speaking by the sound of his voice. At one time, they had some problems with one of the Marconi units. We sent this guy and another electronic engineer out to the west coast on a weekend to fix it for them.

INTERVIEWER: Can you remember his name?

MR. CULPEPPER: He was Clell Dildy. He died four years ago. He was the kind of guy that just wouldn't take a mundane job. He wanted a challenging task or he wasn't going to fool with it, and he was really good his job. I gave a copy of the unscrambler design drawings to Taylor Diving and Salvage for its own use. Did you ever know Brian Barrett? He was an English exchange officer here at the Navy Base back during the time that Jim Bladh was his counterpart in England with the dive unit over there.

INTERVIEWER: I think I do.

MR. CULPEPPER: Yes. He was the project officer for the MK 14 when they first started.

INTERVIEWER: Yes. I do remember him.

MR. CULPEPPER: I was the funds manager for it. I ran into him over at the oceanology symposium a couple of weeks ago. He's now an American citizen and working in this country. We had the MK 14 push/pull system, on which Ray Bentz worked. We also had the surface-supplied MK 12 during the same time frame. Lieutenant Barry Ridgewell, a Canadian exchange officer, was the MK 12 project officer.

During SeaLab III, in 1967, they had accidentally dropped the PTC and had some long-term down time for repairs. I came back to Panama City and was assigned responsibility for preparing the design definition document for the OSF, or Ocean Simulation Facility. I got that started, both the design requirements document for it and got it through NAVFAC.

Berry Cannon worked with me on that. He and I actually served on the selection board for the A&E architect with NAVFAC, which was unusual. They normally did not allow the customer to be involved in that process, but with the uniqueness of this project, they felt like we should be involved.

INTERVIEWER: Was that during the time when Jack Tomsy had said that SeaLab II,,,

MR. CULPEPPER: Oh, yeah. They were already on the scene out there.

INTERVIEWER: In the meantime, then, you were then working on the OSF?

MR. CULPEPPER: Yes. That was in the April or May time frame that we did the design definition document. In June, we wrote the design requirements document. It was then that George Combs, a good friend and outstanding mechanical engineer, also an Auburn graduate, was being phased into the effort in order to continue with it when I went back out to SeaLab III.

INTERVIEWER: That was 1967, you said?

MR. CULPEPPER: Yes. Later that year, in September, maybe, SeaLab III started up again. I turned the OSF project over to George Combs. We had already picked the A&E for the OSF and we had gotten it off and running. George picked it up and took it through design, building construction, and chamber fabrication and installation. We established a design review committee not only to closely monitor the design process but also to involve all the naval activities that were involved in diving.

INTERVIEWER: Such as medical research?

MR. CULPEPPER: Yes, like MRI, the experimental diving unit, OOC, and the folks on the west coast, Submarine Development Group One. That was Captain Bill Searle. Walt Mazzone was out there, and Captain Bond was at Panama City. Then, we had Hunter's Point involved. We had the someone from the University of Pennsylvania, an electrical engineer consultant, there. Representatives from the David Taylor Model Basin, with a new 10,000 psi chamber, and the Marine Engineering Lab, with several lower rated chambers, were also members. We had gotten the University of Florida under contract to help in the heat transfer and thermal insulation

problem areas. We involved everybody we could think of because there was so much opposition within the diving Navy to locating the OSF in Panama City.

INTERVIEWER: Was there opposition to building the OSF?

MR. CULPEPPER: No. It was opposition to locating it in Panama City. It needed to be in San Diego, but we had Bob Sikes as our Congressman.

INTERVIEWER: That's interesting.

MR. CULPEPPER: When we had critical design review meetings, most of the Navy people didn't show up. They didn't want to be connected with it. George Combs and I took the results of the meeting and went to San Diego. We sat down with Walt Mazzone and discussed it with him. Then, we went up to Hunter's Point and discussed it with them. We went to the experimental diving unit. John Harder was CO there then. Conveniently, he was out looking for a hydrogen bomb in Spain. We got to talk to a civilian gentleman named Black. I.D. Black was the only guy to whom they let us speak. We went to OOC and did get an audience with Captain Searle, who agreed,, "Yeah, if you guys can get it built, the Navy will probably use it, in time, but we don't think that's where it ought to be." Anyway, we managed to get some participation as the thing went on. That was an interesting time. NAVFAC just didn't do that sort of project. They didn't build research facilities, but we were fortunate enough to have a very astute project manager from NAVFAC by the name of John McNeely, who became very interested in the project. He read everything he could get about diving and saturation diving, and on and on and on. Had it not been for him, it would have probably been a miserable failure.

INTERVIEWER: Who was funding the planning stage of the OSF? Where was the funding coming from?

MR. CULPEPPER: I believe we may have had some funding from the director of Navy labs or SecNav. At that point in time, there wasn't a lot of planning. It was a military construction program. Congress was providing the money, and that became available as soon as we picked an architect and engineering contractor and developed a firm cost estimate. SecNav's guy was directly involved. We had all of those people on board, and we had our first meeting at Carderock. We went there primarily to get to their input and see all their chambers, and then, we went over to tour the Marine Engineering Lab in Annapolis, too. Our marching orders from the director of Navy labs were to go to the A & E contractor, sit down for a week and come up with a firm, fixed price for this project.

When I got the project, it was estimated at \$2.2 or \$2.5 million. Our public works people at the Navy Base had been sort of handling it at that point in time. Where they were getting the money, I don't know, but back then, it was pretty easy to come up with unappropriated funds from one source or another. Anyway, George Combs and I went up to the A & E, Sanders and Thomas, in Pottstown, Pennsylvania. We spent a week and came back with a price of \$10.4 million, and that was what started it.

INTERVIEWER: I wasn't aware of the resistance to the OSF. If it weren't for the OSF, I don't think the dive school would be here.

MR. CULPEPPER: I know, but that was the whole thrust. The effort was to bring all Navy diving to Panama City. That was Tom Odum's dream and it worked. Commander Charlie Hedgepath, as commanding officer of the Experimental Diving Unit, stated in a meeting that he would never move to Panama City. That was the kind of opposition we had. Like I said, we had Bob Sikes. He got the money appropriated and they came to Panama City.

Even after it was built, in place, and online, we had a meeting here. I don't now remember exactly the purpose of the meeting, but we had the meeting in the conference room on the third deck of Building 110. It had something to do with diving, and we had the model of the OSF out in the hall, outside the conference room. Captain Boller and I were standing there, looking at the model, and he said, "Bill, what would it take to move this to San Diego?" I said, "Captain, it would take a darn big barge." That was the end of that conversation. Interestingly enough, although we had intended the OSF to be operated by Navy base civilian personnel, as soon as it became operational, the EDU was there to take it over.

Anyway, that was the OSF. During this time, Charlie Noble was developing the hydrospace lab at the Navy base that has served as a test facility for many dive system systems and components, including some that were earmarked for the OSF. When we first started pressure testing diving systems and components, we were very limited in facilities. We had to go to other facilities, such as those at Duke University.

Along with Ed Sharp, we developed the gas analysis lab and hired two chemical engineers, Al Purer and Glen Deason, from Amarillo, Texas, to increase our capabilities in that area. During this period, our group was involved in many efforts. We supported the MAKAI dive in Hawaii by providing consulting to the project engineer in all areas of design for the Aegir habitat. We provided diver communications and physiological monitoring systems, diver umbilicals, and diver hot water heating. We provided design, fabrication, and installation of diver communications, physiological monitoring, and heating systems for the ASRs USS *Ortolan* and USS *Pigeon*. I provided consulting and design review services to the University of New Hampshire in the design of their undersea habitat, EDELHAB. I also provided engineering

and operational support to the SeaBee commanding officer, Commander Frank Looney, during the initial phase of Tektite I in Lameshur Bay in the Virgin Islands. Wally Jenkins and I, in conjunction with Commander Ed Whittaker and Captain Bill Spaur, of the EDU, wrote Appendix G, Saturation Diving for Deep Diving Systems, to the *U.S. Navy Diving Manual* in 1972. Bill Spaur commented to me a year later, saying that no changes had been made in the first year. Then, we got involved in the MK 14 Mod I. We managed to get, in spite of resistance from higher management, the job of logistic support for 395.

INTERVIEWER: It's been a big project.

MR. CULPEPPER: Yeah. It's dying away now, but it was a long term, well funded effort.

INTERVIEWER: You retired from the Civil Service in 1978?

MR. CULPEPPER: Yes. At that time, I had been out of diving for about three years, I guess. I was transferred because Tom Odum and I were having problems, so I went into the Amphibious Warfare Division. I worked on COTS, or Containers Over The Shore, a project for evaluating the use of heavy lift construction cranes to offload containerized cargo at sea for transport into a beach head to support amphibious landings. This effort included the evaluation of crawler cranes with lift capacities of 200 to 300 tons. We tested them in various configurations, including tilted left or right at angles up to six degrees and instrumented with many strain gages, accelerometers, potentiometers, position sensors, even inertial platforms, and high frequency data analysis and recording systems. When I retired from NCSC, the COTS Project Manager in Washington, D.C., had me hired for three years to continue with the project. We negotiated, and I left the Navy base on Friday and got on a plane Sunday, going to work on Monday. I worked with EG&G for about two years until the COTS project was completed. I worked there until

Columbia Research came looking for somebody to take over the engineering group there, and I worked there for about nine years. During that period, we supported the MK14 Mod 0, MK14 Mod 1, SEAL Delivery Vehicle overhauls, and a number of other diving support tasks. After having difficulties in communicating and working with a new manager, I began looking for other employment.

Fortunately, Lockheed-Martin came along, wanting to open an office in Panama City. They were going to compete for the Navy base test and evaluation support contract. They offered me the opportunity to manage the office for them. They were not successful in winning the contract but had some delivery orders in place, which supported three to five employees. I had three years of work with them before things ran out. During that time, we supported the conventional dive system by maintaining the recordable evidence files, and preparing the integrated test plan and test procedures. I became involved in an effort to provide colder water test capability for the Ocean Simulation Facility. PMS 395 wanted to perform manned tests at a temperature of about 28 degrees.

After a few months of effort, we came up with a ten million dollar price tag, which was what the OSF cost in the beginning, and 395 decided to give it up. As a result, the effort was canceled and Barry Miller called me and said, "Bill, I need to get my money back." I said, "Well, how long do I have to shut it down?" He answered, "How about a week?" I said, "That would be nice." I called my boss, George Lewis, in San Diego, and told him. He said, "What are you going to do next week?" I said, "I'm going to get my resume up to date." That wasn't a problem.

Then, I went to Analysis & Technology, which had the Navy's Diving and Marine Engineering Contract. They said, "Come on down." I said, "Well, I've got two weeks of leave I can take off. I was able to take a week of it before they called me and told me to come to work." There, I was involved in a number of interesting and challenging projects, including the design of certain subsystems for a proposed underwater ship husbandry work boat, like an electro-hydraulic system drive for underwater hydraulic tools and the design of a hydraulically-driven diver umbilical winch. Also included was a lightweight diver air supply rack, including system piping and control console. The work boat effort was dropped after the first year, but the air storage rack design was picked by up OOC and funded to develop a new flyaway dive system. Marty Sheehan was the Navy project manager. He felt that he could maintain better control and minimize costs by contracting the effort to Analysis & Technology. Because of that, the Flyaway Dive System, FADS III, went through critical design review in one year, at a cost of just under one million dollars. After the completion of the FADS III design, the decision was made to develop a mixed gas system to be designated the Flyaway Mixed Gas System, FMGS. This system was designed, fabricated and approved for service use. Have you ever seen that system?

INTERVIEWER: Yes. I have.

MR. CULPEPPER: It's neat. It has storage racks that have nine composite cylinders with air and helium at 5,000 psi and oxygen at 3,000. An air rack has 8700 cubic feet of usable air in it and weighs about 3400 pounds. It's all aluminum and rigged for crane or fork truck handling. The nine cylinders are interconnected, using Synflex HP hoses. The primary bank has four cylinders, the secondary at three, and the third bank, two. Should the situation require, the

number of cylinders in each bank can be varied. For further flexibility, the control console is connected to the storage racks by fifty-foot HP hoses.

INTERVIEWER: Now, OOC developed those for remote areas?

MR. CULPEPPER: Well, so far, only three mixed gas systems have been built. One system has been used by MDSU 2 for recovery efforts on the GRAPPLE and on the leased WOTAN barge in the USS *Monitor* recovery effort. The other two are installed on the YDTs at the Deep Sea Dive School. The system is so flexible that Analysis & Technology's Dale Colemere spent two years writing the failure modes, effects and criticality analysis, which fills two three and a half inch binders. We designed the control consoles, the whole nine yards, and they're all portable. We did the shake and bake tests at the National Aeronautics and Space Administration test facility at Huntsville, Alabama. The shake test opened a few tubing joints, but they were corrected on the spot. The most nervous test was when they dropped the air rack, charged to 5,000 psi, 18 inches onto the concrete floor. I was, of course, standing behind a post and too concerned. We had gotten Bobby Hughes, at the Navy base, to do a finite element analysis on the structure, and I had to go back in and beef it up a little bit. It didn't even dent. Well, that was my swan song, I guess, because it was the last significant dive project I had.

INTERVIEWER: You've been involved in an awful lot of things. You've seen an awful lot.

MR. CULPEPPER: Yes. I have been very fortunate to have been in the right places at the right times and as the good projects came along.

INTERVIEWER: Is there one particular thing that you think is the most significant achievement in the last fifty years in diving?

MR. CULPEPPER: SeaLab.

INTERVIEWER: SeaLab?

MR. CULPEPPER: It was where saturation diving started.

INTERVIEWER: Thinking back on your career in undersea technology, if all the barriers had been removed and you had been given absolute authority to do anything you had wanted, would you have changed anything?

MR. CULPEPPER: I would have changed a few symbolic things, I guess, but nothing major.

I was, more or less, a hands-on working engineer. Now, I had a brief tour of three years during which I had the ocean engineering division out there. There, again, we were doing all of the saturation diving development work for the base, primarily PMS 395, at that time. I would not have been eliminated from SeaLab III, hopefully, if I could have saved Berry Cannon's life.

Hopefully, the project would have been run differently. The habitat wouldn't have leaked.

INTERVIEWER: What would you have done differently with SeaLab III?

MR. CULPEPPER: I would have had people out there on the job to monitor the shipyard's work and make sure that things were done correctly because we had a lot of experience from SeaLab II. We knew the shipyard workers were not experienced in doing that kind of work. One of the things, as an example, was with one of the people in the design division. I had sketched out the scrubber/dehumidifier unit, and I had 12 lithium hydroxide carbon dioxide canisters. They were on the bottom, at floor level, and it was an updraft system. I had the filters above, which used activated charcoal as a multi-purpose filter for hydroxide dust, odors, and other atmospheric contaminants. I had very carefully scaled the volume available and had specified the volume of charcoal to be included. Above the charcoal was the DH heat exchanger. The guy doing the shop drawings to fit this into the habitat was a short little guy. He said, "There's not enough room."

I said, "Sure, there is. I've got it sketched out and scaled." He complained that he was having trouble getting that much in. He asked, "Why do you need so much charcoal?" I said, "Well, I put the carbon dioxide canisters in there. I then put in the DH core. What was left, I filled up with charcoal." He asked why. I said, "Well, I really don't know how much charcoal is going to be required for forty-some days of operation with ten guys in there." I asked, "Do you know?" He said no. I said, "Well, that's how much we are going to put in there." But they do most things by the book. They don't think. Well, they think, but they're just not used to doing research and development-type work. As it turned out, apparently, the charcoal filter worked pretty well. I don't know whether I had too much or too little, but I don't think that I had too little. I did have some literature on charcoal filters for restaurants, but that's totally different. You have cigarette smoke, grease, and all kinds of stuff in a restaurant. But I got some feel for a human quantity.

INTERVIEWER: You were blazing a new frontier.

MR. CULPEPPER: Exactly. It was fun. It was fun, looking back. When I was there, it wasn't so much fun.

INTERVIEWER: For the first half of the century, the U.S. Navy really was a world leader in diving. Since that time, many Navy divers had been leaders in the commercial diving field.

Currently, neither of these facts seem to be true. Do you have any thoughts on that?

MR. CULPEPPER: I don't know. From my experience, one of the problems that we had back then, in the days of SeaLab, developing saturation diving, was that the Navy could never really come up with a solid mission requirement. Therefore, after SeaLab III, there was little effort or interest for a number of years. Commercial folks in this country have far exceeded anything the Navy has done on a volume basis, anyway. A while back, I went to an ADC symposium. It was

probably three years ago, and I was amazed to hear that they were routinely working at 1200 to 1300 feet. I didn't know that. I knew it was possible. The oil companies have missions at those depths, but the Navy doesn't.

INTERVIEWER: Now, the Navy's saturation capability is very limited right now, very limited.

MR. CULPEPPER: Yes.

INTERVIEWER: Is this a mistake, do you think?

MR. CULPEPPER: I don't know.

INTERVIEWER: There's actually talk about leasing a commercial system for the *Monitor*.

MR. CULPEPPER: Yes.

INTERVIEWER: Are we missing out?

MR. CULPEPPER: I think we are. I think we ought to have a limited-depth capability in saturation diving, to 600, 800, even a 1000 feet, or something like that. I don't think we need to go to the extreme, but it's something that, if we needed it, could be accomplished in a relatively short period of time, I think. We know the technology. It's just a matter of equipment.

INTERVIEWER: What do you think we should be looking for in the future?

MR. CULPEPPER: I really can't answer that. I have not been involved in any of the things that are going on now. I know there's some effort, as far as a rescue capability. I think that's important. I have trouble putting a value on it because I don't know what the future undersea scenarios will be. There have been so many unsuccessful things tried in the past, like rescue systems, the *Ortolan* and the *Pigeon* and deep sea rescue vehicles. The deep dive systems, MK 1 and MK 2, were never much utilized for lack of need. The point is, how many submarine accidents do you expect to have? There doesn't seem to be much possibility of developing a

viable and affordable rescue system for use in the deep ocean. Therefore, I think we should evaluate the need and viability of rescue systems for shallower depths, to maybe 1000 feet.

INTERVIEWER: Except that in recent years, I mean the total warfare has become much more important.

MR. CULPEPPER: Well, that's true. Now, you're looking at a different class of submarines, the smaller, shallow water boats. But it is for somebody else to determine what degree of capability we need.

INTERVIEWER: Recently, I've been reading a lot of books on the submarine disasters in the early 1900s, like the *S-51* and the *S-4*. Of course, until then, it was just an accepted risk.

MR. CULPEPPER: Yes.

INTERVIEWER: The idea of having a way of escaping was just not important.

MR. CULPEPPER: Again, McCann came along.

INTERVIEWER: Mumsen also helped. Of course, the *Kirsk* demonstrated that there is a need.

MR. CULPEPPER: Yes.

INTERVIEWER: Well, you've had a wonderful career to reflect on. That's for sure.

MR. CULPEPPER: The interesting thing about my career is the fact that it's been so widely ranging. I've worked on dive systems. I've worked on ships, mine and torpedo countermeasures, and big 200 and 300 ton cranes. I helped break a 300 ton crane one time. It only took three months and \$80,000 worth of parts to fix it. We put cranes on ships and offloaded cargo. We spent 42 days and nights in Green Cove Springs, testing a crane. Anne and I celebrated our 25th wedding anniversary in Green Cove Springs. She took off from work, flew down there, and we had dinner with seven other guys for our anniversary. That was a bear.

INTERVIEWER: Well, thank you for sharing your experiences.

MR. CULPEPPER: Well, you're certainly welcome.

## U.S. NAVAL SERVICE OF WILLIAM R. LEIBOLD, Sr.

The summer of 1940 was coming to an end and my impending return to high school studies was not something I looked forward to. Following completion of the eleventh grade, I had no sense of real accomplishment and completion of my senior year would not, in my opinion, have been a challenge.

My interest in submarines led me to the Naval Recruiting Office in downtown Los Angeles, CA. I was given a written test and advised that parental permission was required in that I was not yet eighteen. My parents opposed my leaving school to enlist but I was able to convince my father that it was the route I wanted and he gave his permission. About three months elapsed before I was notified to report for further tests and a physical and this was followed by my enlistment on 30 November 1940.

Recruit training was completed at the Naval Training Station, San Diego. While on one of the few "liberties" given while in "Boot Training" I went to the fleet landing to watch the "old salts" coming ashore. A strange little boat made the pier and discharged a group of sailors, the cox'n saw me eyeing his boat and invited me to ride out to his submarine. His sub was the Dolphin (D1); I spent the weekend on board and was even more convinced that submarine duty was for me.

I completed boot training in February 1941 and received orders to ComMineBatFor in Pearl Harbor. Transportation to Pearl was via the USS Relief, a hospital ship. A large draft of recruits was being transported and was kept busy in the deck divisions, chipping and painting as they rolled and retched across the Pacific. Arriving in Pearl, the Relief berthed at 1010 dock where the recruits were assembled. There were a number of ancient ships at berths nearby and the group I was in was marched to them. A chief then began calling out that he needed so many men for the various ships. When he called out "I need three men for Pruitt", three of us standing together stepped forward and were directed to our new home, USS Pruitt (DM22), last of the WWI four stack destroyers. She had been converted to a light minelayer and was undergoing upkeep at the shipyard. We were directed to place our gear (hammock, mattress, sea bag) on deck until we were assigned to a berthing space. A petty officer took me in tow and put me on "fire watch" for a shipyard welder. The welder completed his job and left, not knowing any better, I continued standing watch until a petty officer came by and asked "what are you doing here kid"? I informed him that I was the fire watch, when he stopped laughing he introduced himself, Fergus, GM2c. He then saw to it that I got some chow as the evening meal had already been served and got me squared away with a bunk. The next morning, we were introduced to the executive officer who advised us,

amongst other things, that we would be allowed to wear dungarees, while the Pruitt was in the shipyard. Dungarees were available in the ship's canteen and we could pay for them on the next payday. At this time, dungarees were only authorized for engineers and side cleaners.

I was assigned to the deck force and promptly started submitting special request chits for assignment to submarine school. After my second or third request, my division officer told me to knock it off, I had to have a year at sea and be Seaman 1c to be eligible. At that time, advancement to Seaman 2c from Apprentice Seaman was automatic after four months service. I completed the training course and practical factors for Seaman 1c in short order and spent \$8.50 of my monthly pay of \$29.40 (after insurance & medical deductions) for a Knight's Modern Seamanship. I spent much of my free time with that book and passed the seaman exam as soon as I was eligible. This was quite a pay boost to \$54. per month! The Navy was expanding, consequently, advancement opportunities were increasing and required time in rate was being decreased. Many of the old timers were not pleased seeing youngsters pass an examination for advancement on their first try and then actually being advanced regardless of vacancies.

One has to understand the era and circumstances: Our country was emerging from many years of depression, the Navy was expanding both in men and ships, preparing for war following years of limited funding and advancement opportunities. In Pruitt the crew was primarily composed of "old timers" who had kept their ship going during those austere times, it was understandably difficult for many to accept the rapid changes taking place. It was easy for me, I didn't know any better. The Bureau of Navigation (later BuPers) published a small booklet of "Circular Letters" (later notices/instructions) periodically. Information contained therein was not generally made available to enlisted personnel but our Yeoman showed me a letter calling for volunteers for submarine duty and I promptly submitted a request chit for submarine school. After several chits and no action, I was ordered to report to the Executive Officer who wanted to know where I got off putting in all the chits. I told him that I was requesting submarine school in accordance with the Circular Letter calling for volunteers. He informed me that I had no business reading circular letters; his policy was not to train men and then transfer them to something like submarines and I was not to put any more chits in. Bah Humbug!

I decided to strike for Quartermaster and spoke to the Chief Signalman about getting into the bridge gang. He was encouraging and told me that if I did a good job, he would let me put a course in for third class after shipping over on my second cruise! This seemed to be too far off so I spoke with the Chief Bosun's Mate who told me he would put me up for third class as soon as I was eligible. I promptly went to work on a course for cox'n.

Pruitt was a good training platform and I became a competent seaman while serving in her. This was the "old Navy" indeed. The anchor windlass was steam driven but, we broke the anchor out with capstan bars and "Swedish Steam" from six deck hands on a quarterly basis, just in case. We also hoisted the whaleboat manually periodically. Our refrigeration consisted of an icebox on the main deck, above #2 fireroom and when the ice melted, which did not take long, so went our "fresh" stores. I was always intrigued with part of the ships armament of six cutlasses that were carried by the officers during our Annual Military Inspection; the blades were meant for business and large brass knuckle guards were fitted on each cutlass.

We operated out of Pearl Harbor laying practice mine fields off Lahaina, Maui and .general operations such as underway refueling/replenishment and gunnery practice. Quarters for muster and inspection was held on weekdays followed by calisthenics', Captains personnel inspection was held on Saturday morning when in port followed by liberty for the non-duty sections commencing at 1300 and expiring at 0700 the following Monday. I can only recall two married men below CPO and liberty parties were not large.

December 7, 1941 brought an abrupt change to our daily routine. Pruitt was at Berth 18 in .the Shipyard, undergoing overhaul. The duty section was on board with the remaining crew berthed at the receiving station barracks. All ammunition/fuel etc had been removed from the ship. A shipmate and I had just returned to the barracks after breakfast and were discussing what we would do on this sunny Sunday when I thought I heard an explosion. I went over to the window (we were on the second deck) and looked out just in time to see a plane, at low level, passing by. It had a large red "meatball" on the fuselage! I yelled out "it's the Japs" and headed for the stairway with several shipmates. We double timed it back to our ship where the duty chief told us that the duty section could handle damage control and directed my group of four to go to the Pennsylvania (BB38) where they needed men. Pensy was in the main dry dock with the destroyers Cassin and Downes. As we crossed the brow, strafing was taking place and the OOD directed us to take cover in the Marine's compartment off the quarterdeck. I was sent to a 5"25cal gun on the starboard side where the gun captain put me in the ammo train. We fired many rounds, there was a hit just aft of the gun I was on and a shipmate from Pruitt was killed. The two destroyers ahead of us took hits and were both total losses. It was a busy morning and as the regular crew had largely returned to Pensy, men such as myself were .released to return to our ships about 1300. I had been hit with a small piece of shrapnel in my right hand, it was removed by our Chief Pharmacists Mate and I kept it as a souvenir but lost it somewhere along the way, possibly on Tang.

Back on Pruitt, we went into a two-section status and started loading ammo and supplies while the yard birds worked to put us back together. We were given instructions in a password system that had been instituted. I had the 20-24 watch and when relieved, two shipmates and I headed for the barracks, it was starting to drizzle and we could hear someone walking ahead of us. Suddenly, "Halt, who goes there" rang in the darkness, the three of us froze but the person ahead kept walking. A shot rang out and the guy ahead of us stopped walking. A marine was patrolling the area and after he checked us out, we all went over to the guy who had been shot, he was dead, a casualty of war. One of my shipmates was a very black mess attendant named Lonnie Joe Nelson, when the shot was fired he grabbed my arm and exclaimed, "is you dere boy, is you dere boy"? Later he told me that he didn't know who had been shot but thought it had been one of us. Lonnie Joe was a few shades lighter when we reached the RecSta that was under construction. We mustered in at what later became the Navy Exchange. Groups of men were gathered under signs with the name of their ship, mostly battleships, It was rumored that the water supply had been contaminated so if you were thirsty you were given half a cup of coca cola.

As soon as Pruitt was ready for sea, we were put on offshore patrol, then the entire division went to work laying minefields. I was still pursuing submarine duty and had lined up at swap with a man on the Argonaut. My exec finally gave in with the provision that he would approve the swap when we returned from an upcoming operation. This operation took us to the Aleutians for the Attu/Kiska occupation. Following this, we tangled with a very severe storm. Pruitt suffered considerable damage including the parting of all stays to the 97' wooden foremast. Without support, the mast was really unstable and looked as though it would come down. I hauled lines up the mast and secured them. My good shipmate "Chick" Triplett, GMlc was below feeding the lines to me. It was cold, everything was coated with ice, and the ship was rolling heavily so working was difficult. After we got the mast secured we both went below to try to get warm and a messenger (Pruitt had no loudspeaker system) told us we were to report to the captain on the bridge. Now what had we done to get into trouble this time! We went right up and the captain and exec were waiting for us by the flag bag. The storm had either abated or the ship had reached the safe semi-circle of what I suspect was a typhoon. The captain told us to stand at ease and said, "you men may very well have saved the ship!" He looked at me and said "Leibold, as of now you are advanced to Bosun's Mate First Class," he turned to Chick and advanced him to Chief Gunners Mate. The captain then stated that he would look into recommending us for a commission, then looked at me winked and said, "Leibold, you can have your choice of duty!" Chick and I were fair-haired boys for the rest of that trip.

We went into Dutch Harbor for repairs, then on to San Francisco. Upon arrival, I was told to stay on board until the captain returned from a meeting. That evening, I was summoned to the quarterdeck where the captain told me that I could pack my bag, I would have orders to submarine duty by the next morning. The orders came in that night by dispatch, I still have a copy of the dispatch that read in part: "Transfer W.R. Leibold BM 1 C to Commander Submarine Force Pacific Administration Mare Island Calif for assignment to submarine duty." My life on Pruitt had come to an end and from what I could gather, Pruitt was to be inspected to determine her fitness for continued service. The storm had taken a toll on that fine old ship. So, on 8 July 1943, I was finally on my way to submarine duty. I reported in at SubAd, Mare Island and was promptly given a job as "Master At Arms" and told that inasmuch as I had been at sea for some time, I would have a tour ashore! This was not in my plans! I snooped around the shipyard and found the Tang being readied for commissioning; this was going to be my boat one way or another!

I was given leave and went to visit my parents and especially the girl I had gone to school with, Grace Fiskin. I had proposed to her while I was still on Pruitt but we had no firm plans. We were married in North Hollywood, CA and enjoyed a short honeymoon in Laguna Beach, CA. I returned to Mare Island and Grace soon followed. We lived in a hotel (we could not afford) then moved in with another couple in Navy housing for a short while. A shipmate at SubAd, Bob Barbee, GMlc who was waiting for assignment was also in need of housing as he and his bride were in a rooming house. We teamed up and started hitting the Navy housing office twice a day. Finally, the lady in charge at the office notified us to come in. She raked us over the coals for bugging her so consistently, we figured that we would never get housing when she softened up and said, "if you two promise never to come in here again, I have a three bedroom unit you can share." We had a home! It was not furnished and we had no furniture but our brides went to Sears and bought bedroom sets and Bob and I bought a used table and chairs and we set up housekeeping. Grace and I had acquired a 1938 Ford coupe and the four of us had some good times together going to San Francisco for nightlife.

On occasion, I would make a guard mail trip to submarines in the Bay Area and on one trip to the Grayback (SS208) the Captain kidded me about the soft job I had. I told him it was only temporary, that I would be assigned to a submarine soon. He replied that he would take a Bosun's mate on Grayback. I thanked him and said that I was going to a new boat, the Tang, under construction at Mare Island. An officer nearby, taking all this in asked if I had orders to Tang and I replied "no sir, but I am going to serve on her." He then introduced himself: Lt. Frazee, prospective executive officer of Tang! I've forgotten how I wiggled out of that one but about a week later, I was directed to report to the Tang office

and when I arrived LT. Frazee introduced me to LCDR O'Kane, the prospective commanding officer. After a brief "quiz" session, O'Kane stated that he too had served in Pruitt while it was still DD347 and that he would take me on Tang!

Grace had gone to work doing clerical work at the shipyard administration and expected me to be ashore for a while. I told her that I had been drafted to submarine duty and would be leaving shortly. Bob got orders to Tilefish and planned to take his wife, Gena, to their home in Texas. This worked out for us in that Grace did not have a driver license and they drove her to Los Angeles.

Tang and company headed west in January 1944, we operated out of Pearl and Midway making five successful patrols. In July 1944, I was advanced to CBM. Unfortunately, at approximately 0230, 25 October 1943, during a surface attack in the Formosa Straits, our last torpedo ran erratic, circled and hit Tang, quickly sinking her. Of nine men on the bridge, three, including me, managed to stay afloat for approximately eight hours. One officer LT Savadkin, in the flooded conning tower, made a free ascent and survived. Thirteen men attempted escapes from the forward torpedo room starting about four hours after the boat was on the bottom, five men survived. Of the nine survivors, four are alive today (3/03). 78 fine men were lost in Tang. Even though it was very dark, the erratic torpedo could be seen, porpoising and curving back on the port side, maneuvering to avoid failed and the torpedo struck near the maneuvering room/after torpedo room. On impact, the stern started to drop slowly and I could see the water covering the after deck, suddenly Tang went down by the stern and I went down for quite a distance, I felt a bump or explosion, then started up to the surface where the bow was out of the water, at an acute angle, I tried to reach it but the current was too strong and I slowly drifted away. I heard voices, Jones and Rector, but they also drifted away. I recall first tossing my binoculars, then got my jacket and shoes off. I took my trousers off and after tying the legs, tried to inflate them for flotation but no success so I tossed them. I stayed afloat by treading water and floating for some time and suddenly became aware of something splashing and sputtering nearby. It was Floyd Caverly, RTlc and we stayed together figuring we would head for islands off the china coast at daybreak when we could see them.

Tang had wreaked havoc before going down; the Japanese were picking up survivors from their own sunken ships and I am sure were surprised at finding us. Caverly and I were picked up at the same time by a pulling boat whose Cox'n kept saying "Deutch-ka." Caverly thought the Cox'n figured we were Germans and blurted out "Heil Hitler." As the boat returned to the ship, another man was spotted and it turned out to be our Skipper who was hanging on to what appeared to be a wooden door. I screwed up by saying "good morning Captain, do you want a ride" as we helped him aboard. The Cox'n must *i* have

recognized "Captain" as he had the Skipper come to the stem and sit on a thwart. Caverly and I remained in the bow. When we got alongside what appeared to be like our destroyer escort type ship, the boat was hoisted to the main deck level where we disembarked. Caverly noticed one of the nip sailors had a wristwatch and took his arm to see what time it was, wham! He learned the hard way but knew it was just past 1030. We were promptly bound and made to sit on the port side of the main deck, soon thereafter, LT Savadkin joined us and then Flanagan, Trukke, DaSilva, Narowanski and Decker joined us. We learned later that another man, Chief Pharmacists Mate Larson was also picked up but started convulsing and lost consciousness when the boat came alongside, he was never seen again. I was between the skipper and Hayes Trukke, TM2c who had come to Tang just before this patrol. Following hours in the water, Trukke's excessively long straw-like hair was covering his face. The skipper nudged me and asked who was next to me and I told him "Trukke" to which he exclaimed "was he on my boat?!"

The nip ship (#34 painted on bow) had a number of survivors from the ships we had sunk, some were burned and bandaged and they rightly figured we were responsible of their misery and proceeded to spread the wealth. We were on the ship for three days, confined in their "hot tub" room that was very small and uncomfortable. On the third day we entered Takao, the southern port on Formosa where hoods were placed over our heads and we were loaded into a truck. We spent the night in what appeared to be a warehouse, a very uncomfortable night with our hands tightly bound and our arms pulled above our heads. During the night, we were interrogated, given some water and worked over. The next morning, the hoods were put back on our heads and we were paraded through town, this must have been a real sight, in my case, I had what was left of blue and white striped under shorts and a shirt on. My shipmates were similarly dressed. I could see a little through the hood and there appeared to be quite a crowd surrounding us. Our treatment indicated we were not the most popular kids on the block.

We ended up at a railroad station and were put on a train. The hoods were removed and each of us was given a window seat with a guard sitting alongside. The train ride was actually pleasant, we saw the countryside but every time we pulled into a station, we could see people on the platforms getting food & drinks, none for us. We reached our destination late in the afternoon that turned out to be Kiirun and were bussed to a nip army installation where we were put in a cell that we called the "Kiirun Clink." This place was out of the dark ages, our cell was a large room about two feet above the adjacent passageway. The bars were hard wood about 6-8 inches in diameter, the entrance was small requiring a person to crawl into the cell, a hole in one wall, about .3 'x4' provided access to the head which was a slit in the deck with running water several feet below. The ceiling was high, about ten feet, and there was a barred window at the top of one wall that appeared to be plastered. We were all in the one cell and soon after our arrival nine bundles were pushed through an opening in the bars with cups of hot tea. The bundles appeared to be

wrapped in some sort of leaf and each contained rice and a pickled vegetable. This was the first food We had since capture. Our stay lasted three days and we were fed three times daily.

On the third day, we were loaded onto a bus, each with his own armed guard, we were not bound or blindfolded. The bus was propelled by a charcoal fired boiler of sorts mounted on the rear end and soon after leaving it stalled. Several guards got off the bus, leaving their rifles leaning on their empty seat to push the bus, when it started, the driver failed to stop and the guards ended up chasing it down the road while the remaining guards laughed. When the bus finally came to a halt, the pushers came back aboard and got a good laugh about leaving their rifles with their prisoners. Our destination was the Port where our officers were each put aboard a destroyer, the enlisted aboard a cruiser. The ships got underway soon after we boarded. We (enlisted) were put in a hold with two guards. The hold was loaded with what turned out to be sacks of cane sugar and we were on top of them. It was apparent that we were making high speed. From time to time, nip sailors would enter the hold and after punching a hole in a sack, they would appropriate sugar into little bags. This trip lasted about four days and we arrived in Kobe, Japan on a rainy, cold morning. We were taken ashore at what appeared to be a naval training station and all nine of us were lined up for inspection by a nip admiral. He asked me in excellent English, as I shivered in the cold, if I was frightened and I replied, "No. I am cold." He then said "of course stupid, no shoes" and I figured the old boy would see to it that we were issued some clothing, that didn't happen!

Our next adventure was a train ride; we had a private coach this time, each with his own guard and an officer in charge. We were not bound or blindfold, it was a long ride and we arrived at what we later learned was Ofuna station. It was a cold, rainy night and we were marched down a dark muddy road for some distance to our new home, "Ofuna." Upon arrival, we were allowed to take a bath, were given some worn out clothing and each of us were put in an individual cell. Caverly and I were singled out to follow a guard to the galley where a familiar looking man put a wooden bucket of food, a pot of tea and bowls/cups on the deck before us. No words were spoken until our guard told us to pick the items up and we returned to our building. The guard instructed mostly by hand signals to put the food, which appeared to be a mixture of rice and vegetables, into the bowls, then pour the tea and place a cup and bowl on the deck outside each cell. The cell floor was about one foot above the passageway deck. When this was done, we were directed back to our cells, the guard then proceeded to open each door and the occupant was allowed to take the food and eat. Following our meal, we were allowed to bed down for the night.

Each cell was about 5'x6' and had a tatami mat on the deck. A glass port allowed the guard, who patrolled the passageway, to keep a check on the occupant. We were provided with two blankets.

In the morning, we were fed again and then an American prisoner gave us a rundown on .camp routine in the presence of a guard. The prisoner was Knutson, RM1c of USS Grenadier SS210. We were then herded out of the building to another part of the camp where we were told we would be given a lesson in Japanese. A slight built prisoner was brought out and after a lot of shouting by the nip in charge, the man was beaten senseless. We all thought that he had been killed. We were returned to our cells in what we learned was a building called "Eku." Later we learned that the man that had been so badly beaten was LCDR John Fitzgerald, the Skipper of Grenadier. There were three people from Grenadier at Ofuna when we arrived and they were all transferred to another camp soon after our arrival.

Ofuna consisted of one building that housed the C.O., guards, interrogation rooms and galley, it was "L" shaped and connected to "Eku" where new arrivals were incarcerated. Three additional buildings were in the compound, "niku," "sanku" and a one room structure, "yanku." The entire facility was enclosed with a high wooden fence, eku was separated from the rest of the facility by a high fence.

We were informed early on, that we were not "prisoners of war" rather, we were "captured enemy" and therefore, not covered by the Geneva Convention governing Prisoners of War. Initially, we were kept in solitary confinement and interrogated frequently. The interrogators were always in civilian clothes, spoke English very well and had been educated in the U.S. Although a guard was always present during interrogation, I was never mistreated during the sessions but sure got whacked afterwards.

On Christmas day 1944, several guards came to Eku, opened our cell doors and gave each of us a Red Cross food package. The box was about 12"x12"x6" and contained tins of corned beef, pate', powdered milk, chocolate bars, etc. as well as two packs of cigarettes. There was also a small folding can opener. We were ordered not to open or use any of the contents as we were going outside to celebrate our Christmas with other prisoners and, to leave the packages in our cell. We were taken outside and the gate leading to the other buildings was opened allowing the other prisoners into our compound. This is when we learned that the Grenadier survivors were gone and that the man that had been so badly beaten on our first day in Of una had been John Fitzgerald. I also met the familiar face from the galley on our first night. He was Major Gregory Boyington who I had read about in either a Life or Look magazine during our final patrol. There was a full-page photo of him in the article and this is why he was familiar to me.

We found that all of the prisoners were either flyers or submarine men. There were three people from the British submarine Stratagem, all the rest were flyers. We also learned that in the eyes of the nips, we were criminals, for entering their Empire skies and waters. Following the "social hour" we were returned to our cells and found our packages near empty or gone altogether. Mine was gone. We all did a lot of shouting

and beating on our cell doors, the guard was concerned about the racket we were making and finally showed up with a basket of hot sweet potatoes. He gave two potatoes to each of us.

As time went by, more prisoners were brought in, all flyers captured by the nip navy. Ofuna was run by the UN and supported from the Yokuska Naval Base. As eku filled with the new arrivals, Tang men were released from solitary to do chores in and around eku. Floyd Caverly (AKA "Friar Tuck" )was singled out to do some work for the "kongo- cho" who was equivalent to a Chief Pharmacists Mate. A tall, muscular man who spoke English fairly well and appeared to pull a lot of weight with the "quiz kids" and officers from Y okuska. His name was Kitamura. After a short time, Kitamura wanted another man to do work for him and Friar Tuck suggested me and I got the job. Friar and I did odd maintenance jobs around the camp. One of the flyers brought in was badly burned . and had been bandaged, I was given the impossible task of washing his bandages, both original and subsequent bandaging. Mter washing and salvaging what I could, I would hang them on a line to dry. The flyer, a B-29 pilot by the name of Hunt was kept in a cell in eku. He deteriorated to a point where Kitamura and the guards would not go into his cell due to the stench. O'Kane interceded on Hunts behalf with one of the quiz kids and we were allowed to provide care for him but he died. We carried his remains to yanku, the small building reserved for the dead and Kitamura (a self styled carpenter) made a wooden coffin. Late one night, Hunt was buried across the road from the camp in an area reserved for such things.

Some of the guards would flaunt items from the Red Cross food packages so; we knew there were more in the camp. Friar and I were cleaning the passageway in sanku when we discovered what appeared to be a locked storeroom at the far end of the building. There was no guard in sight so we forced the sliding door off its track and got a peek at what appeared to be stacks of Red Cross packages when a guard appeared at the far end of the passageway. We quickly staged a fight, I hit Friar and he fell against the door, by then the guard was there, broke up our "fight" and raised heck about us knocking the door loose. We hastily got the door back on its track and the guard made sure we finished our work and left the building.

Friar and I were in adjacent cells and were able to communicate when the guard was down the passageway. We felt certain that we now knew the location of the food packages. But how to get to them? Eku was built about 18" above ground and after examining the deck under the tatami mat we agreed that by lifting the floorboards, we could go out under the building, make our way to sanku and go in through the window. The floorboards were nailed down but there was enough space between boards to get ones fingers in and grip the board. Our plan was to loosen the boards and nails, then pull the nails and cut them

off with a pair of side cutters that Friar had "borrowed" from Kitamura's toolbox. Friar did his boards first while I kept watch for the guard, the following night, I did mine while Friar kept a lookout. By inserting the shortened nails in the nail holes, the boards appeared to be nailed down if the tatami was lifted. We now had a means to leave and reenter our cell but we had to be careful that the right guard was on watch.

On our first trip, all went well until we got to sanku, the window had wooden bars but we were able to pull a couple loose. Once inside, we found the Red Cross boxes, they were large and bound with metal straps that we could not budge. It appeared that each large box contained four of the smaller packages. We left, put the bars back in place and got back to our cells, it was well past midnight. The side cutters were needed again if we were to get into those boxes. A few nights later, we made another try, this time with the side cutters. We took two small boxes and switched the large box to the bottom of the stack with unopened boxes on top. The boxes were kept under our cells and we tapped them at night. I found out years later that other prisoners were also getting into the storeroom.

In early April 1945, it all came to a head when all the prisoners were assembled and the Camp Commander (the Mummy) said there were Red Cross food packages missing and he wanted to know who had taken them. We were all worked over but none of the prisoners admitted anything. That night the nip CPO's worked the guards over and I guess they finally figured it was impossible for the prisoners to have gotten to the packages.

Soon after this, all Tang enlisted men, some flyers including Greg Boyington were taken to the POW Camp Omori, near Yokohama. This camp was run by the army and had about 600 prisoners. There were 21 in our group and we were again locked up as a group. We were kept in a room at one end of a long barracks type building, completely fenced. A guard was posted in the room and another just outside the door. We were now "tokobetsu hoyo" or "special prisoners" and were kept in the room about a month when the nip top sergeant told us that we would go on work detail and be given 2/3 of a prisoner's ration of food. This is when we learned that we had been getting 1/2 of what the prisoners got. Most of us had no shoes and pointed this out; the sergeant said he would take care of this. The next morning, there were several pairs of shoes outside the door, loaned to us by prisoners who stayed in camp. We worked outside the camp in bombed out areas clearing wreckage and also dug caves.

We had a guard that we called "Gimpy" who was a civilian that had been badly wounded while in the army. He spoke English and made no bones about his distaste for the war. One day he was talking with an older nip woman, as we worked, she left and then returned, gave him something and he called us all together, handed the item to Boyington with instructions to divide it. The item was a "mochi" something

like a donut; there were 19 of us that day and Greg managed to get 19 pieces cut. The next day, two old ladies showed up carrying a tray of candied carrots for us. Gimpy told us they were concerned over our appearance; we did not look like the paws who wore better clothing and appeared healthy. When we returned to Omori, Gimpy marched us to the commandants building, he went in and returned with the commandant and top sergeant. There was a lot of discussion and we ended up being marched to the bathhouse where we were allowed to get cleaned up, the first time since our arrival at Omori.

Air raids were increasing and that is the only time we were left unguarded, the guards would go to a shelter and we were able to watch the fireworks that were impressive. In June, a group of prisoners, including Tang officers, was brought to Omori and locked up with us. The room we occupied was now full. Additional prisoners were brought in and locked up in a room adjacent to ours. These were all flyers, recently captured; we were able to communicate through the wall, when the guard was goofing off.

I think it was August 9, 1945, we were digging a cave into the side of a hill near Yokohoma, loudspeakers could be heard and about mid-day and from the way the guards acted, something was up. The interpreter told us to bring all tools out of the cave and unstring the lights. I had come out with some tools and was told to sit down and was given a cup of tea by the interpreter. My right foot was in bad shape after a guard had redesigned it a couple of weeks before and the interpreter told me that soon I would get medical treatment. in a hospital Our group was formed up and started the march back to Omori; as we marched a couple of truckloads of prisoners passed us and shouted "the wars over." When we got back to Omori, the guards put us in our room and left us, without a guard. There was a lot of shouting in the camp and some of the prisoners came to our building and told us the war was over but cautioned us to remain in our room and they would stand guard outside the building. Some of the guards were drinking and could pose a problem for us. One drunken nip soldier did try to get into our space but was permanently put out of his misery by top Sergeant Ogura.

Most of the nips left the camp leaving the commandant and Sgt. Ogura. They stayed in their quarters and the prisoners got organized. CDR O'Kane was the senior officer, Maj. Boyington became the Provost Marshall. I was put in charge of a barracks with 103 men, It wasn't long before our planes; Navy and Air Force, were flying over Omori dropping all kinds of goodies. The B29s would drop 55 gal drums, lashed together in pairs, attached to small chutes. I got khaki shirt and trousers and a pair of shoes as did the other Tang people.

At the end of August, a landing party came to Omori under the command of CDR Stassen. He told us that they were there to make arrangements for our evacuation that would take place in the next couple of days.

After looking the place over, CDR Stassen told us to get any belongings we had, he was starting evacuation immediately.

Someone put a tag on me that was stamped "non-ambulatory" and I was taken to a Navy hospital ship (Benevolence) anchored in the Bay. After initial treatment, I went to an LSD (Ozark) also anchored to await air transportation. I ended up at the Naval Hospital, Oakland for a short period, then to Long Beach Naval Hospital where I remained for several months.

I returned to duty and was assigned to the *NROTC* Unit at UCLA. While there, I was advanced to Warrant Bosn. Although the duty was great, it was not for me and I requested a change and was ordered to Mare Island for duty on USS Pelias ASI4, the accommodation ship for ComSubGrp PacResFlt. Grace and I moved to Vallejo, now with our young son Bill. One afternoon, I received dispatch orders to "proceed immediately" to Tokyo, Japan for duty in connection with the War Crimes Trials. I was not enthused over this but the next day Grace drove me down to Alameda Naval Air Station where I got a flight to Japan.

In Japan, I was assigned to the Legal Section, SCAP (Supreme Commander Allied Powers). They had most of the Of una gang in Sugamo Prison and I was out there to provide testimony and assist the lawyers in Of una cases. They required live witnesses for death penalty cases. I did not want to be out there and it appeared that everything was taking too long. I got a ham call back to O'Kane to apprise him of the situation, In a few days, O'Kane showed up and raised a good bit of hell. Things started to move and after some of the trials were completed, I figured it was time for me to leave. I made my departure call on the Colonel in charge of the legal section and he promptly informed me that he had not authorized my leaving. O'Kane was with me and he told the Colonel that his authorization was not required, CornNavFe had endorsed my orders and made travel arrangements. Soon after that O'Kane returned to the States, where he was the Chief Staff Officer for ComSubGrp, PacResFlt, effectively my boss.

In 1948 I received orders to USS Nereus AS 17, home ported in San Diego. We packed up and moved to Chula Vista. Our daughter Ericka arrived the following year. At that time Warrant Officers had their own quarters and Mess, I recall that there were eleven Warrants on board and we led a good life. Nereus and Sperry AS 12 were in two point moors adjacent to the Coast Guard Air Station and each tended a squadron of submarines. So as not to settle down on coffee grounds, each tender would get underway for three days monthly to conduct drills, gunnery practice etc.

The LDO program was just being instituted and I took the exam for it. Just before being notified that I had been selected for Ensign, I was selected for promotion to Chief Warrant Officer. I had been a Warrant for six years and was not sure about "stepping down" to Ensign as opposed to being a CWO. My skipper and Exec (Karl Wheland and R.E.M. Ward) convinced me that I had a far greater future by accepting a commission as Ensign. In 1951 I was promoted to Ensign and received orders to the Naval Station, Tongue Point, Astoria, OR. I reported in and we were assigned very nice quarters on the base. My job (a LT billet) was Security and Ordnance Officer. The Station was originally commissioned as a Naval Air Station and bordered the Columbia River. It was now utilized to support the Columbia River Group, PacResFlt. While my job was challenging and I rattled a few cages while there, I felt it was a dead end. Most of the senior officers were on their twilight tours and it showed. I called the submarine detailer in BuPers and requested assignment to Diving School. I received my orders and after six months at Tongue Point, my family and I were on our way to Washington D.C. I completed a six-month course at the Deep Sea Diving in School in October 1952 and was ordered to USS Florikan ASR9 in San Diego. We again settled in Chula Vista and I had various jobs on Florikan. Operations, Communications, Navigator and Diving Officer. While serving in Florikan, I was promoted to LTJG. We did a good deal of recovery work during missile tests off the CA coast as well as the usual WestPac deployments.

Following my tour in Florikan, I received orders to USS Volador SS490 also home ported in San Diego. Again more WestPac deployment and interesting special ops. I was primarily on Volador to qualify (Officer) in submarines and spent a lot of time working on this in addition to my primary duties. I was promoted to LT while on Volador. After Volador I received orders to the Submarine Escape Training Tank, Pearl Harbor where I served as OinC. After a short stay in Navy Housing, Grace and I rented a new home in Pearl City, we were the only "round eyes" in the neighborhood and enjoyed living there.

Shortly after my arrival, we started conversion from training in the S.E.A. (Momsen Lung) to the Buoyant ascent method of submarine escape. The Tank at New London, CT was farther along in this new procedure so, in company with Master Diver Milo Holecek and Diver Bob Sheats I made a trip there to learn from their experiences; it was a worthwhile trip. In addition to submarine escape training, we provided diving service to the Submarine Base, conducted Diver 2nd Class and SCUBA training for PacFlt and provided treatment for many civilian SCUBA divers in need of recompression. ComSubPac headquarters was located across the street and we were called upon frequently, to provide tours and demonstrations for visiting dignitaries.

In 1958, after two years at the Tank, I received orders to USS Coucal ASR8 as Executive Officer where I served in this capacity for one year, then fleeted up to command. This worked out well for my family in

that Coucal was home ported in Pearl and a move was not required. During my tenure, Coucal provided services to submarines, diver and submarine rescue training and of course, a couple of WestPac deployments. All hands worked hard in this ship and it was awarded the coveted "E". During a deployment to WestPac, Coucal was assigned to work with the Japanese Maritime Self Defense Force and their new submarine "Oyashio." Basically, we were on detached duty and spent most of the deployment operating with the nips. We carried two nip officers on board, one a doctor and the other a line officer, the latter (LCDR Fuji) had been in their Navy during WWII and we got to know one another very well. The trial skipper of Oyashio (Capt. Hashimoto) was also an ex-naval officer in the IJN and had been the skipper of the I-58 when it sunk our cruiser "Indianapolis." These officers made it a priority that we see the Japan that "tourists" did not see and we went into several out of the way ports where we were given royal treatment. One excursion took us to Tokushima where our ball team was invited to play a game of softball. We were all shocked when we arrived at a large stadium and were introduced to our opponents. We were to play the high school national champion girls team and they beat our pants off. This was quite an affair, complete with TV coverage and local dignitaries.

In Pearl, Coucal was given the task of rigging and towing the decommissioned submarine "Tinosa" as a submerged target for aircraft ops. Given the nickname "Asonit" a manifold was installed topside so the hull could be submerged and suspended from four salvage pontoons. While towing her in rough weather south of Kauai, pad eyes welded to the hull with suspension chains attached, pulled free and Asonit made her last dive in some 2000 fathoms. I reported the loss to ComSubPac by dispatch and fearing the worst returned to Pearl. Upon arrival, I learned that the boss was mighty pleased with our loss, as he was not too enthused with being the custodian of a target hull.

Our son Jim arrived while I served in Coucal and rounded our family out.

In June 1960, I received orders to the Bureau of Naval Personnel in Washington, D.C. My new job would be in Functional Training where I administered Diver, Explosive Ordnance Disposal, Underwater Demolition and Underwater Swimmers training. Grace and I bought a new home in Alexandria, not far from Mount Vernon and we enjoyed living there. During my time in BuPers, President Kennedy directed the Navy to institute a "clandestine capability" and put a time deadline on establishment. I inherited this job

! and establishment of the SEAL (sea, air, land) Teams was initiated. Getting money reprogrammed and people for this was quite an undertaking. Most of the initial people had UDT backgrounds. Another project was authorization for a metal insignia to replace the embroidered diving helmet then authorized

for divers. The Supervisor of Salvage, Bill Searle, was energetically pushing the concept and I made the presentation to the Uniform Board. All went well and our divers finally had a pin type diving insignia.

After two years at BuPers, I received orders to command of USS Greenlet ASRI0 home ported at Pearl Harbor. We left our home in the hands of a property management company and headed west. The incoming OinC, Experimental Diving Unit/Deep Sea Diving School, Charlie Hedgpeth rented the home. Upon arrival in Pearl, many old friends including my Squadron Commander, to be, greeted us. He informed me that they were holding Greenlet up on getting underway so that I could ride her while she stood by a submarine making a deep dive. Great, I had not planned on this but was assured that my family would be well taken care of, and they were. Grace and I rented a home in Aiea Heights and enjoyed living there.

Greenlet like her sister ships left something to be desired in crew comforts etc. Soon after taking command, I started a "rehab" program. Arrangements were made with the Subase repair officer to allow Greenlet men to use the shops at night and they manufactured bunk lockers to replace all such items in Greenlet's berthing compartments. The spaces were completely refurbished and a recreation room/library was provided. Destroyers were being modernized in the shipyard and many goodies could be "appropriated" from them. Greenlet was fitted with the old six dog watertight doors and some of the topside doors leaked badly. Again, our shipfitters came to the rescue alld installed quick-acting doors from the destroyers. Our bridge was in need of modernization; we cannibalized part of a destroyer bridge structure and rebuilt ours. The bridge wings were extended out to the sides, thus giving the conning officer full visibility on either side. This alteration necessitated relocation of the port/starboard running lights; I was a little hesitant to do this but had already made so many unauthorized alterations, one more wouldn't hurt. Our final bridge structure now sported tinted glass windows forward, a radar repeater, rudder angle indicator etc. I know the crew was very proud of their "updated" ship.

On a deployment to WestPac, our first port of call was Sasebo, Japan where we went alongside the USS Ajax, a repair ship that carried a Flag Officer. This turned out to be a submarine officer (RADM Williams) who I knew from my days on Nereus. I made the usual call and the Admiral invited me to lunch, during which he mentioned that being familiar with ASRs, Greenlet appeared somewhat different. I told him that a good deal of work had been accomplished to improve the ship and invited him to look her over. I was surprised when he responded that he would inspect Greenlet right after lunch. He looked the ship over thoroughly and when he walked into my cabin, he exclaimed, "my God, you live better than I do!" The cabin was paneled with teakwood veneer, carpeted and nicely furnished. When we arrived on the bridge, Adm. Williams looked everything over very closely and said, "there has been a lot of recent

work done here, is all this authorized?" I could only answer truthfully, "Yes sir, the commanding officer authorized every bit of this work." He just nodded and I escorted him to the brow where he thanked me and left. That evening my exec and I a LT (George Riefler & Bob James) were ashore at the "O" club; Adm. Williams was also there and my officers decided to have a drink delivered to 'his table from the Greenlet. In response, the Adm. Sent a cocktail napkin to them inscribed as follows: "I have sent the following message to ComSubPac; I inspected your Greenlet today, what a magnificent little ship." I breathed a little easier when I learned of the message; J. W. Williams was not one to fool with.

Like Coucal, Greenlet operated out of Pearl providing services to submarines, conducting diver training, submarine rescue exercises and six-month deployments to WestPac. The submarine Rescue Chamber had a max working depth of 850' and a test depth of 1300'. Seldom was the chamber operated at depths greater than 300' and my concern was; what if a boat is down in say, 1000'? Prior to deployment to WestPac, I called on ComSubPac, Adm Clarey, who I had known for some time and held in high esteem; I explained my concerns and told him that I would like to lay a four point moor and operate the chamber in 1000' in Sagami Wan soon after our arrival in Japan. On arrival in Yokosuka, I explained the planned exercise to the Flotilla CDR and got the green light. In Greenlet, many calculations and preparations had been made, including testing the chamber to 1350'. We were assigned an area in Sagami Wan and proceeded there on a miserable rainy, January day. Laying the moor went well but the spuds were barely watching, while holding all the weight to the anchors. We centered in the moor and went to work lowering the false seat to the bottom. Initial soundings indicated we had 1000' of water but the actual seat was made at 942'. Lowering the false seat required close attention and was accomplished without incident. The chamber went over the side manned by CPO Davidson, GMI Smallwood and Ltjg James. A couple of "glitches" occurred that resulted in the issuance of alterations based on our recommendations.

Following the bell run, I sent a message to all concerned and naturally expected to hear something in return but only silence followed. CDR "Bo" Coppedge who had commanded USS Tang SS563 was on duty at the CNO and, noting the silence, originated a message from CNO congratulating the officers and men of Greenlet for their accomplishment; this was followed by several messages down the chain of command. Upon our return to port and checking in with the boss, he stated that he did not know whether to order a board of inquiry or pat me on the back for a job well done, His concern was that we had exceeded the working depth prescribed for the Rescue Chamber. I pointed out that I had told him personally of our planned operation and asked the question: "If one of our submarines was on the bottom in 1000', what would you order me to do?" Putting your boss on the spot is not the smart thing to do, but then, I never was a "rocket scientist!" On return to Pearl, ComSubPac backed me up on the operation

during my debriefing over the objections of his chief of staff (Capt. Walt Small) who had been "needling" throughout my presentation.

Greenlet was in WestPac when I received orders to the Experimental Diving Unit in Washington. D.C. My old friend, LCDR Lyn Clark, a survivor of Grenadier, relieved me in Naha, Okinawa and I was soon on my way back to Pearl. Grace had taken care of shipping our household goods and car and we enjoyed a short vacation at the Kahala Hilton with Jim and Ericka. Bill had previously returned to the mainland after graduating from high school. We had two cars, so Grace drove one and I drove the other across country. We did the usual house hunting and rented a place in Alexandria. I reported in to *NEDU* where my boss was Charlie Hedgepeth, also my tenant. About six months after reporting to *NEDU*, I was promoted to Commander and then received orders to relieve Charley Hedgepeth as OinC of *NEDU* and *DSDS* in early 1966. The Hedgepeth family left Washington and Grace, and I, with our children, moved back to our own house. *DSDS* was under BuPers, the OinC had additional duty to Buships as OinC of *NEDU* and BuMed had an active interest in both activities. This was a poor command structure and was resolved by CDR Gene Mitchell being ordered in as OinC, *NEDU*. *DSDS* was designated a Command and I was ordered to that post. The two activities continued to share the same building and some facilities. The pressure facilities in both facilities were old and tired and defects were apparent in the school facilities. Unable to get the BuPers people to recognize the severity of the situation, I finally sent a CASREP, effectively shutting the school down. This created havoc and the Chief Of BuPers directed me to meet him at the school for his personal inspection, the old boy was really mad over my message. I showed him pressure lines etc. that were ready to rupture due to years of deterioration, explained how we could have fatal casualties etc. He got the picture and cooled down considerably; we ended up getting a complete overhaul of our pressure facilities.

Late in 1968 Capt. Nicholson summoned me for an interview/briefing at his home on a Sunday morning. The briefing covered a classified project that involved divers/submarine operations being developed on the west coast by the Deep Submergence Systems Project and administered by the projects Technical Office at the Submarine Base, San Diego. I had orders to *DSSPTO* so we sold our home and Grace and children headed for San Diego where she purchased a new home in Del Mar and got the kids started in school. I remained in Washington until December when LCDR Billy Delanoy arrived to relieve me. Grace came back for the change of command and then, we drove out to California.

The SeaLab III project was being pursued by *DSSPfO*, the OinC, Capt. Walt Mazzone was well versed in all aspects thereof and I was not, thus it was decided that I would relieve when the project was completed.

In the meantime, I would acquaint myself with other DSSPTO activities in Long Beach and San Francisco.

The SeaLab III habitat was placed on the bottom in 600' off San Clemente Island, I had just arrived there by air and was promptly advised that an accident had occurred. Upon boarding the support vessel, I learned that two divers, CBOSN Bob Barth and Barry Cannon, a civilian participant, were in the PTC and that the habitat was flooding. Bob had brought Barry, who was unconscious, back to the PTC and communicated the problem to topside. A lot of discussion was going on among the senior officers, none of whom were line officers. They wanted to put additional divers down but CDR Jack Tomskey was reluctant to do this. Jack and I conferred on the subject and it was decided not to put more divers down but to get Bob and Barry to the surface as quickly as possible. I received dispatch orders to collect all evidence and put it in safe keeping and stand by to be a member of a Board of Investigation headed by Capt. Chase who was coming in from the east coast. The death of Barry Cannon, caused by an empty co2 canister in his diving gear, was essentially the basis for bringing the project to a halt. The underlying classified work could go forward with hardware and procedures thus far developed. Upon completion of the investigation, I relieved Capt. Mazzone. DSSPTO was absorbed by Commander Submarine Development Group One and the finest and most dedicated group of divers, the Navy had ever assembled, began dissolving.

By this time I was nearing retirement, our son Bill had just completed four years in the Navy on USS Haddock SSN621 and the two of us took on opening a new service station in Del Mar. Bill was the first to recognize that this was not for us and went off to diving school, then on to work for Taylor Diving. I kept the station for a short time then sold out. I then managed an automotive service/parts dealership for about ten years. During this period, Grace and I had a home built on Palomar Mountain in 1975 and retired to it in 1981.

SPAUR INTERVIEW

**UNDERSEA & HYPERBARIC MEDICAL SOCIETY**

**ORAL HISTORY OF THE MAJOR PARTICIPANTS  
IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS**

**INTERVIEW OF  
WILLIAM H. SPAUR**

Monday, October 27, 2003

## PROCEEDINGS

INTERVIEWER: When and where were you born?

DR. SPAUR: I was born in Wilkinsburg, which is a suburb of Pittsburgh, in 1934.

INTERVIEWER: Where did you go to school?

DR. SPAUR: From the first to the fifth grade, I was delightfully educated at an all-eight grades, one-room, one-teacher school out in the sticks near Zion, Illinois. Junior high school and high school were in Euclid, Ohio. I went to undergraduate school at Miami University of Ohio, and I got an M.D. from Ohio State.

INTERVIEWER: What influenced you to choose the Navy as a career?

DR. SPAUR: The draft was the influence. I've always liked the water. I lived on Lake Erie and always had small boats. I actually began diving there, probably in about 1952, when my father bought me a US Divers single stage Aqua Lung. He melted lead and made molds for a weight belt. I put on a sweat shirt, the tank, and the weight belt and waded into murky and cold Lake Erie. The Aqua Lung came with a six-page booklet that stated that the diver should always breath out on the way up and not dive deeper than 120 feet on the first dive.

When I was finished high school, the Korean War was going on and the military was drafting men out of college. Initially there was no college deferment. Ohio National Guard units were sent to the war. I spent the summer as a deck hand on an iron ore carrier on the Great Lakes, the second best job I ever had. So when I arrived at Miami University in the fall, I joined the Naval ROTC unit to protect myself from the draft.

I did three semesters in that chickenshit outfit. I quit the NROTC when college students were drafted only from the lower one-third of the class and because I was then a pre-medical

student. If I had stayed in and taken all the naval science courses, I wouldn't have been able to get all of my pre-medical requisites done.

When I finished undergraduate school, I would have been drafted into the Army, because my school deferment ended. So I went to medical school.

In 1960, four years later, as I approached graduation from Ohio State College of Medicine, I was again draft bait. There was a doctors' draft, everybody who got an M.D. was drafted, even some of the guys, I think, who had been in the Korean War as enlisted men. If one got an M.D., one had to serve two years in the military. I didn't want to go into the Army, and so in my senior year, I joined the Navy Senior Navy Medical Program to assure that when I went into the service, I could go into the Navy. That way I could do things around the water instead of being drafted into the Army. We even got ensign's pay the senior year of medical school. That was how I got into the Navy.

INTERVIEWER: After you finished your medical school, you did an internship, I guess, in a Navy hospital?

DR. SPAUR: I did. I did an internship at the Naval Hospital in Philadelphia. A friend of mine, Tom Balding, and I were the only graduating students asking for Navy internships. We decided we liked San Diego, but if they gave us our second choice, we would go to Oakland. We bought ragtop sports cars for our car trip out west. I bought a white MGA, and he bought a black Triumph. We prepared to cross the United States on Route 66 in our ragtop sports cars. We both got orders to Philadelphia.

INTERVIEWER: When you finished your internship, I imagine you were ready for some kind of Navy assignment. I guess that you also did a residency in internal medicine.

DR. SPAUR: Yes, I did. When I finished my internship at the Philadelphia Naval Hospital, all doctors had to go to sea or serve with the Marines after their internships. I saw the opportunity to go to diving school and submarine school. Back then, when you were recruited to submarine school, the detailers only talked about billets as submarine squadron medical officers and diving billets.

When I was in Philadelphia, I belonged to the Philadelphia Sea Horses. I used to dive every other weekend. I was doing a lot of diving. I was pleased and most excited to go to diving school and submarine school to follow.

One day when we were in diving school, the detailer came in and said, "Well, 27 of the 30 of you are going to SSBNs." We all looked at each others' puzzled faces. One of the guys raised his hand and plaintively said, "Sir, what's an SSBN?" We didn't know. Nearly all of us went to submarine billets.

INTERVIEWER: Didn't you go to New London first?

DR. SPAUR: Yes, after Deep Sea Diving and Salvage School, we went to New London for submarine school, regular officers' submarine school. Ten or eleven of us went to nuclear power school following submarine school. I didn't wish to go to nuclear power school, but I did get interviewed by Admiral Rickover, so I have my story to tell.

I had the opportunity when I finished submarine school to choose temporary duty in Key West. I was there for three months as the Squadron Medical Officer for Submarine Squadron 12. I relieved Warner Dewey and was then relieved by Julio Rivera. Warner had just published an article about decompression sickness in *The New England Journal of Medicine*, which was really nice. Walt Bergman was the executive officer of the ASR *Penguin*. I dived two or three days a

week off the *Penguin*, usually in a four-point moor, and every weekend I went diving on the reefs with the chief corpsmen. I had a wonderful time in Key West.

INTERVIEWER: Did you interact with the Underwater Swimmer School?

DR. SPAUR: Charlie Aquadro had just left the Underwater Swimmer School and Micky Hoffer had arrived. Micky Hoffer was a wonderful competitive swimmer from our submarine school class. He was from New York, not yet tamed, and a source of great fun for me in submarine school. The medical officers took the same classes as regular submarine officers. For instance, we had 18 hours of lecture on lead batteries. We would be grinding through these lectures and Micky would raise his hand in the back of the room. A lieutenant commander or lieutenant, being very serious about coming to the submarine school and lecturing, would say, "Yes, doctor? You have a question?" Micky would respond, "Why the fuck do we have to learn this?"

INTERVIEWER: That sounds like him.

DR. SPAUR: The diving school and the submarine school really didn't know how to handle medical officers. The schools tried to treat them as if the medical officers respected Navy authority, but the medical officers just did not understand. The drafted medical officers that came into the Navy at that time were adults. They were 26 or 28 or more years old. Some had had residency training. Anyway, they were adults and had never been in the service and they just didn't respond to being yelled at. They just looked puzzled.

INTERVIEWER: I was a commander at dive school. I used to swab down everything. I remember swabbing down and one of the enlisted guys came and said, "Commander, you're not supposed to swab." I said, "I'm going to behave just like everybody else and swab down."

DR. SPAUR: Micky Hoffer had a wonderful story. We were in New London in the wintertime, but we didn't wear the heavy wool coats. We just ran between classes in our dress blues. Micky

Hoffer was running from one class to another with his gray gloves on. Remember, at that time we only *carried* the gray gloves. Unless you had on a great coat or a raincoat, you didn't actually put them on. Micky was running from one class to another and this voice behind him said, "Lieutenant, Lieutenant, stop." He turned around and there was this Captain behind him. He just turned around and started going again. The Captain shouted, "You, Lieutenant, stop!" Micky turned around and said, "Yes, sir." The Captain said, "Come back here." Micky went back. The Captain said, "You have your gloves on." Micky said yes. The Captain asked, "Why do you have your gloves on?" Micky stuck up his fingers and wiggled them. Then, he said slowly with that small, condescending, doctor's voice used for disturbed patients, "Because it's cold, sir?" The Captain was getting redder and redder and redder in the face. That was Micky.

INTERVIEWER: He was like Walt Mazonne when he was at New London. It was a hot day and Walt was driving around in his convertible with no cover on. He got reported.

Finishing up at sub school, you had to write a thesis on something. Did you pick an interesting topic to write about? What did you do?

DR. SPAUR: I did not. We were supposed to take a big exam. It was about an inch thick. We also were supposed to write a paper about something. I did neither. I never, ever got dolphins, which saved me from a lot of bad jobs.

INTERVIEWER: Oh, sure. At that time, beginning your diving career, was there anybody who was an influence on you? Perhaps someone said, "Diving was a great thing for me and medicine."

DR. SPAUR: I think what I remember most was being at Key West, operating off of the *Penguin*. They just treated me like I was really something special. Whenever I came aboard, they said, "Squadron Medical Officer arriving." Walt Bergman would come and take me to the

wardroom, and we would have coffee and cigars. The *Penguin* would put to sea and place four-point moors. Operations were always exciting to me. Captain Ralph Fawcett was the SUBLANT Medical Officer. I liked him a lot and had great respect for him. It was all was fun.

INTERVIEWER: In diver training, did you see any part that was especially difficult, or even down at Key West?

DR. SPAUR: The Deep Sea Diving and Salvage School training was extremely well presented. I can't remember who the lecturers were. But diving school was a very good course. I enjoyed it a lot. We learned on the Mark V, of course.

When I went through diving school, SCUBA was just being introduced. Many of the senior diving enlisted men really couldn't swim. On our runs, we would, at the prodding of the chiefs, sing, "Hard hat, si, SCUBA, no! Hard hat, si, SCUBA, no!" as we ran around. The senior divers were not trained to dive by themselves with SCUBA. They were accustomed to running those big underwater machines, the Mark V.

INTERVIEWER: When I went through dive school, which was about 1963 or 1964, that attitude still prevailed. I liked Mark V diving.

DR. SPAUR: Oh, it was great fun. We trained in the Anacostia River, which I knew would be black and have zero visibility. But I forgot that it was going to be black inside the helmet too. There was three or four feet of soft mud on the bottom and it did not support, just squished and mired. It was fun.

INTERVIEWER: Do you think your diving career has had any effect on your later life?

DR. SPAUR: Oh, sure. I've always liked diving and I like marine biology. I like boating and the whole water thing. I continue to dive. I dive here on the canal on my neighbors' boats when they

get something stuck in their props or need zinc changes. I search for glasses and tools dropped. I don't do any recreational diving anymore, but I certainly did for most of my life.

INTERVIEWER: Do you keep up with diving literature or any diving magazines or journals?

DR. SPAUR: In the commercial field, I get the Association of Diving Contractors' *Underwater*. I read it carefully because there are many Navy men and civilians that I knew who are still in the diving business. Fred Ackley, the current president of the Association of Diving Contractors, was at EDU when I was there. The past president, Jack Reedy, was our EDU Chief hospital corpsman. He organized and ran all the medical department dives for me.

INTERVIEWER: In your diving career, what were the most memorable experiences that you can recall right now?

DR. SPAUR: I think the most fun diving was in the Florida Keys. I had gone to the Keys twice to dive while I was in medical school. Then I dived with Submarine Squadron Twelve, then returned to do equipment evaluations while at EDU. It was spectacular. Back then, the Keys were wildly full of fish and the reefs were healthy. There was a grouper in every hole, you know. Divers were so unusual when I first went there that boats would come by and people aboard would say, "Look, look, there are divers. There are divers. We want to go see the divers."

INTERVIEWER: There was no one incident or experience in diving that stands out in your mind?

DR. SPAUR: Well, the greatest experience of my life was being the Senior Medical Officer of the Experimental Diving Unit. I had that job for ten years. That was a big hunk of my 30 years in the Navy, especially since about six of the other years were in residency, fellowship or other training programs. That was the best job I ever had. I just loved it. The second best job was being a deck hand on an iron ore carrier on the Great Lakes. I only did that four months.

INTERVIEWER: At that time, there was an emphasis on research, mostly harder research. What did you experiment on? Did you get the kind of support you needed from the Navy to do the research?

DR. SPAUR: Oh, absolutely. The Experimental Diving Unit is an engineering command, part of the Naval Sea Systems Command. We were problem solvers, tasked to improve equipment and diving procedures and quite adequately budgeted. We were a small group, but I thought we worked wonderfully well. We had very distinct problems to solve, like how could the breathing resistance on this underwater breathing apparatus be improved? What oxygen partial pressure should be provided? How deep and how long to limit the dive? How much cold could the divers tolerate? How could the divers be kept warm? What decompression procedures would be safe? It was, as Chris Lambertsen called it, 'limit physiology'. We all were married to the underwater breathing apparatus and the diving chambers. The medical officers and psychologists were married to the engineers and divers. The great challenge was to develop instrumentation to measure the physiology of the divers and the function of equipment under water, then to make the humans and life support apparatus work well together. Then we wrote it in the Navy Diving Manual, the bible of diving.

INTERVIEWER: That leads me to my next question. How much of what you did there was investigator-originated, or how much came down to you from the Bureau and said, "We need an answer to this?"

DR. SPAUR: Almost nothing came from the Bureau of Medicine and Surgery. The Bureau tasked the Naval Medical Research Institute. Our task was to support operational diving and the Supervisor of Diving and Salvage at the Naval Sea Systems Command. There was always equipment that needed improvement or replacement. There were diving procedures,

decompression tables and treatment procedures that needed revision or replacement. Major projects such as the generation of new decompression tables can only be attempted every twenty years or so because the dive series is so expensive, requires great numbers of dive subjects and might require a year or more of work. Even then, such an attempt might fail.

On all underwater breathing apparatus, we tried to perform physiologic testing with divers performing maximum work underwater, in cold water, at the maximum operational depth.

Even a simple study, for example finding the correct over-bottom pressure to supply the second stage regulator of a surface-supplied underwater breathing apparatus, might require months of engineering breathing machine studies and numerous dives with instrumented subjects. Then the results would be applied to equipment selection, diving procedures, depth limits, and other related concerns.

When EDU finished these experiments, we would then write it into the Navy Diving Manual. The work that we did had to stand for decades. Large experiments couldn't be repeated for a long time. I rewrote great portions of the Navy Diving Manual during the ten years that I was there. We made tremendous advances, and I felt like everything we did was building a structure that had to last. Our recommendations had to last at least until somebody had another three million dollars and thirty dive subjects and a year to do the work again.

INTERVIEWER: Well, the diving manual, the U.S. Navy Diving Manual, is certainly par excellence around the world for everybody, not just in the U.S.

DR. SPAUR: Well, the Navy Experimental Diving Unit is the only organization that had the enormous funds and the huge number of subjects to do adequate experimentation.

INTERVIEWER: Were there any life-threatening or dangerous experiences that you can recall while you were diving?

DR. SPAUR: No. I'm pretty phlegmatic. If I was in some dangerous position, I probably fell asleep or daydreamed. I think that if my life had been threatened, I was too dull-witted to understand that I was in trouble. We did a lot of the exercise experiments underwater in which the end point was terrifying, choking dyspnea. That was awful to experience. You always knew that if you could climb out, it was going to end in awhile. I don't remember ever worrying too much about whether I was going to lose my life.

INTERVIEWER: Which physicians or others served as role models, but you already answered that, in essence.

DR. SPAUR: Well, I should say that while I was at the Experimental Diving Unit, I had a constant rotation of absolute geniuses, physicians and psychologists who were far, far smarter than I.

INTERVIEWER: Were they two-year assignments?

DR. SPAUR: Some officers were there for only two years, then transferred to other diving assignments. When I first got to EDU, Ed Flynn was there. He was certainly the best physiologist in diving medicine in the Navy at the time. John Alexander, a fellow pulmonologist, continued as a civilian to have diving interests. Jim Summit, whom I replaced, was a great administrator and writer. Brandon Wright came from the University of Pennsylvania program. Ed Thalmann started at EDU after his civilian internship. So, Ed has been studying diving since 1972. Then came Bill Braithewaite, who was an electronics genius. He did all our chamber thru-hull instrumentation and electrical balance of the ground currents. He wired the communications and the helium unscramblers. Where do you find physicians who know how to do chamber electrical grounding and troubleshoot the electronics of helium unscramblers? Only at the Experimental Diving Unit. Tom Berghage, Rob Carter and David Styer championed human

engineering of diving equipment. Claude Piantadosi was at EDU before moving to Duke. Larry Raymond came from NMRI to be a diver on the 1600 foot dive and subsequently penned the most beautiful diving physiology papers.

INTERVIEWER: I'm going to make a broad jump in thought. Is there a specialized area or areas in Navy diving that you think needs more emphasis on research?

DR. SPAUR: I think that I've been out of the diving research business too long to answer that question. It's been 23 years since I left the Experimental Diving Unit

INTERVIEWER: What about submarine rescue? Do you think that there is a role for divers, or do you think that is best left to DSRVs?

DR. SPAUR: I don't think I'm very knowledgeable about submarine rescue. When I was on the USS *Ethan Allen*, the SSBN-608, I had two divers and myself. I thought that we served a function in shallow water had a cable gotten around the propeller or some similar situation. We could have gone out, either with the submarine surfaced and gone over the side or possibly have gone out underwater had we been absolutely stopped. I don't know if that has ever happened. Certainly that could happen, with all of the nets and trawls that are around in the ocean.

I worked all the years at the Experimental Diving Unit for the 'projects,' as they were called, which were highly secure operations at the time but have now been fairly well published. Much of the work I did was sponsored by the projects, which was diving out of submarines.

INTERVIEWER: You mentioned that you were at the EDU for ten years?

DR. SPAUR: Yes.

INTERVIEWER: That's an unusual length of time for a Navy officer to be assigned to one billet.

DR. SPAUR: Yes, but medical officers frequently spend nearly their entire careers at one hospital. They just move up from interns to residents to staff.

INTERVIEWER: But EDU is not a medical facility.

DR. SPAUR: Ed Thalmann was there maybe eight years or so, but I don't know. Marie was there for many years.

INTERVIEWER: I think it's smart of the Navy, when they find somebody who is doing a good job at a facility, to leave them there.

DR. SPAUR: Well, I think that the detailers didn't know what to do with me.

INTERVIEWER: In regard to diving research, what brought you the most satisfaction in the work that you did?

DR. SPAUR: I worked on a number of things that I made headway on and some that I didn't. When I first got there in 1970, it was not too long after Bob Bornmann and Bob Workman had published their papers on using the sixty-foot treatment tables. I was determined to change the routine of treatment table selection so that treatment activities would use the sixty-foot oxygen tables. The Diving Manual in use in 1970 invited the selection of the air tables just as much as the 60-foot oxygen tables.

I rewrote all that, and Tom Berghage made choice diagrams similar to logic or computer programming. We introduced those into the Manual. I tried all the time to get treatment really confined to sixty feet on oxygen. I was never successful in that because the submarine escape people always wanted 165 feet for the towers. That 165-foot treatment always remained. No matter what I wrote or what we taught, if you went over to diving school, they were still talking about going to 165 feet. That continued. In 1976, we began work on a saturation treatment method at 60 feet. My motto was that every diver who was going to die in the treatment chamber, should die at 60 feet not at 165 feet. At 165 feet attendants were in trouble, it was

difficult to breathe, and nobody knew what they were doing. Ed Thalmann completed those studies to make Treatment Table 7.

INTERVIEWER: Sure, it's accepted now.

DR. SPAUR: There was another project that I started working on soon after I got there. We had gone with John Rollins to Farmborough, England, and looked at aviation and diving equipment. Because the Royal Navy was small and had a small research program, they had to marry industry and Navy research. They couldn't afford to have separate programs.

While I was at the EDU, I always tried to make it so that the engineers and the medical officers were working on the same things in tandem. I introduced the medical experimental protocols and every department signed off on them. There was no engineering project that the medical department and the engineering departments, the SEALs, the EODs, the commanding officer and the rest of the people didn't sign off on. With every single experiment we did after that, whether it was in engineering, medicine, physiology, equipment testing or decompression tables, everybody was responsible for it. There were about six of us, I guess, as department heads. I thought that worked very well because it made the engineers responsible for the equipment that we were using. We were responsible so that the engineers didn't hurt anybody. We all took responsibility. Using that organization, I was able to push away people who said, "You should have a human research committee." Human Use Committees are an outside group of people that really don't have any responsibility, trying to approve what they don't understand and have no responsibility for. I said, "No, we have our group. Everybody is responsible." I thought it worked very well.

INTERVIEWER: Speaking of equipment, I understood that the Navy EDU had responsibility for looking at diving equipment after a major diving accident. Did you assess the safety of equipment or equipment failure? Did the EDU have that responsibility?

DR. SPAUR: I think so, though I cannot recall being involved in it. I think that the engineers did that. We tested a lot of equipment and found many commercial helmets lacking in their ability to ventilate. Some SCUBA regulators had higher resistance than the better SCUBA regulators. Some of our own Navy underwater breathing apparatus, like the Jack Brown mask, was by any standards, terrible. It was still in use. Even when I left after ten years, I think it still may have been.

INTERVIEWER: Did you have any regrets or disappointments in your career in undersea activities, as you look back on it?

DR. SPAUR: Well, yes, I regret that I couldn't stay in it after I finished at the Experimental Diving Unit. I had to go back into hospitals and see patients for the rest of my eight years in the Navy. I would've loved to have some diving responsibility.

INTERVIEWER: I'm sure. It didn't seem very smart for the Navy to do that. The first priority for the Navy physicians is hospital and patient care. Operational people are second.

DR. SPAUR: Seeing patients in the hospital never rewarded me very much. As a pulmonologist in internal medicine, one came to the office in the morning, opened the door and there was a waiting room full of patients. I would work all day caring for them. The next day, I would open the clinic door and find an equal number to take care of. There was no getting ahead. I felt good about helping them out, but anybody could have done that. In clinical practice, the whole world is sick people. It used to be depressing. I felt sorry twice over for sick people. First, I felt bad because they were sick and second, because I was their doctor.

INTERVIEWER: I am sure that you gave very good care. Did you do that at Bethesda or Portsmouth or somewhere else?

DR. SPAUR: After I did my temporary three-month duty in Key West diving with the *Penguin*, I went to the SSBN *Ethan Allen*, 608, out of New London. The *Ethan Allen* made patrols out of Holyloch, Scotland. I made three patrols. At the end of the second patrol, I had on paper actually finished my obligation to the Navy. I had signed up for submarine school and was required to stay two years longer after my completion of submarine school. But BuPers extended that.

I thought that I'd lost about ten points of my IQ each patrol. I didn't have all that much to start with. I was never really that smart. I still owed time, so I was thinking, "How am I going to get out of this?" The only way to get out of it was to take a Navy residency. I applied for a Navy residency and went to Bethesda, the National Naval Medical Center, for internal medicine. The internal medicine residency was from 1964 to 1967.

In 1967, the hospital at Da Nang was really hot. All doctors who finished their residencies were off to Da Nang, where the rounds aimed over the hospital at the airfield were falling short. I didn't agree with the Vietnam War, and I didn't want to go to Vietnam. I thought I might act badly in combat in a war that I did not want.

INTERVIEWER: I agree.

DR. SPAUR: I felt the whole war was horrible, just horrible.

INTERVIEWER: The surprise I had was that Bob Workman was my boss, and Bob was very much against the war. I was, too.

DR. SPAUR: Well, it was sort of unspoken at the Naval Hospital. You just didn't talk about it most of the time. It was just awful. It went on and on. While I was working at Bethesda and St. Albans, we had hospital corpsmen coming out of corps school to perform their first three or six

months at the hospital and then go off to Vietnam. In weeks, some came back legless. They were people I knew, and that was just heartbreaking. Anyway, when I finished my internal medicine residency, instead of being available for combat, I took a pulmonary fellowship in chest disease at St. Albans Naval Hospital and then stayed on the staff for two years.

I applied through Captain Ben Hastings for a diving billet. I had always been asking for a diving billet. While I was on the submarines, I asked for a diving billet but couldn't get one. The diving detailer at that time was Captain Shulte. I went to see him and I said, "Can I have a diving billet?" and he rocked back in his chair, laughing, and said, "Ha, ha, ha, ha, ha! Of course you can have a diving billet, Bill. Ha, ha, ha, ha!" Then, I went back to New London and got a letter that read, no. He was such a strange man.

INTERVIEWER: I think he went to Ohio State University and was there for a couple of years and died.

DR. SPAUR: Yes, he did. He had a chamber at Ohio State for occupational and industrial medicine. I never saw him there. But that is my alma mater.

INTERVIEWER: Let me take another tack here. In diving research over the years, what would you single out as the most important contributing factor to successful diving operations?

DR. SPAUR: I think the most important, longest-standing project that I did single handedly, at least initially, was the unlimited duration saturation excursion tables for helium/oxygen saturation diving. Bob Bornmann had calculated the saturation excursion tables using the M-Value mathematical formula for SeaLab III. These were tested as calculated at EDU in a large series of dives that was free of excursion related decompression sickness. But nobody knew the limits. The tables had been calculated using M-values, which were standard at that time for calculating non-saturation diving. Before I started on the unlimited duration saturation excursion

diving tables, I looked at all the dives recorded at EDU, England and elsewhere. There were many, many cases in which the excursions upward were way beyond the limits of the SeaLab tables that had been calculated using M-values. For instance, with the tables as they existed, the diver was prohibited from ascending more than 33 feet above the saturation depth. I was doing a dive at the Royal Navy Experimental Diving Unit, RNPL. It was late at night. The divers were at 1,000 feet. We had been there for three or four days. The chief on the watch said in his best British accent, "Permission to make up, sir." I asked, "Make up what?" The chamber had lost depth. The Diving Officer said, "No. Let's see if we can find the leak and the reason we are going up." We had gone up 80 feet, and they thought nothing of it, whereas in the U.S. Navy, there was the rule that if you were at saturation depth, you couldn't go up 33 feet because something terrible would happen to you. Many other dives recorded had great excursions upward before beginning a slower decompression.

EDU had attempted to develop four-hour bottom time decompression tables for 450 and 650 feet depth soon after I arrived. The objective was to descend for four hours of working bottom time, then come up a distance with only a few stops to start a saturation decompression. The calculations were done by Ken Bondy or Dick Buckles at NMRI using M-values. We had some very bad decompression sickness and abandoned the attempt, but there was evidence that some kind of similar approach was possible. I wrote protocols to test the limits, not of how deep to make an excursion from saturation depth, but if the diver went deeper, how long could he stay there and return to the saturation depth. The theory was that if one saturated at some depth, there had to be a distance that one could ascend and then start saturation decompression without getting decompression sickness. That was essentially all it was. I started there. But most of my comrades in diving research had spent so much time using M-values and learning how to

calculate them, which was extremely tedious before computers, that they believed that the equations represented tissues of the human body. It was an odd phenomena. By the time somebody finished learning how to do M-values, they believed that what they were doing was physiology, instead of some math. Myself, being ignorant of mathematics, and knowing that patients did not respond according to equations, I did not share their love of M-values.

Bob Bornmann even took it upon himself to come from his command, and I don't remember where he was at the time, but it didn't have anything to do with Naval Sea Systems Command, and talk to Captain Huntley Boyd, my boss. He told Huntley Boyd that I was taking the wrong approach to testing these tables and that what we should be doing was extending his tables.

Ed Flynn was also wrapped up in M-values and wanted to do some excursions which would aid in adjusting M-values. I disregarded all that. We would not use any theoretical calculations but just start and see what could be done. It worked. We were very successful in constructing upward excursions from 1,000 feet and shallower..

We published the studies in the *Undersea Medical Society Journal* and the Navy Diving Manual. Now, the limits have been adjusted by further experience and studies. The Unlimited Duration Tables for Saturation Diving absolutely changed the way saturation diving was done everywhere.

INTERVIEWER: Recently, I spent some time with Bryan Barrett and his interview brings to mind the question about interaction with the British. Did you feel that it was beneficial to the U.S. Navy to have that kind of interaction?

DR. SPAUR: Oh, yes. In fact, when I started the unlimited duration excursion tables, Peter Barnard was doing 33-foot jump saturation decompressions which certainly pointed the way for

us. I thought it was absolutely essential that we be well acquainted with everybody else and have an exchange with the Royal Navy. Julian Malec and I still exchange letters. You see Bryan Barrett often. I always went to the meetings in England, and they came to us. I thought it was useful, as well as the work that the Swedish and French were doing at the time. The scientific community, if it is open, is much better. One of the moves that I fear now is the attitude that the US should limit publication. We will suffer.

When I first came to the Experimental Diving Unit, there were three or four different kinds of reports, some of which, like a commercial helmet evaluation, had limited distribution. I stopped that. Since this is taxpayer money, everything we do will be in an Experimental Diving Unit report. Everything we do will have an unlimited distribution, and be open to the public. Everything we do will be set as closely to a scientific paper as we can make it and reviewed and signed off on by everybody. But when I visited the Experimental Diving Unit about three years ago, I noticed they had an enormous vault in the library. I wonder what has happened since I left.

INTERVIEWER: The Royal Navy is no longer assigning exchange officers. Over the years, physicians who were assigned to NMRI were really outstanding researchers. I think the U.S. Navy benefited.

INTERVIEWER: Do you see a future for diving research in the U.S. Navy? Do you feel that we've reached, not necessarily a dead-end, but like the oxygen association curve, there is only so much more left to do.

DR. SPAUR: I worked a long time with underwater breathing apparatus for combat swimmers. We were developing ways to use the oxygen-add rebreathers, reducing the breathing resistance, extending the carbon dioxide scrubbing capability, and doing simple things like human factors. For instance, the oxygen valve button and the diluent valve buttons on a rig were the same on the

initial specifications. I think Rob Carter was our psychologist at the time. He worked out that one should feel pointed to the gloved thumb, and the other one should feel like a hole in a circle.

How do you figure out mixes, diving procedures, decompression tables and breathing apparatus for combat swimmers operating for long periods in the water at variable depths. It is terribly complicated. Protection against cold is difficult. Those operations will always be problematic.

INTERVIEWER: Do you think the Navy has made a mistake in limiting diving research and even diving to shallower diving? They are not into deep saturation diving. Do you think that is a mistake?

DR. SPAUR: I don't know. Actually, I don't know what the mission is at the present time, so it's hard for me to talk about that. I don't know what our operational platforms and capabilities are now, but the U.S. Navy is the biggest experimental group. No one else can match the Experimental Diving Unit facilities, the number of divers, and the brain power of the diving medical officers and engineers. I think the Navy should always be looking at all aspects of underwater work, whether it is deep or shallow, helium or nitrogen. The equipment always will be advancing as technology advances. When I came to EDU, there were no oxygen partial pressure sensors. Arterial blood-gas studies were still being introduced into medical practice.

INTERVIEWER: You are actually one of the first people with whom I've talked who has been involved in diving research and is still very positive about what the Navy can do in the future and it's nice to hear that. Some of the people with whom I've spoken feel it's kind of a dead-end now.

DR. SPAUR: Oh, wow.

INTERVIEWER: They think there's no real future.

DR. SPAUR: I don't understand that, because supporting combat swimmers, and the procedures for locking out of submarines, and traveling underwater must be used more now than ever before. Deep saturation-excursion diving out of submarines sitting on the bottom, is an incredible capability that opens up the whole sea floor, at least down to 1200 feet or so. The Navy and commercial interests must have the capability to put divers out at every depth possible.

I don't know of any advances in the capability to put divers deeper than 1200 to 1500 feet and have them able to work. I was a subject on a 1400-foot dive. It was like having the flu for the weeks that we were deep. When I finished that 1400-foot dive, I had these deep lines across my fingernails that people develop after they have been terribly ill. They gradually grow out over time.

Several years later, EDU made an 1800-foot dive. The divers did not feel well nor think well. Everybody has tremendous weight loss on deep dives. Lots of good physiology to study there.

INTERVIEWER: You noticed that in your own fingernails?

DR. SPAUR: Oh, yes. It took weeks and weeks to recover from that.

INTERVIEWER: Once on the surface, you still felt as if you were recovering from some major illness.

DR. SPAUR: Oh, yes, I felt that way for weeks and weeks. I had never built models. I never had the patience to sit down and build model airplanes or anything like that. I could never sit still that long. After the 1400-foot dive, I just wanted to sit, so I went out and bought a model tugboat to build. I was back at EDU after resting a week and I met Ike Euteneier. Ike asked, "Do you know what I did, Dr. Spaur? I just went out and bought a model airplane. I'm building a model

airplane. It's the first one I've ever built in my life." I said, "Ike, I'm building a model boat. It's the first one I've ever built in my life."

I just didn't want to do anything. I weighed 155 pounds before the dive. I was down to 145 pounds after it. The other divers were similar. On that dive, I think we were thinking fairly well, but on the 1800-foot dive, which was the last deep dive we did at the Experimental Diving Unit when I was there, the divers were not thinking well at all.

We had a SEAL chief by the name of Boxy Holmes who was in the chamber. We had very good helium unscramblers. We had very good communication. Boxy had the gas sampling line that sampled a mask to come out to the mass spectrometer. He had a female end in his right hand and the male end in his left hand. We said, "Boxy, fasten those two lines together so we can begin to get samples." He'd look at one. Then, he'd look at the other, and we'd say, "Boxy, put the female end in your right hand and the male end in your left hand together. Put those two together." He'd look at one, and he'd look at the other, but he wouldn't make the connection.

I have re-read Larry Raymond's physiology publications. Larry came from NMRI to be a subject on a 1600-foot dive that we did at Taylor Diving and Salvage in New Orleans. What beautiful papers. I was afraid we had dropped him and drowned him too often, but he was still brilliant after the dive.

INTERVIEWER: You don't really think that using hydrogen as part of the mix was any answer to that?

DR. SPAUR: I don't know. I am aware of those attempts, but I do not know if the procedures were practical for commercial diving.

INTERVIEWER: DeLauze closed down their research facility.

DR. SPAUR: Robert Stenuit's book about his and Henri DeLeauze's treasure diving is up there on my shelf. He had funny stories to tell about that.

INTERVIEWER: He has a very interesting home. Have you been to his home?

DR. SPAUR: Yes, it's the house with the big windows overlooking the harbor in Marseilles.

INTERVIEWER: It also has the big fish tank that you see when you walk in.

DR. SPAUR: It was a nice visit.

INTERVIEWER: Is there anything else you want to add?

DR. SPAUR: I worked on trying to use the sixty-foot tables. I worked on getting the engineer's side of the house, the medical officers and the psychologists to work together.

In fact, when I reported to the Experimental Diving Unit in 1970, Steve Reimers, who is just a wonderful hyperbaric engineer, was there. He was finishing his breathing machine. That was the first really good breathing machine. Steve started the studies of all the underwater breathing apparatus at depths exactly where they would be used. We had noise and sound measurements in those machines so that we knew what the helmet noise levels were. Noise was a big problem with the Mark V and the initial Mark XII.

We set standards for testing. I, along with my medical officers, set a standard that every apparatus should be tested as though the diver could do severe exercise at three liters of oxygen consumption. For long-term canister breakthroughs, we should use a standard of 1.5 liters of carbon dioxide production a minute. For every breathing machine study, helmet study and regulator study and everything that the engineering side of the house did, one medical officer was assigned to keep track of that study and be knowledgeable so that we could follow what physiology standards we should test to. Then, we would test it with human divers in the water using the same kinds of instrumentation. It really worked out well.

INTERVIEWER: Carl Edmonds and his group in Australia have a breathing machine that they used to use to test a lot of their equipment. They worked on it for a long period of time. Was John Harter at EDU during any of the time you were there?

DR. SPAUR: Yes.

INTERVIEWER: Did you ever dive with him?

DR. SPAUR: Yes, John Harter was at the Experimental Diving Unit, but not long after I arrived..

INTERVIEWER: He went down to Taylor.

DR. SPAUR: He had a good wooden sailboat. It might have been the *Mason* or something, but I can't remember what the name was.

INTERVIEWER: It was the *Nickerson*.

DR. SPAUR: Yes. That's right.

INTERVIEWER: It's kind of sad that the Navy sent the guy off to skipper a Navy tug, when he had this great capability as a diving engineering officer. Eventually, he left the Navy.

DR. SPAUR: I cannot remember all the things that John did. We had just brilliant engineers, Navy and civilian.

INTERVIEWER: Well, it seems to me you had a fruitful career in the Navy to look back on and feel very accomplished about.

DR. SPAUR: Yes. Of my thirty years in the Navy, I had about 15 years that had some diving responsibilities and ten years of doing underwater diving research at the Experimental Diving Unit, which was fantastic.

INTERVIEWER: You were lucky that you were never saddled with administrative assignments.

DR. SPAUR: Well, I was administratively incompetent, had no knack for it. When I was at EDU, someone said, "You know, you should become Atlantic Fleet Submarine Medical Officer next." I responded, "Look here. Look here at this shirt. I don't have dolphins. I can't do that job."

When I was at the Portsmouth Naval Hospital we were deployed with the M-MART teams in preparation for Desert Storm. I went to the Mediterranean Sea and Kenya and Diego Garcia with marines. I invaded a quiet little town in Norway with amphibious assault craft and tracked vehicles, tearing up their lovely seaside parks. Every physician had an operational assignment. As we got closer and closer to Desert Storm, we spent more than half of our time practicing for it. At that time, though, we didn't know who the enemy was, or where we were going to invade. We were going to invade somebody, though. The medical corps admiral in charge of Atlantic combat medical support called me in and said, "Would you like to be the head of these combat medical teams in the Atlantic Fleet? You get along with the line officers, don't you?" I said, "Oh, no sir! I get along with the engineers. I don't get along with the line officers."

INTERVIEWER: Did he believe you?

DR. SPAUR: Oh, yes. I didn't have to do that assignment. I was hard to place. In the Navy, when the music stopped, I always sat down between the chairs. That was the way I kept a good job, really. When I was at St. Albans Naval Hospital as a pulmonary fellow, I observed the head of internal medicine. I thought, "I'm not smart enough to do that job. I'm not a good enough internist to be the head of an internal medicine department. How do I keep out of the job if I'm not smart enough?" When I failed the oral part of Internal Medicine Boards, part two, I never took them again. That assured that I would never be a department head.

Then, to keep out of submarines, I never did the written examination to qualify for dolphins.

And so, that is a review of the spotty career of a man sitting between the chairs.

INTERVIEWER: Well, if you have nothing else, I guess we can close it up.

DR. SPAUR: That's good.

(Whereupon, the INTERVIEW was concluded.)

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF ROBERT “BOB” BARTH

Kensington, Maryland

April 2003

## P R O C E E D I N G S

MR. BARTH: My name is Bob Barth. I'm a retired chief warrant boson, but I've been out of the Navy for a good number of years, thirty to be exact.

INTERVIEWER: How far away from the sea were you born?

MR. BARTH: I was born a mile and a half away.

INTERVIEWER: Where was that?

MR. BARTH: I was born in the Philippine Islands, in the capital, Manila. My father was a U.S. Army officer stationed there. He was one of the early Philippine scouts stationed in the Philippines. He had been there ten or twelve years before I was born, and I lived there until the Pearl Harbor days. I got out just before Pearl Harbor was attacked. I came back to the States. My parents, my mother and my stepfather, by that time, had stayed there. They got captured. I lived with my father, the retired Army officer, during the war.

INTERVIEWER: When were you born?

MR. BARTH: I was born on August 28, 1930.

INTERVIEWER: Your parents separated and your mom stayed behind?

MR. BARTH: My parents separated in the late thirties. They divorced in about 1937 or 1938. My mother was the manager of the Hamilton Brown Shoe Store in downtown Manila until just before Pearl Harbor was attacked. I got out because they were taking kids out.

INTERVIEWER: They were taking the dependents out.

MR. BARTH: I got out and came back to the States.

INTERVIEWER: How old were you when you left Manila?

MR. BARTH: I was eleven.

INTERVIEWER: What are your memories of Manila, when you were very young?

MR. BARTH: Oh, going to school and places I hung out are memories. We lived right near the 'Army-Navy Club,' as it was called in Manila. If anybody is familiar with Manila some years ago, the American Embassy was just south of a group of buildings called the 'Army-Navy Club,'

and I hung out there as a kid. It had a swimming pool. You don't talk about what other kids remember. I remember being a child in those days. I remember things we did. I certainly don't remember every single day of it, but some things.

INTERVIEWER: Did you go to that all-American school, or an English speaking school?

MR. BARTH: Sometimes, I did. Other times, I didn't. We moved around a little bit and lived in the country and in the city. Schools were probably mixed. They had English-speaking schools, of course, and they had two that handled me.

INTERVIEWER: Do you remember any teachers or anybody who had an influence on you?

MR. BARTH: Not a one. I don't remember any of my teachers from high school.

INTERVIEWER: Well, you just preempted one of my other questions then. What can I tell you? Never having been in the Philippines, I'm asking some of these questions. They're interesting for me, as I'm sure they will be for other people who listened to your whole history interview. Was there a feeling that there was something amiss because people were leaving? Was there was a conscious effort to somehow dodge a bullet that might be coming?

MR. BARTH: You know, nowadays, we watch the evening news every evening and find out what's going on in the world. In the late 1930s and early forties, we depended solely on maybe an occasional radio transmission. But everybody who lived in Manila, and I remember this by people talking about it years afterward, knew the war was coming, without a doubt. There was a two-year, or maybe a three-year period, and perhaps it was even greater than that, that we expected the war with Japan. We just didn't know where it was going to start. There was a mass exodus of people who could leave, wanted to leave or were told to leave. The Philippine Islands belonged to us back in those days and there were a lot of American companies there. The same amount of representatives from a company or a group of companies today were people who lived in Manila. They were companies like Colgate Palmolive and the people that made 7-Up and Pepsi-Cola. My stepfather, who wasn't my stepfather at the time but was after the war, was a manager at International Harvester, for example. Yes, we knew. I won't say, 'we,' as though I am

including myself, because I was an eleven-year old kid. But it was common knowledge that the war was about to happen.

INTERVIEWER: Do you remember any circumstances surrounding your evacuation, like what it was like, what it felt like, or what happened?

MR. BARTH: No. Being an Army brat, I was able to get a ride back on an Army transport. They arranged that somehow. I wasn't involved with that. I said goodbye to my mom. She gave me five dollars, and I went aboard the Army transport, but there were a lot of civilians, a lot of military dependents and a lot of kids my age. I happened to be by myself, but there were friends on the ship who looked after me. I bunked in a room with their kids and came back to San Francisco via, I think, Wake and Honolulu. I came into Manila and was met by my dad.

INTERVIEWER: Was that in San Francisco?

MR. BARTH: Yes. That was in San Francisco.

INTERVIEWER: You managed to arrive in San Francisco before the attack Pearl Harbor took place?

MR. BARTH: Yes, by about three weeks. It was something like that.

INTERVIEWER: Your dad was stationed in San Francisco?

MR. BARTH: No. He was there to pick me up. He had just been called back by the Army. He had retired once from the Army. My pop joined the Army in something like 1909 or 1910, or something like that.

INTERVIEWER: He was a World War I veteran?

MR. BARTH: Yes. He did forty years in the Army, I guess, but they had called him back in because World War II about to happen. He came and got me and then, we went off to some new assignment to which he was going. I don't remember quite where it was now, but I spent the war with him in various locations because he was back in the Army. During the last year or two of World War II, I was living in San Francisco. He was a troop ship commander. He would ride troop ships over and back and be responsible for the soldiers. He was gone and I lived with my

stepmother. We lived in a marina district. I went to Marina Junior High School down there, which is now called something else, but I was there when the war ended, as a matter of fact, in San Francisco.

INTERVIEWER: You don't recall any teachers?

MR. BARTH: I don't remember teachers, no. I don't remember names. I have a face of my shop teacher in my head. I remember him because he had a part-time job in the shipyard. Kaiser was across the way over there, in Sausalito or wherever it was. He had an evening job and was doing some work with a piece of steel and cut the fins of his thumbs off. He came back and told us, "This is what will happen if you're skylarking while you're working heavy equipment," and I remember that.

INTERVIEWER: I figured you might. You went to high school in that area, I assume, also?

MR. BARTH: It was called 'junior high.' Then, the prisoners who were held by the Japanese, American civilians, in the final years of the war, were held in a university campus outside of Manila called Los Banas, and that was where several thousand of them were kept. I think they did two years there, the last two years. The American Army parachuted in one Sunday morning, a whole flock of these guys, out of airplanes with some trucks, 'Amtracks' they called them, I believe, and got all the Americans. They had to fight their way out of the camp. They took them down to Mindenow, eventually. Because there was still a lot of fighting going on in the Philippines, they put all of them on the transport ship, which brought them back to the States. That was just before the war ended, but I couldn't tell you exactly when it was. I was living in San Francisco, so I met the transport ship. My mother and my future stepfather were on it. I stayed with them at the Palace Hotel in San Francisco for a few days, as a matter of fact. They went back east and I joined them in December of 1945 in Chicago. Chicago was the corporate headquarters for International Harvester.

INTERVIEWER: I'm glad to hear your mother survived.

MR. BARTH: She did pretty well. She held off until 1974, I think, when we lost her.

INTERVIEWER: I was just going to ask whether your mother was interned at Santo Tomas and then Los Banos.

MR. BARTH: She was at Santo Tomas first, if you're familiar with it. They all went to Santo Tomas first, and I think they were in there for the first year and a half, of the three and a half-year internment. The last part was at Los Banos, but it could be the reverse. They're not around anymore to be asked that question and I'm sorry that I didn't learn more about what they did, really. As a kid, you have a tendency to not even talk about things like that. Now, they're all dead and I have no idea what three-quarters of the things that I can remember, stories that they told, but not day to day, month to month type --

INTERVIEWER: Your mother never talked about the rescue?

MR. BARTH: Yes, she did. She talked about it. I was talking about it last night. The subject got onto that. Perhaps you're familiar with the old World War II after barracks. There was a long barracks with people on both sides of the barracks. Everybody had a little cubicle. Her cubicle was right at the end of one, near the door. Airplanes had been flying over the camp for quite some time, going from here to there.

As a matter of fact, one of the pilots was shot down and it crashed near the camp. The Filipinos sneaked him into camp and the Catholic priest, as a priest, kept him in a safe area and hid him until the war ended. The Japanese didn't know that he had been a pilot. But the morning that all these airplanes were flying over and there was a lot of parachuting going on, there was a lot of fighting going on in the camp, and my mom said that the door flew open and a Japanese soldier ran through the door. She was under her bunk by that time with her footlocker pulled over because she was afraid of ricocheted bullets or shrapnel or whatever might get her.

The Japanese soldier opened the door and ran about 15 or 20 feet inside the door. They always talked about the American soldiers, the ones who looked like they were seven feet tall and well fed, because all the men in the camp were fairly run down. The American soldier ran through the door and shot the Japanese soldier. He was sprawled out on the floor. The whole

barracks was full of women, and they were all screaming and hollering. The soldier stood there and told them to shut up. Then, he said, "I'm looking for Mrs. So and So and her daughter, Mary," we'll call her. They said, "She's in the other barracks, the next one over. Why are you looking for them?" He responded, "I'm her son. I volunteered for this mission. I came to get my mom and my sister," and he did and he got out. That's one story my mom told me that I've always remembered that because I think it's a neat story.

INTERVIEWER: Oh, yes. It is a neat story.

MR. BARTH: They fought their way out of the jungle and all that junk that goes with it and eventually made their way to Mindenow, I think. I'm not sure.

INTERVIEWER: At what age did you enter the Navy?

MR. BARTH: I was seventeen.

INTERVIEWER: My father went in at seventeen, also. Did you join in San Francisco?

MR. BARTH: No. I was living with the man who became my stepfather. He had come out of camp in the Philippines and gone back to Chicago with International Harvester and I went to live with him. We lived in Chicago, or at least I did, from December of 1945 until around July of 1946. I went to Lane Technical High School in the north end of Chicago. By then, he had received his new assignment and was going to be South Africa. We went and got on a Robin Line ship in New York, C-2. You didn't have steamers or airplanes flying around a lot in those days, and we went to Durban, South Africa through Cape Town, Port Elizabeth, and East London. I was living in Durban when I turned 17. I was the only American kid in town, except for a gal about my age, and I was 15 or 16. When I turned 17, I was able then to leave Durban on my own. I came in on their visa as a 15 or 16 year old and was unable to leave. I didn't like it there. I was an American but hadn't lived in the United States for very long, maybe only four years. I was anxious to get back and become an American again. When I turned 17, I arranged with the American Consulate in Durban to prepare the paperwork, unbeknownst to my parents, so that I could leave. Durban was a big seaport. When I turned 17, I skipped school and went

down to the waterfront and found an American ship that would let me work my way back to the States. I went aboard that ship and signed on. I went back home that night and told my parents what I had done, and needless to say, they weren't too pleased about it. But I signed on board this merchant ship. We had to go all around the ocean first. It got me back to States at the end of the year, in November, and I joined the Navy then. I joined the Navy in Chicago.

INTERVIEWER: Can you describe what Durban looked like in those days? You said you didn't like it. What was it about it that you didn't like? Was it simply because you wanted to be more acclimated to America?

MR. BARTH: No. I was in high school ---- and I was the only American kid in high school. I didn't get along too well with people and the guys, in particular. The girls thought I was different. They didn't go to school with an American very often. I went to school and did more fighting in school than I did studying just because one kid or another didn't like my existence, or my being there, but that's beside the point. I just wanted to get back home. I couldn't leave without working my way home.

INTERVIEWER: What was it like, working on a merchant vessel at the ripe old age of 17?

MR. BARTH: It was different.

INTERVIEWER: That's why I asked you.

MR. BARTH: It was different. It was just on a voyage. We went all the way up the east coast of Africa and went from Durban to several other seaports that are no longer the same countries. They have different names now. We went all the way up to India, came back down around and as a matter of fact, went over to Brazil. We stopped at Racifi in Brazil and then went on back to the states. As a matter of fact, we came here, to Baltimore, or close to here.

INTERVIEWER: You came into Baltimore?

MR. BARTH: Yes.

INTERVIEWER: You then went back to Chicago?

MR. BARTH: I went to Chicago because that was where we had lived before we left and the only people I knew in this new life were there, not my pop out on the west coast. My dad was in San Francisco. I went back to Chicago and went to the same apartment complex that we lived in before I left and saw those people. They kind of looked after me. I met the Navy recruiter, who eventually recruited me into the Navy. I lived in the same apartment complex and joined the Navy. I went to Boot Camp in Great Lakes.

INTERVIEWER: Was the Navy attractive to people because it wasn't the Army, or was there something else about the Navy?

MR. BARTH: Oh, no. I just thought sailors had a heck of a lot more fun. I remember that when the war was over and I was living in San Francisco, I went downtown and celebrated with everybody on V-J Day. I remember a sailor. He had a hat on the back of his head with a girl under each arm. I said, "That's for me."

INTERVIEWER: They should have made him the poster boy, right?

MR. BARTH: Yes. I always liked things involving the water and the ocean and things like that. Even as a kid, I was interested in what went on under the water and things like that. I was certainly not going to find that in the Army. I had been born in an Army hospital and raised on Army posts. I had really a good knowledge of Army posts and was pretty sure that that was not what I wanted to do.

INTERVIEWER: When you entered the Navy, what did you intend to do with it, or did you have any immediate plans?

MR. BARTH: I had no idea. What seventeen-year-old knows what he wants to do?

INTERVIEWER: Very few.

MR. BARTH: Yes, very few.

INTERVIEWER: What do you recall about boot camp? What was your first experience like with the real Navy?

MR. BARTH: It was cold.

MR. BARTH: I mean, the Great Lakes in the winter aren't warm. That's what I remember about it.

INTERVIEWER: What was boot camp like in those days? What did they put you through?

MR. BARTH: That was 54 years ago.

INTERVIEWER: I know.

MR. BARTH: I don't remember a lot about it. I got out of boot camp and they called the place where you went to the Navy, the boot camp area was 'Outgoing OGU,' or outgoing unit, and you waited for your orders. My first orders, along with 29 other guys, was to Port Wynemi to be a Seabee, and I hadn't joined the Navy to be a Seabee.

INTERVIEWER: That was something that you selected.

MR. BARTH: No.

INTERVIEWER: That was something you were just simply given?

MR. BARTH: Yes. I joined the Navy to ride a great big thing with white numbers on the front of it, but I was a construction electrician school candidate and for a month or so and was in construction. Those were the guys that climbed telephone poles. I found myself with those little funny spikes on my shoes, climbing poles, and I liked that even less than living in Durban, South Africa. I complained, complained and complained. They finally said, "If you want to go to sea, go to sea." They put me on an aircraft carrier.

INTERVIEWER: Which one was that?

MR. BARTH: It was the USS *Boxer*, CV21, in San Diego, where I stayed for the next four years.

INTERVIEWER: Which four years were they? Do you remember?

MR. BARTH: 1948, 1949, 1950 and 1951.

INTERVIEWER: What was the *Boxer* doing while you were on board?

MR. BARTH: It was flying a lot of airplanes. We had the Korean War come out two years after I got on board. I did two or three tours there, on the carrier. Then, I had visions of becoming a civilian again, so I got out briefly and then came back in.

INTERVIEWER: What were you doing on board the carrier?

MR. BARTH: I was a signalman. I was a signalman striker and made third class. But they had phased out the signalman rate at that time and all signalmen were quartermasters. Quartermaster signalmen were quartermasters, also, but the 'job code number,' as I think they called it, was different. You could tell if a quartermaster was a quartermaster or a signalman quartermaster, but that was what I was, a signalman.

INTERVIEWER: Did you get out briefly because you were disillusioned with what the Navy was supposed to be?

MR. BARTH: Oh, yes. What 21-year-old doesn't spent four years in the Navy and doesn't think about getting out. It wasn't until you got out and realized you were going to starve to death because you don't know anything but what the Navy taught you. You said, "Hey, it wasn't such a bad place after all." I came back in. The Navy always looked good to a guy on leave because he went home off the ship and got thirty days leave. He got a handful of money and while he was there, they sent him another check, which was another handful of money. He got up at ten in the morning. He stayed up until four in the morning. He didn't have a responsibility because he was just on leave. The outside looked like a darned neat place until you got out and had to get up early in the morning and go to work. I found out right quickly that the outside world was not for me. I didn't have a hometown to go to, so I ran around with a guy who was from Coffeetown, Kansas. That's a little town down in the southeast corner of Kansas. I had gone on leave to his house. You know, like anything in the Navy, when your ship came in for an overhaul or some time off after a long cruise, everybody took off and went on leave. Well, my parents at the time were either living in Nairobi or Singapore. It depends on what part of that four-year period we're talking about. We didn't have 747 service then, so I went back to Coffeetown with him. I met this lady, fell in love, which was easy to do on a thirty-day leave, by the way, when you had a pocketful of money. I got out in '80 and married her, stayed there a while, and didn't like it and then got back into the Navy. Eventually, I got divorced and stayed in the Navy until I retired.

INTERVIEWER: When you went back in, you obviously weren't sent back to your carrier.

MR. BARTH: No.

INTERVIEWER: Where did you go?

MR. BARTH: I was sent to the Fargo building in Boston, which was a receiving station. I waited for an assignment. I was assigned to new construction. The USS *North Hampton* was a cruiser. It was a CLC. It was a unique ship. They only made one of them. It was a technical command ship. The president could embark on it if he needed to. It was put in commission in Boston at the Charlestown Naval Shipyard.

INTERVIEWER: Did you use your electrician's background in that work?

MR. BARTH: No. I wasn't a electrician. I was a quartermaster.

INTERVIEWER: I thought you had some electric background?

MR. BARTH: No, no. I was a seaman by that time. I was still a quartermaster. I worked there for a while and was then assigned to another ship, a DER, the real hoy DER 397 out of Charleston. They put her in commission and I had been fighting to go to submarine school for some time. Finally, I got a set of orders for sub school. I went to sub school in the early part of 1955.

INTERVIEWER: What was attractive about subs? Why did you decide to go after that?

MR. BARTH: I was on a cruiser and in Boston. There was a submarine in there one day. It was in Boston, I believe. There was only a small bridge on a fleet boat. A guy off the ship started jiggling me, which means that you give J in semi-four and want to send semi-four. I responded and we started sending semi-four back and forth. I didn't get to talk to many people, but semi-four was something I wanted to practice. We talked, periodically, for the next day or two, and I said that I'd never been on board a submarine. He invited me over and I had lunch on that submarine, where they actually let you sit down and you were served. They put a pitcher of cold milk on the table. I never had somebody put a pitcher of cold milk on the table on big ships. You got a bowl full of milk when you went through the chow line. I said, "This is great." Then, they went to sea and I wrote him, "That's it. I want to go to submarine school." I did, eventually.

INTERVIEWER: They sent you to submarine school in 1955?

MR. BARTH: I went to sub school in 1955

INTERVIEWER: Was that in New London?

MR. BARTH: It was in New London.

INTERVIEWER: What was it like?

MR. BARTH: It was like any other Navy school. It was time consuming. I had to try to stay awake. It was interesting because sub school wasn't your typical place, where you sat in class all day. You got out and did things. It was interesting. I don't recall a lot about it, but I went through the escape training tank in New London. I was fascinated with the work that they did there. There's only one training tank left in the world and it's not used anymore with water, but they had a tank with a 120 foot tall column of water, 18 feet across, and I was fascinated with that and watching those guys work. Eventually, some years later, I was eligible for shore duty. I had gone to diving school a couple of times already, so I put in for shore duty at the training tank and got it. I was stationed there when I got involved with saturation.

INTERVIEWER: Not very many people can say they've been up to the training tank at sub school. What was it like, doing it for the first time?

MR. BARTH: It could have probably been very alarming if you were not a water person. A lot of guys have put their heads underwater and done strange things and in particular, held their breath. I didn't have a fear of the water. The only sport I ever did in high school was swimming. I didn't play football or baseball much. I was fascinated by watching those guys work and couldn't wait to get there and learn to do the things that I had seen them do. You went through a learning curve because there was a lot of breath holding that took place at the tank, and I did learn. I got there in January of 1960. I mastered the details of having to be an instructor and that was where I worked for the next four years.

INTERVIEWER: Before you got to the tank, however, I assume they sent you out on a sub after school?

MR. BARTH: I was assigned to a submarine in Key West and then, that squadron left town and I was assigned to a second submarine and then, I went to the tank. I rode two submarines in Key West.

INTERVIEWER: Which two were they?

MR. BARTH: One was the USS *Guavina*. That was AG or AOSS 362 and then, I don't remember. I think they were getting transferred to Charleston or something and I transferred over to the USS *Quillback*, 424. From the *Quillback*, I went to the tank.

INTERVIEWER: What role did you play on board the subs?

MR. BARTH: I was a quartermaster.

INTERVIEWER: The tank was a break, wasn't it? It was something outside the quartermaster world?

MR. BARTH: Oh, yes. I had gone to diving school earlier. I had gone to diving school back in 1949. I later went to this one school in Key West in 1958.

INTERVIEWER: Were these efforts on your part to add to your skills?

MR. BARTH: It was something I wanted to do because the Navy was full of neat things to do. All you had to do was pick one out and try to get to go to it. You could sit around and let BUPERS dictate your whole Navy career or you could branch off and go do things. The only way to get things out of the Navy is to just try them all. I tried as many as I could.

INTERVIEWER: There you go. You said the diving school was in Key West?

MR. BARTH: The Navy School of Underwater Swimmers was. It was a SCUBA school, you know. For years, divers who went to dive school learned with the old Mark V hard hat shallow water mask and so forth, but there wasn't a lot of SCUBA.

INTERVIEWER: It was fairly new then, wasn't it?

MR. BARTH: It was fairly new and was not well accepted by the Navy divers, to be quite honest. Talk to a guy who's been around a heck of a lot longer than I have and he could vividly

remember how they were sent this 'newfangled' stuff, as we called it, and they never used it. They would just stick it up in storage. The conventional Navy divers, in those days, were used to breathing through hoses. The thought of just carrying a limited supply on their backs was foreign. They had no communication, in some cases, and didn't always have shallow water stuff. SCUBA gear wasn't popular, but it became, over the years, the most popular tool the military diver had, but it took a while.

INTERVIEWER: What was your impression of it when you first tried it?

MR. BARTH: Well, actually, I was fascinated with it because it enabled people to go out on their own, and I had actually gone out SCUBA diving. I had been a second class diver for a number of years, so I went out with Navy guys who had their own SCUBA equipment. I learned to like it. I thought it was great. You sure had the mobility. Underwater in the Florida Keys is interesting. I just put in for it. The *Guavina*, at the time I was on it, was a tanker submarine, and it worked with seaplanes, like the old P5M flying boat, the one with the gold wings and two piston driven air engines on the wing. We occasionally had to do things underwater that I took that chore on, as far as fueling the seaplanes and so forth went. I could go to school. I put in for swim school, and I got it.

INTERVIEWER: Swim school and diving school were different?

MR. BARTH: In swim school, we were only taught SCUBA.

INTERVIEWER: I see. Diving school could still be considered the hard hat years?

MR. BARTH: Yes. It was.

INTERVIEWER: You did that, as well?

MR. BARTH: I had done that before. I had done that in Pearl Harbor in 1949.

INTERVIEWER: Again, was it because it was something that you wanted to do?

MR. BARTH: Yes. Everything that I ever did in the Navy, as I recall, was because I wanted to. I wasn't shanghaied to do anything. There might have been a few guys out there who wanted to get rid of me, but they never really tried too hard.

INTERVIEWER: What was interesting about the tank? You said you found the work that they were doing there interesting.

MR. BARTH: Well, you were looking at a column of water that was 120 feet deep. It was 92 degrees in temperature and as clear as any swimming pool. You were doing training with submarine school candidates or submariners who were back for re-qualification. It was just breath holding. Most of it was breath holding and I just thought it was just swimming around the pool, diving down, holding your breath to forty, fifty, sixty, or 120 feet. I just thought that would be a neat thing to learn how to do, so I put in for it.

INTERVIEWER: How did they teach you to do that well? What were you told to do?

MR. BARTH: They stressed repetition. You saw other people doing it, so you knew that it was possible, and you wanted to do what they were doing. You were somewhat fascinated by a guy who could take a breath of air, kick off and post down to the bottom of the training tank. He might have taken his shoes off before he left and thrown them in the water and watched those shoes go down to the bottom. Then, as they hit the bottom, he took a breath of air and dove down and picked up his shoes very carefully and not in a big hurry. You were holding your breath on the surface at 100, 120 feet. Then, he put his shoes back on and tied them and he made sure that they were just right. They'd do that as a demonstration. They'd come back up a couple of minutes later. I said, "Man, I want to do something like that."

INTERVIEWER: How long did it take to do that?

MR. BARTH: Oh, you probably had the ability within the first year. Your lung capacity had to be improved. You had to be able to pull in a lot more air. You had to be able to blow out a lot more air. Your residual capacity and total capacity grew. You held your breath for, say, six hours a day, taking breaths, holding them, and taking breaths and holding them. If you lifted weights for six hours a day, you can imagine how muscle-bound you'd be. Your lungs developed that kind of ability. Then, you knew that when your lungs were hollering for you to take a breath, you

didn't need to. You could hold it a little bit longer. Those things, you wanted to learn. Have you ever seen somebody do something that you wanted to be able to do?

INTERVIEWER: Oh, yes. While you were doing this, you encountered some Navy people who were working on deep submersion.

MR. BARTH: It wasn't called 'deep submersion.' We didn't even have a name for it. It was Dr. George Bond, who has been dead now for some years, a Navy doctor. He was an old country doctor from around Bat Cave, North Carolina, who came into the Navy after years of practice there. Dr. Bond worked at the Submarine Medical Center, at the submarine school. The role of the doctors at the medical center was to assist us. We had to have a doctor on the scene. Dr. Bond was one of these doctors. Dr. Charlie Aquadro was there, along some others, and they all worked the Submarine Medical Center.

I met Dr. Bond, but I had met him a few years before when he and a fellow, a chief engineman by the name of Cyril Tuckfield, were working together. That was during the development of the buoyant ascent jacket. It's different now, but the way you got out of a submarine in the old days was to put a jacket on. You inflated it, got out of the submarine and went to the surface, exhaling all the way. It was called 'buoyant ascent.' Dr. Bond and Cyril Tuckfield had done buoyant ascent off the USS *Archer Fish* in 1958, I think it was. I had gone to swim school with one of the guys involved with that. I had met Dr. Bond then, and I went to the tank. Of course, I met him again. He had been embarked on a program called 'Genesis.' Genesis was an idea that he and Jacques Cousteau formulated in 1957. They were at a Boston Sea Rovers conference and put together everything they had. It still happens every year. He met Cousteau and they became good friends. Cousteau had his conch shell program, Habitat in the Mediterranean, back in the late fifties, and early sixties. Cousteau did not know a lot of things about the physiology involved in 'saturation diving,' as we call it today. We had the knowledge that we could dive with helium. We had been diving with helium for years, but just on a dive basis, in which you go and come up some time later and decompress.

Bond was interested in finding out what. Of course, he was prompted and motivated by Cousteau's questions. They agreed that they would exchange that information. Bond went back to the Submarine Medical Center and embarked on his studies to see if we could do that with people. He started with animals, but eventually got to people. From 1957 to the early part of 1962, we used nothing but animals. I was there and helped just because I was interested.

Bond was a unique guy. He always had ideas, and there wasn't a guy who worked with him who didn't feel that any idea he had was worth getting into. I got involved with him, but not up on the hill at the Submarine Medical Center. We had an old chamber down at the training tank, which was on the waterfront in New London. He brought a bunch of goats down. We could get goats easily because we kept them on the other end of the base. We had a storage area for explosives. It was grassy and we kept goats there to keep the grass down. The respiratory system of a goat, I am told, is somewhat similar to the respiratory system of a human, or at least close enough to conduct studies on them so that you got some useful data relevant to human beings. We saturated goats.

By that time, it had been about five years since they had started. All the data that they collected, all the way up from guinea pigs, mice or whatever they used in the lab, had proven that it looked like a viable thing to put people under pressure, breathing helium for long periods of time. That was what saturation was all about. They thought it would work.

Then, I worked with him on the goats for a while. He got permission from the Navy after showing the Navy all the data. He said, "Look, I've got five years of this stuff and it looks good." He had to convince everybody that it worked.

INTERVIEWER: Up to that point in time, you were volunteering for something, weren't you?

MR. BARTH: Yes. I was still at the training tank. I could have just been released from the tank to go TAD somewhere. Two other doctors and I went down and were put in the chamber. We were in there a week, I think, but there was no pressure. We flew the chamber and pulled the

vacuum and brought it back down to the pressure equivalent to the earth's surface, or sea level pressure.

INTERVIEWER: Now, which chamber is it that you are talking about?

MR. BARTH: It was the helium and oxygen chamber, but it was just an old one in Bethesda, at the Naval Hospital. He didn't want to have to be burdened for days on end with decompression if we had a problem with people in helium and oxygen. If we had a problem, we could open the door and walk out. You couldn't do that with diving. You had to take decompression.

We did the first one in November of 1962 in Bethesda. It was three of us in a chamber. We stayed there a week, and there was no pressure but helium and oxygen. It worked fine. Then, we got permission. Bond showed them the data, got permission to go to the next phase, which was Genesis something or other. I don't remember. It was Genesis C or D or whatever. We went to the Navy Experimental Diving Unit (EDU), which, at that time, was at the gun factory in Washington, where the school was. Two corpsmen and I did a one hundred footer.

INTERVIEWER: Only this time, it was in the water?

MR. BARTH: Well, there was water in the chambers at the EDU. It had a small chamber below it, into which we could put water. But that wasn't what our purpose was. They were physiological studies to find out if you or I could live in a helium atmosphere under pressure. We did it for a couple of weeks, I think.

INTERVIEWER: Why did you think it was worth pursuing? If you could live in a helium-oxygen atmosphere, then what? If the answer is yes, where did you go from there? Where did Dr. Bond want to go with that?

MR. BARTH: We didn't have a goal, necessarily. We were taking each step, one at a time. You didn't go to the Navy and get approval to get all the way to the end of it. You got approval to go one step at a time and that was what we did. We were trying to convince ourselves and the powers that be that we, in fact, could put people in a chamber, take them to depths and leave them there. That eventually led to saturation diving, as we know it today. Why do we have

saturation? We can take people today and put them in an environment, a saturation system. We can put them in a bell or in a habitat, like SeaLab, at the bottom of the sea, where they can stay. We know that. We proved it in the chamber runs that you can breathe helium for long periods of time. Breathing helium at the bottom of the ocean is no different, but you're at the bottom of the ocean. You stay there. Where could we breathe before we had saturation? We were limited to the 300 to 400 foot range. Granted, there were times when we, at the EDU, for example, and some other research facility, would go down to 400 and 500-foot range, but we didn't do much saturation. We made an excursion run and ran down to some particular depth. Let's say it was the 400-foot range, for a nice round number.

At the 400-foot dive, it required a 350-foot dive, as I recall, for an hour. It required several hours of decompression. How long could we have kept that up, and how much useful time could we get on the bottom? Now, I can turn right around and put a man in a saturated mode out of a bell or out of a SeaLab, put it on the bottom, and leave him there for a three months at depths in excess of 2,000 feet. That's our capability today. We increased our depth capabilities to around the 2200 or 2300 foot range and are able to stay there, whereas before, we could never get to 2000 feet. The only guys who ever went to 2000 feet stayed there. We never saw them again.

INTERVIEWER: Genesis was designed to establish the capability?

MR. BARTH: It was designed to do the physiological studies. We did the first and second ones at the EDU and a final one at the submarine base in New London, where he was, the officer in charge, Bond, was a the Submarine Medical Officer.

We did what was scheduled with a three-week, 200-foot dive. One of the guys from the second Genesis, one of the guys from the first Genesis, a doctor and a hospital corpsman and I did it. I think it was close to three weeks at 200 feet. When that was over, we had shown the Navy we could, in fact, put men under pressure and leave them there. Then, we went into the SeaLab mode after that.

INTERVIEWER: Before you move on to SeaLab, I think that it's important for historians, who want to understand what people were like, to know a bit more about personality and appearance and all the rest, because the whole picture is better than half the picture. Can you describe Dr. Bond? What did he look like? What were his mannerisms?

MR. BARTH: He was a big guy. He was friendly. He had the kind of face and the personality to which you just took. There wasn't a guy who didn't love him. If he said, "Let's go to the moon," they'd have been fighting to get in line to go with him. He would do anything that you asked him, or he would ask you to do something that he could do himself and generally, you had to fight him for the chance to do it because he'd be in the water doing something.

We were at the training tank together. It was him and I and other guys. By the way, it was not just Bond and Barth who would do the demonstrations. We would come in the evening and the submarine officer's class would bring their wives down. We would show them all these neat tricks. I would cover for Bond on the tricks he'd do. There'd always be somebody in the water who would help the other guy.

INTERVIEWER: What sort of tricks would you do?

MR. BARTH: Well, Bond did a very fast free ascent. In a free ascent, you used the volume of air in your lungs as a buoyancy factor and exhaled as you came up. You kept safe by exhaling so that you didn't embolize, but you kept enough air in your lungs to keep that upward momentum. Bond did that.

We used to take a bucket down with us, and we had a little blister stuck on the side of the tank down below, at the 85-foot level or 100-foot level. We would empty the water out of the bucket and put the bucket over our heads and use it as a buoyancy factor. He'd step out in the water and do a buoy ascent with a bucket.

We'd also take a pair of Levi's pants, or whatever, and put them over our swim trunks. We'd swim down to the 100-foot level and take our pants off and tie them in a knot like they taught you, to hold you afloat while you were at sea. We'd put our heads up inside the pants,

which were full of air, and do them free. We just did foolish junk like that. We also made bottom drops, going down to the bottom and so forth.

INTERVIEWER: Now, to the ordinary person, that might not seem to be fun, right? Why was it fun for you?

MR. BARTH: I don't know. That's a tough question. I was a water baby. I just liked the water. Gosh, you wouldn't be an instructor in the training tank unless you really liked the water and got to do those things. You had no business being in there if you didn't like the water. People who are scared of airplanes don't become pilots. It was just something neat to do and that was all, really.

INTERVIEWER: Was it not until the first SeaLab began that you were actually officially attached to a project and working it full time? It seems that up to that point in time, through the various stages of Genesis, you had a full-time job at the tank.

MR. BARTH: Yes.

INTERVIEWER: Occasionally, you got permission to do these diversions?

MR. BARTH: Then, we'd get TAD from the tank. We were still TAD, but by that time, my tour was at the training tank and I knew I was destined to get into the SeaLab program. But the program was just somebody's idea that was tolerated by a few in the naval hierarchy. Few people knew about it. I went back to a submarine in Key West and Bond kept pulling me off to go up to TAD, where we were, at the time, building SeaLab I in Panama City. That annoyed the heck out of my commanding and executive officers on the submarine because I was a chief quartermaster at that time. He said, "I've got a chief quartermaster and he never rides in the boat."

We did SeaLab I in 1964. Everyone who was in the SeaLab program was TAD from our respective commands. It wasn't until January of 1965, prior to SeaLab II, that we were pulled in as a permanent entity. That was in January of 1965. We stayed that way until the end of the program.

INTERVIEWER: What role did you play in SeaLab I? What were the tasks that Dr. Bond assigned you?

MR. BARTH: By that time, I had three saturation dives in chambers to my credit. It was really physiological information data, not credit. They had a lot on me, so I was selected to be one of the four guys who were going to be in SeaLab I. One of the others was a guy who had done two of the Genesis programs with me.

INTERVIEWER: Do you recall his name?

MR. BARTH: Yes. He was 'Tiger' Manning, or Saunders Manning. He was chief and then the senior chief corpsman. He lives in Georgia right now but is generally home in Missouri. When we both got out of the Navy, he and I worked together at Taylor Diving and Salvage in Belle Chase, Louisiana, some years later. Tiger and I and two other guys were on SeaLab I. We built it, tested it, took it to Bermuda, put it on the bottom in 193 feet of water and lived in it for eleven days. It was scheduled to be longer than that, but it was during the summer.

INTERVIEWER: Was that because of a hurricane?

MR. BARTH: It was because of a hurricane.

INTERVIEWER: You're inside Sealab I. Look around. Tell me what you see.

MR. BARTH: I see a round tube, similar to one you might find if you lived in an air-streamed trailer and were camping. I don't even remember the length of the doggoned thing now. It's big and comfortable, for four guys. The bottom of the ocean has the water as clear as the water in a swimming pool. The water temperature is in the eighties. We have four portholes, two on each side and, of course, the entranceway on any habitat is through the bottom. You don't have doors. You open it up. You have to go out the bottom. It's the equivalent of taking a glass, an empty glass, and holding it, trapping that air. That's what a habitat does. We lived in it and were free to come and go as we wanted. We could turn the lights out in it and read a book from the light coming through the portholes.

INTERVIEWER: Was it coming through the water?

MR. BARTH: It was coming through the water from 200 feet up, or thereabouts. We had good times. Probably the best project, out of everything I did, was SeaLab I. We weren't fully recognized as a group by the Navy. They thought we were a bunch of blockheads who eventually were going to do something incorrectly and kill ourselves. They didn't want to be any part of that. They were always hiding behind trees until we were successful enough. Then, they came out like termites. But they left us alone and we did just about whatever Dr. Bond wanted us to do. We drew blood. We put other body fluids in bottles and sent them up to him. We did all the tasks and were then allowed to go outside and play.

INTERVIEWER: Was the hatch constantly closed?

MR. BARTH: No. It was constantly open. We had a hole in the floor. Actually, it wasn't just a hole in the floor. It was a hole in the floor, but it had a tube that came up.

INTERVIEWER: The tube was hollow.

MR. BARTH: We had a lot of rise and fall in terms of the water level, so that tube went outside and extended below the habitat itself, which was a cylinder. It came up about, I don't know, three feet or so. It had a ladder going up and down. The hole was just about three feet squared or maybe a little more. When you were ready to go outside, you could look into it. It was a hole full of water. We'd just put on our gear and go outside.

INTERVIEWER: Once you were in the habitat and came up through the opening in the floor and were up above that level, it was a regular environment in which you could change your clothes? You could shower.

MR. BARTH: Exactly. It was no different than going camping in a motor home or trailer or whatever. It was just a haven, really. It trapped the air that was in it. We scrubbed the bad out of the air, the carbon dioxide (CO<sub>2</sub>). We added oxygen, as it was needed. It was a helium-oxygen mixture. We would add oxygen when we needed it and scrubbed CO<sub>2</sub> when we needed to do that. It was warm outside and very comfortable. We couldn't cook in it, though. We ate out of

cans. We had a refrigerator, but it broke. We kept our shoes in it, actually but never used it. We just ate out of cans. It was great. I'd do it again today, if we could do it.

INTERVIEWER: What about sanitary facilities? What kind of a toilet did you have?

MR. BARTH: Have you ever been aboard a boat?

INTERVIEWER: Yes. It's the same as just a flush head.

MR. BARTH: You sit down, do your business and then pump it. That was all we did. It went outside to a penetration below the toilet, just like on a boat. It went out and off the side of the boat. We just had a hole in the side of the habitat, but we had a pipe stuck in it. I think it was a non-collapsible hose. When we got to the bottom, we screwed it on there, just like you would a fire hose on a fire hydrant. We then laid it out on the bottom somewhere. The environmentalists would have a field day with that now, maybe, but that was the way we did it.

INTERVIEWER: You were all still breathing this mixed gas that was mostly helium? You were speaking 'helium speak?' You were all talking the same way? Did you all have trouble understanding each other?

MR. BARTH: Yes, with some words, maybe. The deeper you get, you know, the more pronounced that helium distortion becomes. Two hundred feet is not bad. We didn't get into lengthy conversations about Einstein's theory of relative humidity or something. We avoided some of the stuff. We found some words that we just didn't use at all. Swear words were always very intelligible. We could understand them anytime, so we swore a lot.

INTERVIEWER: That's the one thing helium can't defeat. You were down for, you said, eleven days?

MR. BARTH: Yes.

INTERVIEWER: You didn't want to come back?

MR. BARTH: Well, no. We raised all kinds of stink about that. We had one guy topside who was a little scared of everything that went on. We kept saying, "Send him home." But they were right. It was very rough and our decompression was based on bringing the habitat up very slowly

and staying in it. It got so rough that we couldn't stay in the habitat. When you're going up and down a dozen feet, you can't maintain proper decompression. You're looking at about one foot every twenty minutes. Decompression from saturation diving is one day for every hundred feet, so we had two days of decompression. We had a hard time maintaining the constant ascent and keeping it exactly like it should have been. We had a small chamber that hung outside. It was just a single lock recompression chamber. We didn't have bells in those days. We didn't have anything around for doing that, so we took a one-lock recompression chamber with the door at one end. We hung it and built a framework on it with weigh. We had that hanging outside, full of air, all the time. As a safety precaution, if something happened inside and we were in a contaminated atmosphere, we could go up inside it.

We went over there and the four of us got into the thing and shut the hatch. They brought it up on deck, maintaining the last 85 or 90 feet that we had to go, and hooked up air to it. We went off helium and onto air and decompressed. They picked the thing up from the level that we got in and I think it was about ninety feet. I'm not sure. We were on a four-legged structure called Argos Island. It was on the Plantagin Bank. It was a Navy listening station. They put us on deck, laid us on our sides, and we decompressed inside of that for the next day.

INTERVIEWER: How big was this container?

MR. BARTH: It was not big.

INTERVIEWER: You got to know those guys fairly well?

MR. BARTH: Yes, a lot more than that.

INTERVIEWER: I assume that since Genesis had established that it was possible, in terms of body chemistry, Dr. Bond wanted to know more. I assume that he wanted to know more about whether you could engage in some sort of activity on the bottom and not only about body chemistry, fluids and all the rest.

MR. BARTH: Yes.

INTERVIEWER: Can you talk about some of your excursions outside the lab and what he wanted you to do?

MR. BARTH: Well, we did things like that before. We didn't just sit in chambers before. During the Genesis experiments, we had programs and projects that we did. To answer the questions that he had about what you could and couldn't do, we'd work hard and get the heart rate up, for example, and see what it was. Everything that we did, although I don't have the medical term, was normal.

When we finally got to the bottom, we could get in the water and go outside. We still had work that we did. We had the physiological stuff, at least, proven. You had to go through it, many years afterward, to get it all ironed out and refined and make sure that you got everything done that you needed to. We had a lot of time to just go outside and go scouting around. They gave us things to do.

INTERVIEWER: Give me an example.

MR. BARTH: We were alongside a four-legged structure. They called them 'jackets' in the industry. Argos Island was a four-legged structure. It was 193 or 194 feet of water deep and had four legs sitting on the bottom. We went out and did work on the legs. We inspected them. We looked at the wells. We did this and that. Not all of the tasks really required us, but we were a great help in completing them. They gave us different tasks to do. We had a lot of cables that came off Argos Island and went over the side of the bank and listened to things underwater. We'd inspect the cables. We were told to scout a certain area. We could organize a sortie from the habitat to 200 yards in that direction, pick up a rock and move it ten feet, put it down and go on back, or something like that. We just did anything that needed to be done. We could go out and do whatever we wanted to do. We would swim around in a radius of about two hundred yards away.

INTERVIEWER: When Dr. Bond was putting this together, since you were as close to being in at the beginning as virtually anyone, were the goals he established solely his own?

MR. BARTH: Oh, yes.

INTERVIEWER: Were other people asking him to do certain select things in order to prove the system, or perhaps sustain the funding, or establish future goals?

MR. BARTH: All of that was happening. He had a staff of people. He had his 'shrinks,' as I like to call them. He had the people who still had physiological questions that they wanted to answer. We were constantly drawing blood. We never did stop drawing blood. You learn a lot from blood, evidently. We learned what it was like to give a couple of gallons of blood over a period of time. There was always something. He had a lot of medical people there.

The psychological aspect of it was something that they looked into, the effects of isolation. The National Aeronautics and Space Administration (NASA) was so interested in the isolation idea that they later put Scott Carpenter down to work with us. Scott would have been on SeaLab I, but he broke his arm and some other things in an accident in Bermuda and didn't get to go. He was on SeaLab II.

Every day, we had something assigned to us, but we had a lot of leisure time, too, and we'd go outside and hold our breaths. The three of us were training tank instructors, capable of diving to pretty good depths, like 120 or 130 feet of water, and hold our breaths. We were pretty good. Bond was interested in that, you know. Hyperventilate. How long could we go outside and hold our breaths? He'd keep a record of it. He did that during Genesis, SeaLab II and a portion of SeaLab III.

INTERVIEWER: I think we mentioned you and one other person on SeaLab I, but we didn't mention your other two colleagues. Who were they?

MR. BARTH: One was a doctor by the name of Bob Thompson. He was a submarine medical officer who didn't have a great deal of experience in diving. He'd been trained as a diver, was available at the time and had good credentials, so he was a bottom subject. The other guy was Lester Anderson, who was a staff member at the EDU when we did one of the Genesis runs. He

was a good fellow, good friend and a good worker and was interested in what he had to do.

Bond pulled him in to do SeaLab I. None of the people were strangers to the sea.

INTERVIEWER: Were there any other people involved with helping to shape the program, other than those who were directly related to the medical or diving aspects?

MR. BARTH: Oh, sure. There were a lot of guys off in the shadows. You know, all we did was sit in chambers, and those guys were constantly standing watch topside, 24 hours a day, and the guys for whom we gave blood, and those for whom we looked at the Rorschach ink blots. The Submarine Medical Center had a lot of doctors there. Every one of them had something that he wanted to try to do. There were a lot of people, a lot of guys working a whole lot harder than we were.

INTERVIEWER: Did Dr. Bond feel that SeaLab I was a success, based on the goals he had set for himself?

MR. BARTH: I'm sure he did. What did we do that wasn't successful? In everything we did, we proved that we could do it and believe me, there were a lot of skeptics during the very beginning who didn't think we would. We never hurt anybody. We were capable of doing just about anything we wanted to do. It was quite successful.

INTERVIEWER: Who were some of the most difficult skeptics to convince?

MR. BARTH: I still have to work with some of those guys. No, I don't. They're all retired. I'm the only one still working from those days. It was the Navy, in general. I think that you've been around the Navy long enough to understand that when you have something new and different like that, not everybody is going to jump up and wish you a 'fare thee well' and shake your hand and say, "Good luck." They're going to say, "Hey, you shouldn't be doing that." I had a lot of that from friends I knew. They would say, "You don't want to get involved in anything."

When you work at something long enough, you understand what it is you're doing, and the fear doesn't even enter into the picture. But there are always people out there that you have to convince. They don't want to jeopardize their Navy careers by killing a guy or two, whatever the

case may be. That's always a factor. You have to convince them. That was why it took so long to convince them that we could go from laboratory animals to goats, from goats to people, and then put people in the water, in the chamber, with no pressure. We had to convince them to let us put people in the chamber at a hundred feet. We had to convince them to put people in the chamber at 200 feet and then, in the water in a habitat. It took some doing.

INTERVIEWER: When SeaLab I concluded, did you have to go back to your boat?

MR. BARTH: Yes.

INTERVIEWER: You went back to being a quartermaster?

MR. BARTH: I went back to being a quartermaster. The captain said, "Where the heck have you been?"

INTERVIEWER: When you told him, what was his reaction?

MR. BARTH: He didn't understand it. He wasn't interested in it. He was only concerned about the fact that his chief quartermaster wasn't riding the submarine. Where in the heck was the quartermaster? Then, an article came out. The *Saturday Evening Post* did a nice story on us. It had a lot of pictures and on the cover page was the SeaLab. After that, he relented.

INTERVIEWER: Did you get your picture in the magazine?

MR. BARTH: I have one at home in a frame.

INTERVIEWER: Was he impressed?

MR. BARTH: I don't know. I didn't stick around long enough. The ship was in a shipyard. The submarine was in a shipyard in Philadelphia and I went there and finished up my time. I then got a set of orders to go to Panama City permanently and that was the end of my submarine riding days. I did about ten years, I guess.

INTERVIEWER: We're at roughly what, 1963?

MR. BARTH: No. We're up to January of 1965. Everyone who had been on the SeaLab program, including those of us who had been in Genesis, were brought to Panama City as part of the Man in the Sea Program.

INTERVIEWER: Tell me about the Man in the Sea Program.

MR. BARTH: Well, it was, by that time, proven that we could put men under pressure, breathing helium at depths. We had actually had four of them at 200 feet on SeaLab I, so Dr. Bond had drive. He would answer all the questions and go from first base to second base and prove it to everybody on second base that he could go to third base and then go on home. He had a program to get it done and he brought us all in from where we were, and I was on that particular submarine in Philadelphia. All the other guys were on different ships. Some were over here and some were over there. We all went to Panama City. Some of them went to the EDU at the gun factory in Washington and continued doing some other work, such as tests and so on. The rest of us went to Panama City, and we brought in something like 20 or 24 more guys and trained them for different aspects of what we were planning to do on Sealab II, which started in August of 1965.

INTERVIEWER: What were the facilities in Panama City like? What was there?

MR. BARTH: There was a small little Navy base. It's still there today. That's where I work now. That's where the EDU is. That's where the Navy Diving School is. It's a little base. It's a laboratory, really. It has a lot of scientists and a lot of guys who think they're scientists. But they're involved with a lot of things that take place underwater. The diving community is well represented in Panama City, but it was smaller then. Thirty-five years ago, it was a lot smaller. The base is constantly growing, but it's a neat little base. There are some good people there. Of course, it's right on the bay. The bay is right near the ocean. It empties into the ocean. It's a good place to dive and probably the only base that has that much activity involved in the ocean. They wanted the SeaLab program there. They built SeaLab I there. They built SeaLab I for us in Panama City.

INTERVIEWER: You said 'they' built Sealab I. Who were 'they'?

MR. BARTH: They were people at the base.

INTERVIEWER: Okay. They fabricated the base?

MR. BARTH: Yes. I was in the area because I was visiting my folks. That was in December of 1963, before Sealab I. My parents lived in a town not too far from there. I was home visiting with them and he asked me to come to Panama City. The people in the diving business at the base said, "Hey, we think we can help you with this project."

They had, in their scrap yard, a couple of those great big, old, long, steel HY80 tubes that were roughly ten feet in diameter and about thirty-some-odd feet long. They brought us down there, showed them to us and asked, "Do you think we could make a house out of these?" None of us were underwater habitat experts, so we thought, "You know, why not?"

INTERVIEWER: Where would those HY80 tubes have come from to begin with?

MR. BARTH: Many years ago, there was a program at the Navy base in Panama City that was called a 'mine defense laboratory.' They did a lot of stuff with mines. Those two big things, 'floats' we called them, were involved many years prior to that time, and they used them for some test program. They were used but HY80 is good steel. They were used and put out in there. But they were like cigars. They were rounded at one end and pointed at the other. We took both of them and cut the pointed end off of one, the rounded end off the other, and put both ends with the round end. We cut a hole in the bottom of it and did all the things that were necessary. We put six bunks in it, along with all the things that we needed, like a toilet and a shower. That habitat is still there, as a matter of fact, in the museum.

INTERVIEWER: What, then, was the next step from SeaLab I? What was taking shape there?

MR. BARTH: We gathered in Panama City in January of 1965 and started training for SeaLab II, which was going to take place that summer and did take place that summer.

INTERVIEWER: What sort of training did you do?

MR. BARTH: We had new guys who were not all Navy divers. We had some civilian oceanographers, but they were diver-qualified. We had a couple of other guys who worked at the base, as a matter of fact. We had other sailors who were divers, but not trained in saturation. But there weren't a heck of a lot of us who were trained in saturation. We embarked on programs. We

asked, "What are you going to do on the bottom?" They said, "This guy is going to do this. That guy is going to do that."

There were three teams. Each team had ten men in it, for a total of 28 altogether, because two guys stayed thirty days. They trained to do that stuff when they got on the bottom, but we had them dive in some different equipment that we were going to use on the bottom. We had them dive using other hand-held apparatuses that we wanted them to use on the bottom.

INTERVIEWER: Were they tools of some sort?

MR. BARTH: They were tools, like hand-held sonar devices. They were things like that. We had a wealth of different things.

INTERVIEWER: They weren't active sonar devices, were they?

MR. BARTH: Yes.

INTERVIEWER: Really?

MR. BARTH: Ping. Sure. I forgot the device's name, but, yes. It's probably still around, but I'm sure they have a better one now. It has been around for many years. You could hold it in your hand. It had earphones. You could ping and get a response back from a coffee can if you wanted to. We had a lot of that to do, and we were in Panama City doing all that training from January until around June. Then, we all met out in California and met the new habitat and went from there.

INTERVIEWER: Although the parts were discovered at the base, where was the habitat actually fabricated?

MR. BARTH: SeaLab I was fabricated at the base. SeaLab II was made from scratch at the naval shipyard at Hunter's Point, California, near San Francisco. It was a different habitat altogether. It was bigger.

INTERVIEWER: Was it a lot bigger? What else about it was different?

MR. BARTH: Well, it had a lot more stuff inside. While we were doing all that, we were also learning to make it work better. We built a bigger habitat. We had electric heaters in the floor to

keep it warm. We had a better system for scrubbing the carbon dioxide, for heating the place, for everything. It was a little bit fancier.

INTERVIEWER: The cold was a big problem, wasn't it?

MR. BARTH: It always was.

INTERVIEWER: We were talking about the fabrication of the habitat for Sealab II at Hunter's Point. Were the divers, or the aquanauts, themselves involved, the people who had to work the habitat? Were they at all involved in any changes that were made to the second-generation habitat?

MR. BARTH: Yes. They were a good deal involved. They were involved in the human engineering side of it, like 'where to put this,' 'put it here as opposed to putting it over there,' 'where do you think we can put this,' 'we can put something here or there,' 'where do you want it,' and that type of thing.

Scott Carpenter, who is a smart man, was involved in some of it. Scott was due to be the team leader of the first and second teams of SeaLab II and in fact, was. A lot of us were up there. The engineers or the builders of the habitat, not necessarily the engineers, but the builders, would rely on us to help with the ideas. We did that extensively on SeaLab I. By that time, we had some people who had SeaLab I behind them, so they knew a little bit more about where we wanted things. Obviously, when they were designing something, they had to design it so that it was safe and so that it worked better one way, as opposed to another. As far as where something was to be placed, they'd put it where we wanted it, if it were at all possible. That applied on SeaLab III, too.

INTERVIEWER: Where was SeaLab II positioned, physically, in terms of geography?

MR. BARTH: It was taken down to Long Beach Shipyard. We put it on a barge. It was taken down to the shipyard at Long Beach and the final outfitting took place there. Accumulating all of the stuff that we needed was done there. There were some parts still missing and so forth.

From there, we picked it up, put it in the water and towed it down to the Scripps Pier. We had a support ship anchored, an old barge that had been used during the Polaris days, and it was our topside support ship. It was a mile off the inner Scripps Pier, if that, and we put it on the bottom and made sure it was working. Then, on August 28th, which happens to be my birthday, the first team of divers went down. That's the reason I remember the date.

Now, today, when you do a deep dive, you can't swim down. You have to be transferred under pressure and you make your descent into the pressure zone by means of a chamber and a bell, and you ride the bell down. On SeaLab I and SeaLab II, the teams left the surface, swam down and got into it. Of course, when they came up, they had to get into the bell, surface and decompress from the bell into a chamber. They all went down, two at a time, got in it and stayed for 15 days. The second team went down and relieved them. The third team went down and relieved the second.

INTERVIEWER: How deep was it?

MR. BARTH: It was 205 feet deep.

INTERVIEWER: Were you a member of one of the teams?

MR. BARTH: Yes. I was on the second team.

INTERVIEWER: Who were some of the others who participated in SeaLab II, as divers?

MR. BARTH: I happened to be the only one.

INTERVIEWER: The only one? Was Carpenter involved in SeaLab II?

MR. BARTH: Yes. He was the team leader for II.

INTERVIEWER: Does that mean he stayed down for thirty days?

MR. BARTH: Yes.

INTERVIEWER: Was it consecutive? Did he come up and then go back?

MR. BARTH: No. We had one doctor go down on the first team and he stayed 15 days. He came up after that 15-day period and went back down for the third team. He did a total of thirty days, but had 15 days off in the middle. Scott was the only guy to do a full thirty days.

INTERVIEWER: First of all, tell me about the physical aspects of it. When you went into the SeaLab II structure, how was it different from the first one? You gave us a good view of what it was like to be inside the first when you looked around. Put yourself in the same situation. You're inside the second now, looking around. Contrast the two structures.

MR. BARTH: Well, I'm not seeing much because it's dark outside. There's no light from the surface. It's cold, as opposed to the bottom on SeaLab I, because we had coral heads and clear, warm water. On SeaLab I, we had darkness. There was some visibility, but with a light. We have beautiful portholes. We have great, big portholes in SeaLab II. You just can't see a doggoned thing outside.

INTERVIEWER: Did that make a difference in how it felt to live in a habitat for 15 days, seeing as you were the only one who had the common experience between the two?

MR. BARTH: Yes. It was the difference of a bright, sunny, warm day in the hypothetical camper. We were in a pretty zone, in a nice, warm place. There were pretty trees, good visibility, and mountains.

In the case of SeaLab I, there were a lot of critters out there, including some nice fish. We were in tropical waters, as opposed to the chilly Pacific off of California. SeaLab II was dark, dingy and very cold, and we saw little of the tropical fish. We had fish down there on SeaLab I. We always had light coming through the porthole, and we had minute shrimp, or perhaps plankton, that stuck on there all the time. The shrimp would come and eat the plankton or whatever small critters those minute shrimp ate. The fish would come and eat them and then, a bigger fish would come and eat those fish. We always had that going on.

INTERVIEWER: The whole food chain was right outside your window.

MR. BARTH: It was the big guy eating the little guy and it was to the tune of sea lions coming by and eating all of the big fish. You couldn't see anything on SeaLab II. Visibility outside the thing was so bad that if one of the guys were outside, he'd have to come to the porthole and make a face at you or something before you could see him.

Going outside wasn't a lot of fun because you were cold. The water temperature was cold. I don't remember what temperature we had, but in SeaLab I, we could sometimes go outside, in a set of trunks and nothing else on but facemasks. We were always told to go back inside and to cut it out, but we were just horsing around. We would go out naked. We couldn't do that on SeaLab II. It was cold, dingy, and dark. It was not a fun dive.

INTERVIEWER: It was cold inside, also. Was there any heating inside?

MR. BARTH: Oh, yes. It was okay inside. We had good heat. We also had something in SeaLab II that we didn't have on SeaLab I. It was a big tub that we kept full of hot water, and there was nothing better than getting in it after coming in out of the cold, and you were cold to the bone. Jumping in that warm tub was even better than making love to a pretty girl.

INTERVIEWER: Was the choice of a dramatically different environment deliberate? Did they want a cold, dark, more northerly climate, as opposed to Bermuda? Why not go back to Bermuda?

MR. BARTH: Well, they wanted a change. Divers did not generally get to work in the water in Bermuda, unless we were diving in the Bahamas or got to go to pretty places. Generally, it was in the middle of the winter, in a lake that a airplane was going to crash in. You chipped the ice and went down and recovered bodies or it was though you were recovering a drowning or something. They thought, "Why don't we make it realistic?" We were also looking for somebody who could support us. We went around the country like a bunch of gypsies and had to look for somebody who had a pier and electricity, and was willing to take all us mavericks in and support us. They had to give us the facilities on the beach, in the case of Scripps, to do it. All those things came into play. I was never involved in what went on in the offices in Washington. I was just one of the grunts in the water.

INTERVIEWER: As far as the people program was concerned, how did SeaLab II differ from SeaLab I? You described the various tasks. You described the kind of things Dr. Bond wanted

you to do. Are we talking about the same stuff, only more of it, or are we talking about different tasks?

MR. BARTH: It was both, probably. There was more of the same as far as the area of research and physiological stuff. We were still sending them bottles of bodily fluids and blood and so forth.

We had a dexterity coordinator outside, one of those things you had to crank one way and crank another the other to get the thing to travel in the right direction. It was like one of those mazes that they had you go through, and all kinds of stuff like that. We had equipment that we were testing.

We had three teams. Each team was geared toward a specific thing. They may have been the salvage people and their job was to salvage an airplane, foam it, and let it go to the surface. We had an airplane laying out there. They had to go out there and foam the airplane. We had oceanographers, three of them.

INTERVIEWER: Do you remember who they were, by any chance?

MR. BARTH: Yes. They were Bill Polbert, George Dowling and Wally Jenkins. We had Berry Cannon on, as well. All four of those guys, including Berry Cannon, came from the base in Panama City. I was on the bottom with three of the oceanographers on team two on SeaLab II, and they had different things that they wanted to do, but we would help.

INTERVIEWER: Were any of the Scripps people involved with it?

MR. BARTH: Yes.

INTERVIEWER: You said they were playing host?

MR. BARTH: Yes. There were three people from Scripps who were involved in it, I think.

INTERVIEWER: Do you remember any of the names?

MR. BARTH: Yes. One was Art Fleshig. I call him Art 'Flyspeck,' but the other two I don't remember. That was 36 years ago. Come on. Give me a break.

INTERVIEWER: I understand.

MR. BARTH: I can't remember my kids from thirty years ago.

INTERVIEWER: You're doing really well. Well, you said, 'different tests.' For example, there were three teams. You described a salvage team and an oceanography team.

MR. BARTH: Well, some teams had multiple programs. They weren't all salvage. One had salvage as opposed to the other two, which didn't. There was always something that we had to do. We had a weather station. I was the one who maintained the weather station on my team. I'd go out and up the line. We had this thing hovering off the bottom roughly thirty or forty feet. We'd go out and work on that.

We worked with porpoise from Point Mugu. We had a porpoise called 'Tuffy' that came down to us, and one of the guys in my team was someone I had actually been at the training tank with in New London. His job was working with a porpoise and a sea lion, both of which were trained animals. I'd go out and work with him, Ken Conga, a friend of mine who's long since gone now. But he worked with those porpoises. You and I are divers and we get lost. Porpoises are sent from the surface.

We had a noisemaker, too. He found us and we hooked a line back to him. He swam, guided or led us back to some particular place. There was a lot of that went on. We were trying to work and we developed a heated electric suit to warm divers. I had one. Some of the other guys had them. They were battery-operated suits. We'd go out and make dives and try to evaluate those suits. We had different pieces of equipment. We were on the edge of a canyon. We skirted down into the 350, 360-foot range down this canyon. We used different apparatuses to do all these different things.

INTERVIEWER: You had to tote your own lights?

MR. BARTH: Yes. I'd have to think some on that. We had a lot to do. We got up early in the morning, had a bite to eat and talked about what we were going to do that day. The team leader would go over everything, and each team had their work laid out. Once it was their time to go

outside, they'd go outside and do their thing. They went out for an hour or two, more or less, and come back. The next team then went out, or we might have had two teams out there.

INTERVIEWER: I'm not sure it was on SeaLab I or SeaLab II, but could you say anything about the cottage cheese caper? What was that all about, if you remember?

MR. BARTH: Cottage cheese?

INTERVIEWER: Yes. Someone decided they needed to have cottage cheese and had it delivered?

MR. BARTH: I don't recall that happening on my team, but I wasn't sitting there watching everything going on. When the other guys were down, I was off doing something else, standing watch or something, or I was just at home, taking it easy. That could have happened. If they had a particular request, we'd try to get it for them. As a matter of fact, I went to the store several times and got things that they wanted.

The porpoise trainer, Kenny Conga, was a Coca-Cola freak. He was, I think, addicted to the stuff. We didn't have any Coke on the bottom, for some reason or another, and the doggoned porpoise would come down and there was a harness that the porpoise wore for different things. Just about every time the porpoise came down, the people topside had a bottle of Coke tied to this harness. Kenny would take it. He'd grab it and run into a corner somewhere, like a caveman with a side of beef, and drink his Coke, daring anybody to come try and take it away from him. It was selfish.

INTERVIEWER: While you were doing this sort of thing, the manned space program was going on at the same time. Of course, Carpenter was a by-product of that program. Did you feel that in terms of visibility, assistance, and furthering the program, the visibility of the space program helped or hindered what you were doing, or did it matter at all?

MR. BARTH: I don't know that it mattered. We were certainly envious of their ability to garner the attention. Nobody is more of a space freak than I am. I think it's the neatest thing going. I think that NASA has done fantastic things with what they've had. Of course, they've had good

money to do it, but that's what things cost. But they've put men on the moon and done all those things. Granted, they lost people, but never in space. I'm fascinated. Of course, my friendship with Scott and the ability to ask him questions all these many years has added to that, but I wish that we, in this country, had just a fraction of the knowledge about the ocean as they have about space in the space program. I'd sure like to have just the money that it takes for one shuttle shot for our underwater programs. But I don't deny them. I don't have a bit of animosity toward those guys. I think the space program is the best-run organization in the United States of America. God, I just wish that we had been that lucky, to do the things they did. They've always had a neat group of guys to get done what they've been able to.

INTERVIEWER: What do you think SeaLab II accomplished, to further the process along, or to move it along?

MR. BARTH: You'd probably have to ask that of somebody like Walt Mazzone, whom you talked to this morning. There were a lot of things that we knew that we were capable of. If you are a company and come up with some new, unique product, and you and I are the guys that made it, we are comfortable with it. We know it's going to be received well in the world. It's a well-needed piece of equipment. This thing that you and I made gives us the capabilities to do things we never could, but we have to prove to the rest of the world that it does, in fact, do those things. We have to sell it.

NASA, for example, has, gosh, sales promotion people for the space program and they are great guys. They're unique. We never had that capability. I would like to be able to say that in SeaLab II, we answered a lot of our own questions. We proved that we could get the job done. As a matter of fact, all the skeptics, who were obvious to us and existed, never showed up after SeaLab II was over. It was successful. We put 28 or thirty-some odd people in the depths and left them down there for two weeks and never hurt anybody. One guy got the bends. Then, all of these guys started coming out of the woodwork, you know. The Navy decided, "Yes. Those guys

know what they're doing." That was what we did on SeaLab II. We proved to them that we could do what we said we were going to do.

INTERVIEWER: When SeaLab II was finished, to where did you have to go back? Was it Panama City?

MR. BARTH: I was living in Panama City. We went back to Panama City and knew that Dr. Bond was going to try for SeaLab III. We went back to Panama City in November of 1965 and the ball started rolling.

The next year, we all met outside of the city. We left Panama City and went to San Diego and set up housekeeping there. We started bringing in newer people and training them for SeaLab III. SeaLab III was made from the SeaLab II habitat by refurbishing or redesigning it, whatever you want to call it.

INTERVIEWER: Whatever else was done to the habitat, besides the effort to constantly make it level and improve the attitude of the structure?

MR. BARTH: We added a room on each end. It gave us more room. We did different internal things like you would do on a car. You know, the 1980 version looks the same as the 1981 version, but there are new and improved things inside. The cigarette lighter works better. The bunks were better. The refrigerator was better. The cooker was better and so forth. The biggest thing was that we had to set SeaLab II on the bottom. Unless we had a level ball field out there, whatever the angle was of that field that we set it in, the habitat was going to be that way. We changed that aspect. The habitat was buoyant and hung off a clump that we put on the bottom. It hovered, so to speak, not floating around, but it hovered. Then, we clamped it. We put legs on it. The legs were kind of my idea. By that time, I was the habitat officer and was therefore responsible for some of the things we did, like outside storage, for example.

INTERVIEWER: By 1965, what rank were you?

MR. BARTH: I was chief quartermaster. I made warrant the next year, I guess it was.

INTERVIEWER: When you moved to San Diego, you became part of a larger organization, didn't you?

MR. BARTH: Yes. It was much larger.

INTERVIEWER: It was the submergence program. What effect did that have on your ability to operate the formulation of goals and the nature of the project, as opposed to the two that came before, from the point of view of the diver, of the swimmer participant?

MR. BARTH: We had a lot more people. We went from a small 'ma and pa' organization to a large corporation with a board of directors and so forth. We had a heck of a lot of boards of directors.

INTERVIEWER: Everybody wanted to run the show?

MR. BARTH: That's all I want to say about that. When you made one step, you were sure that you could make the second step. When you made the second step, you were pretty sure you could make the third step, and you made it. Pretty soon, you could eliminate the next four or five steps because you went from one to three. You could go from four to six without a problem and so on. You learned that you were capable of more and you did more and then, you went on to the next step. That was what we did constantly. We showed that we could do that. We answered our own questions. We generated the things we wanted to do, found out ourselves and at the same time, we generated answers to those people who didn't think we could do it.

We had new managers on SeaLab III that we didn't have previously. We had to recognize other people that were part of the management staff of the Man in the Sea Program. Obviously, we didn't always agree with things they said. By that time, it was in the late sixties. We had almost ten years of experience doing it ourselves and never having to worry about doing it right or wrong and so on. All of a sudden, we had people who made sure that we did it safely. It grew from a ma and pa outfit to a large corporation. That is what it boils down to.

INTERVIEWER: Was that good or bad?

MR. BARTH: It depended on where you sat. I didn't like it.

INTERVIEWER: Why?

MR. BARTH: I didn't like the idea that there were a lot of people who didn't know my job telling me how I should do it. I mean, that's Bob Barth. I have been known to be a little outspoken and opinionated, but I don't believe anybody should direct me as to how to do my job when I've done it for a long time and they just got here. I blame some of the problems that we had on things that that we shouldn't have had to go through, but again, that is my opinion.

INTERVIEWER: Did you start thinking that perhaps it was a place in which you shouldn't have been? Did you think that you should have been elsewhere?

MR. BARTH: Oh, no. No, I did not. I was selected as the team leader for the first team on SeaLab III. I had eight guys with me. We trained to do our particular jobs. We had five teams on SeaLab III and each team had a lot to do. My team was to get in, open it up and then, we had projects that we did outside. The second and third teams both had different things to do. I was selected as the team leader for the first team. Man, we hadn't gone to 600 feet before and we were going to go down and live at 600 feet. We were quite confident that we were going to be okay. It didn't work out that way, but it was a good opportunity. Not once in my life did I ever think that I wanted to be elsewhere. Lord, no.

INTERVIEWER: Did it not work out because 600 feet was too far?

MR. BARTH: That had nothing to do with it. Maybe it was just a question of some people who weren't trained enough, a problem with equipment not functioning as it should have or different things that went wrong that shouldn't have gone wrong. There was a redesign of something that worked fine in the first place.

INTERVIEWER: What was that?

MR. BARTH: It was the redesign of the penetrators that fed the electrical and other stuff into the habitat. They changed that on us and that was where we had our leak problem. There were a lot of boards of directors.

INTERVIEWER: What were some of the other problems that you were running into? You all were, as I understand it, getting a little agitated over the fact that things were not working the way they were supposed to. There were helium leaks. There were all kinds of things. What other things can you remember that were really aggravating to you?

MR. BARTH: Well, you're talking about a problem. The habitat, for example, was going to be on the bottom and it was going to house forty people or better. Each one of those forty people, or at least two, out of that forty, in each group, had a project.

Plus, everything was new. We had new people who wanted to put a stamp of approval on something. We had new systems in effect in the Navy that we didn't have before, regarding decision-making and the certification-type people and so forth. We were constantly being told, "You can't do this that way. You have to do it this way," as opposed to another way, or, "Here's the way we're going to change it. Instead of doing it the way you thought, we're going to do it this way." We had equipment that didn't make it there on time and we had to find a different way to do it. I think you find that in any organization that grows as rapidly as we did.

I saw things that annoyed me, and other guys saw things that might have been just the way they had to be. Heck, none of us like change. We were confident that we could do it, having done it before. You know, in my case, I was maybe so confident that I should have been more aware that all those things were going on. But I had done two SeaLabs and had been involved in all of the tests before that with the Genesis programs. I was kind of a smart aleck. I didn't need to be told by some Johnny-Come-Lately what it was. It didn't create a problem with me doing my job or him doing his. I just didn't always agree with the changes. Equipment was placed in there or reshuffled and I didn't think, or other guys didn't think, that it should have been. Those were natural things you ran into. Gosh, anybody is going to have that problem, but that's the way it is.

INTERVIEWER: As the manned space program has had casualties, SeaLab III had one, also. With the kind of swift and substantial changes, differing opinions and points of view that you described, do you think such things contributed to the loss of your colleague?

MR. BARTH: I don't know. Are you talking about opinions that should have been coming from people who were making those decisions, topside? I was never one of those people. My job was to look after the habitat and the people. I chose Berry Cannon. Berry was an electrical engineer who had been on the bottom on team I on SeaLab II. He was a good man in the water. He was a good worker. There was nothing about Berry Cannon that was in the negative column at all. I wanted him on my team and he was needed on my team. If there was a problem with the habitat, Berry knew how to fix it. I was lucky enough to be able to select the majority of the people who were on my team, and those were careful considerations to make. A thing that you broached was personality. You can get a person who might be the smartest guy in the world but has a personality like a dead cat and doesn't contribute to the rest of the team, someone who is not a team player. That guy annoys everybody. He doesn't pick up his share of the work. He's lazy. Those are the kind of guys you don't want. Of course, we didn't have them. We had good people, all around.

You can imagine ten guys, working for two weeks on the bottom of the ocean, and I mean *working*. You could get one nerd in there who didn't carry his load. He didn't need to be there. I was able to pick the cream of the crop for SeaLab III, team I, and I had good people. Berry was the unfortunate victim of a little bit of chaos and equipment malfunctioning and so forth, and he paid for it. I knew probably Berry Cannon pretty well, and I know darned well that Berry would have never said to quit because he was lost.

We always had that potential. We were diving and going to live in 600 feet of water. Obviously, if we kept going in that direction, we were going to have problems. We had new things, like deeper, newer equipment. The physiological attack on the human body is more pronounced as you get deeper, so your danger, if you want to call it that, is heightened. There was really nothing dangerous about saturation diving, but danger, if you want to use that word, increased as you get deeper. All of that was fully known by us. None of us were worried about it.

If you want to know the story about Berry's loss, I'll tell you. Team I had gone down. We had two PTCs. By that time, we had developed a chamber on the surface with a bell on top. We had two on the support ship. The way it was laid out was that I took half of team I in my bell, in my chamber, and we went to 600 feet. The rest of them got in the other chamber and went to 600 feet. I took four of us in the bell, including myself, and we went down to the ocean floor, 610 feet down. We went out and over to the habitat and worked on it. But we had some problems with the habitat, like getting into it, pressure versus this, and some other problems.

We didn't get into it on our first dive. Berry and I had on apparatuses, the diving equipment that was sent to us through the medical lock, transferred into the chamber and then given to us, and we took it to the bell. He and I each wore one when we went out and did our first dive. We didn't get in. We were extremely cold. We didn't have any heat, so the cold was getting to us. We came back, got in the bell and came back to the surface. We warmed up a little bit. Then, they took those two apparatuses out and fit in two new ones.

They had a habitat and were worried about it imploding on the bottom. It was leaking. They were trying to keep from losing it. Everybody was running around. Everything was accelerated. In the effort, somebody inadvertently grabbed an apparatus out of the rack that didn't have any CO<sub>2</sub> absorbent in it. The two of those were locked into us to replace the ones we had worn on the first dive. Berry grabbed the one that didn't have any CO<sub>2</sub> absorbent in it and I got the other one. You don't last too long at 600 feet without CO<sub>2</sub> absorbent on a semi-closed circuit apparatus. He was re-breathing his CO<sub>2</sub> because there was no absorbent. He got a high concentration of CO<sub>2</sub>. It only takes a few minutes for that to happen. By the time we got there and had been out for maybe four or five minutes, he went into convulsions, and that was it.

We were doing things that people had never done before. There was a chance of losing someone. You hoped that something like that wouldn't happen, but there was a chance. It should not have happened, but it did. That didn't mean, however, we should have scrubbed a beautiful program like that, which they did.

INTERVIEWER: Do you think that was indeed the reason they scrubbed it?

MR. BARTH: I don't know. You'd have to ask those guys who were sitting up topside. I was inside. I had a weeklong decompression. When I surfaced after that decompression, everybody was gone. That was the end of that, except those who decompressed us. They were there.

INTERVIEWER: What did you with the SeaLab III?

MR. BARTH: The Navy put it somewhere for a while and eventually cut it up.

INTERVIEWER: Where did you go?

MR. BARTH: I stayed a little over a year more and I then retired.

INTERVIEWER: When was that?

MR. BARTH: I retired on the first of May in 1970 and went back to Panama City to build what is now where the Experimental Diving Unit is. I was offered a civil service job, to come back and help build the ocean simulation facility, which is a very large, hyperbaric deep diving facility. I had a lot of background in saturation by that time. The same people who generated all the interest, generated EDUs there, got us involved in the SeaLab program, built SeaLab for us, engineered SeaLabs II and III for us, were the same people who wanted to build the ocean simulation facility where I am today. I got out and went to work there but only made it about two years. I just didn't like civil service life. I took off for 16 years on the oil patch and worked off there doing different things. I came back about 15 years ago.

INTERVIEWER: What was the oil patch?

MR. BARTH: It was offshore petroleum diving.

INTERVIEWER: Were you working for oil companies or salvage companies?

MR. BARTH: I worked for a French diving company and then started with another guy.

Another two guys started their own company in the Middle East in a city that you've never heard of called 'Dubai,' and we started a diving company there. We eventually expanded into the North Sea and Southeast Asia, out of Singapore. We worked Egypt, Iran, the North Sea and Indonesia.

INTERVIEWER: What sort of work would you do for the oil company?

MR. BARTH: I was diving.

INTERVIEWER: What were you trying to accomplish?

MR. BARTH: Well, the majority of the oil in the world today comes from the ocean. You don't just run down and stick a hose in the ground. You have to do a lot of things. You have to put structures in. You have to drill. When you get X number of wells in some particular field, you might have a field that has upward of thirty or forty wells in it. You have to connect them all with a pipeline. You have to feed them into a place that takes the petroleum and does something with it. It's underwater construction.

There are different phases of the operation. There's exploration, the seismic work to find that there's petroleum there. There's the drilling. You might find, from your seismic work, the field has to be laid out with forty wells in a forty square mile area, or whatever it may be, and they design all that. Their diving companies do the underwater phase of it for them.

INTERVIEWER: You have no regrets about SeaLab?

MR. BARTH: My life?

INTERVIEWER: Yes.

MR. BARTH: No, I have not a one. There has been the pretty girl here and there with whom I screwed up, but other than that, no.

INTERVIEWER: Is there anything that you thought I would ask but didn't?

MR. BARTH: No. I had no idea what you were going to ask. I didn't figure it would be all this easy.

INTERVIEWER: There you go. Thank you for your time. I really appreciate it.

MR. BARTH: Okay.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

ORAL HISTORY OF THE MAJOR PARTICIPANTS  
IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS  
INTERVIEW OF  
DR. ROBERT BORNMANN

Kensington, Maryland  
Tuesday, July 22, 2003

## PROCEEDINGS

INTERVIEWER: Would you tell us something about your early childhood, and start with when and where you were born, and where you went to school?

DR. BORNMANN: I was born in Pittsburgh, Pennsylvania. But before I was five, my family moved to Charleston, West Virginia. I went to elementary and secondary schools in Charleston, West Virginia, graduating from Stonewall Jackson High School, a school that no longer exists. I graduated in 1948. I then went to Harvard and graduated in 1952. I went to the University of Pennsylvania Medical School and graduated in 1956. I interned at Ford Hospital and then spent two years on active duty in the Naval Reserve with the Navy Antarctic expedition, Deep Freeze 3, where I was the naval officer in charge of the Cape Hallett IGY station.

I applied for a Navy residency in internal medicine, but there was no mail delivery. They said, "Fill out a supplemental form." which I never received until after the rolls were closed for the following year. So, I went back to Ford Hospital for a first-year of residency in internal medicine, which would now be a second year (after the internship).

In the middle of that year, I decided that I had really enjoyed the Navy. I came back on active duty with a regular commission. When I went to the Navy's Bureau of Medicine and Surgery (BUMED) with the intention of applying for residency training, it was again too late in the year. They asked if I would mind going to submarine school, and spending a couple of years in the submarine force, while they looked for a place for me in the medicine residency program of a Navy hospital at the level appropriate to my already-completed training. I said sure. Captain Gerald Duffner was the Director of

Submarine Medicine at the time. Again, it was so much fun that I never went back into the hospital program. When I graduated from submarine school, Captain Duffner asked me to go to the underwater swimmers school in Key West and I was there for ten months. Then he asked me if I'd like to spend the summer with Ed Link in the Mediterranean, and I did.

When I returned from that in early October of 1962, I spent 12 months in a fellowship with Professor Chris Lambertsen at the University of Pennsylvania. From that, I was sent to the Navy Yard to be the assistant medical officer at the Naval School Deep-Sea Divers, as it was then called. Bob Workman was the head of the Medical Department of both the Experimental Diving Unit (EDU) and the diving school. My submarine school classmate, Mickey Goodman, was the assistant medical officer.

INTERVIEWER: From what you said, it sounds as though maybe Duffner was the person who got you into the diving field. Is that correct? Was it Captain Duffner, or was it someone else who influenced you to become an undersea medical officer?

DR. BORNMANN: Well, it was Joe Rossi.

INTERVIEWER: Tell us something about Joe Rossi.

DR. BORNMANN: Joseph J. Rossi was a very, very interesting guy. He was a trained pediatrician. He was a commander, I guess, at the time. He was the assistant in the BUMED personnel branch. I went in to see him, and he said, "Well, what can we do with you?" When Duffner came in, Joe asked, "How many people do you need for the next class of submarine school?" "How many you got?" "Would you accept Bob Bornmann?" He said, "If he's interested." I said, "I have 20/200 vision. Is that a problem? It is for flight surgeon, the aviation medicine training at Pensacola." He said,

“No, it's no problem for you.”

So I went to submarine school training which included the medical officer's course at the diving school. Then, Duffner called me up and said, “Nobody volunteered to go to Key West. I really need someone that I have confidence in to go down there, because we had a small problem with the medical department there. Would you accept?” I said, “Captain, I'll go wherever you send me. I'd love to go, just send me.”

INTERVIEWER: Of the people you have encountered in your diving career, whom would you say you admire the most, and why? How did that person influence your career decisions?

DR. BORNMANN: Well, that's a very difficult question to answer, because I have been associated with, or worked for, a series of extremely interesting, talented, and accomplished individuals, starting with Joe Rossi. Incidentally, Joe Rossi resigned his commission to become a Trappist monk. After he'd been there eight weeks, the Prior called him in and said, "Joe, a Trappist monastery is not the place for a fat Italian who likes to talk as much as you do."

Then, I met Captain Duffner. I met Ken Ploof and Dave Schaible at the underwater swimmers school. I met Lambertsen. I was the assistant to Bob Workman at the experimental diving unit. When I was transferred from that, I became the assistant to George Bond in the SeaLab Program at the Deep Submergence Systems Project office. I also worked for Jack Tomsy.

When I left there, I went to England as an exchange medical officer. I worked for an astonishing group of individuals, eight of whom made flag officer, and three made vice admiral and surgeon general of the Royal Navy. I won't go into a detail with their

names, because they're probably not of interest to the American Navy. But when I came back, I was on the staff of J. Edward Snyder, Jr., the Oceanographer of the Navy. Ross Williams relieved him as Oceanographer of the Navy. I worked with Brad Moody when he was just a captain, before he was promoted to Rear Admiral. The list just goes on, continuously. When I was in the Mediterranean, I spent four months with Ed Link, the inventor of the Link Trainer. He was the inventor and developer of many things for underwater work.

INTERVIEWER: It is clear that you have encountered a lot of extraordinary people. But did any of those people become a role model for you?

DR. BORNMANN: They all did.

INTERVIEWER: It was kind of eclectic?

DR. BORNMANN: Yes, it sure was.

INTERVIEWER: You got a little bit from each?

DR. BORNMANN: I got a little bit from each. Some of their qualities didn't fit in with my personality. But the ones that did, I glommed onto. As a matter of fact, when I worked for George Bond, I learned to copy his writing style. As you know, he was a superb writer. I improved my own writing by drafting things for him to send out as official correspondence.

INTERVIEWER: Who would you say, among those that you've encountered, had the most to do with, or influenced you most, in making career decisions? Are there two or three people that you would single out?

DR. BORNMANN: No. You're not going to get a response from me, Don, on that line. I'm sort of the guy that stumbled happily along in life, accepting what was given to me,

and was blessed by an extraordinary succession of gifts in that area. I don't know that I deserved it. I just sort of fell into it. I was grateful to the people I met. But I'm not a decisive person.

INTERVIEWER: As you went through your career, associated with diving and divers, you said you went to the underwater school. You went to the medical officers' course in diving and so forth. Of those schools that you had the opportunity to observe, was there a best school in any way? Was any one of those that you encountered the best school?

DR. BORNMANN: Well, the best school would be the one that most nearly reached the objectives for which it had been established. I would say that that's like asking Ford [motors?], "What is the best car you ever produced?" They will tell you, "the one we're manufacturing this year."

INTERVIEWER: It wasn't the Edsel, though.

DR. BORNMANN: If you had asked them that when they were producing the Edsel, they would have said yes. Now, I've got to tell you, when I was at the underwater swimmers school, it was at the height of its career. The skipper was Ken Ploof, and the training officer, later the executive officer, was Dave Schaible. We had outstanding instructors. We were taking on new tasks and doing them well.

Then, I got transferred up to the diving school, and the same thing was true. The Navy was going through a change in its approach to diving. We were given greater and greater tasks so as to be able to dive to deeper depths for longer periods of time. The diving school and its training, and the experimental diving unit and its R&D just reacted to the challenge in a superb fashion. I'm grateful to have been there to see it.

INTERVIEWER: The underwater swimming school no longer exists, correct?

DR. BORNMANN: Well, I think there is an underwater swimmers school, but it's not run by the Navy. I'll tell you more after our reunion next May, in San Diego.

INTERVIEWER: Can you talk about the underwater swimmers school, when you saw it at its height, as it evolved into its demise, if you will? Where did it go? How did it fraction?

DR. BORNMANN: The underwater swimmers school, as I understand it, was established to train EOD swimmers in diving, both second-class air diving and SCUBA diving. Having a capability to train divers, they were asked to train second-class divers for other purposes. The Atlantic Coast UDT asked if we would set up a program to train UDT swimmers to become SCUBA divers and that was done at Key West.

As it turned out, Dave Schaible, who was the executive officer at the underwater swimmers school, went up to Indianhead to become the commanding officer of the EOD school, which was a tri-service school. He succeeded Ken Ploof, who had also gone to be the skipper of the EOD school. Dave got money to build a facility with the capability to carry out the EOD diving training right there in Indianhead. Then, the Indianhead school was closed and moved down to an Air Force base, I believe. I can't remember its name, but it was somewhere near the Florida panhandle.

INTERVIEWER: It's Eglin Air Force Base in Florida near Pensacola.

DR. BORNMANN: There is a tri-service EOD school there. I don't know where they train their divers. But only Navy EOD are divers. The old separation of responsibility was the high-tide mark. If it was "wet" it was a Navy responsibility. If it was "dry" it was an Army responsibility. They say that the Army's creed is, in an indeterminate situation, 'Just piss on it and call in the Navy.'

INTERVIEWER: You were in diving at the time when saturation diving was in its infancy, and watched that through its application in the Navy to the time that now, we have only a few saturation divers in the Navy. Can you talk some about the early years, and bring it through how it impacted you and some of your involvement in seeing that saturation diving became an acceptable way to dive, I suppose is the way to ask the question?

DR. BORNMANN: Actually, saturation was essential, but not in the way in which its creators envisioned it. I don't want to get sucked into the debate about who was the creator of saturation diving. If you go by priority, Haldane mentioned it as a possibility, though he never did anything about it. In my mind, George Bond, a Navy Medical Corps officer, brought saturation diving into the Navy.

I was also associated with Ed Link in the Mediterranean in 1962 when he did the first at-sea operational helium-oxygen saturation dive. Ed's vision was to reduce the cost of diving by decreasing the amount of decompression for a given amount of work underwater. George's vision was of people living and working under the ocean. That last was how the three SeaLab projects were envisioned. It made it possible for the Navy to take on long, deep diving, because even if you made a thirty-minute dive to 750 feet, you might not have been saturated when you left 750 feet, but you certainly were saturated before you reached the surface again.

The big change was to make the divers' residence in a deck decompression chamber, rather than in a habitat on the ocean floor. Commercial diving companies all around the world adopted that process, procedure, and equipment. But we lost out in the race with the engineers who developed first the remotely operated vehicles (ROV), and

then the autonomous vehicles (AUV), and the armored diving suit. Deep human diving is [was] becoming more and more infrequent. As I understand it, the specific requirement for the Navy, for a human diver, is to be able to dive to 300 feet, which, curiously, is what we could do in 1957, when I came on active duty in the Navy.

INTERVIEWER: You spent a career in the Navy. You certainly spent most of it in diving and submarine related fields and positions. Did any of that affect your retired life? If so, how?

DR. BORNMANN: There was not a great call for submarine medical officers in the civilian medicine establishment. I was advised, five years before I retired, to get a diploma in another specialty. Because I'm basically a lazy guy, I figured the easiest thing to do was to get a certificate in occupational medicine, which accepted a lot of the experience and the education that I had had in the Navy as a submarine and diving medical officer. But I didn't work in that area. When I retired in 1985, I essentially went and put my feet up and enjoyed myself.

INTERVIEWER: Think back to your first underwater experience and tell us about it.

DR. BORNMANN: I couldn't even tell you what it was. You're referring to the training?

INTERVIEWER: Yes, or tell us about whatever your first underwater experience was.

DR. BORNMANN: Well, I am not a phobic person. But I have had three panic attacks that I can remember in my life. One of them was when I accidentally turned off my air during an examination, a job to complete on the bottom in the Anacostia River. I struggled for a minute, and then I said, "Well, I have enough air in the helmet. I'll just finish the job and go on up before I worry about it."

The second time was when I was in a Royal Navy submarine, and they turned the

ventilation off. They went silent. I was in a bunk bed in a British submarine and I couldn't find the zipper of my sleeping bag. I was in a cocoon, and it was getting hot. My heart rate went up. I finally got my fingers up to the top of the zipper, unzipped the sleeping bag, rolled over and went to sleep. I don't even remember when the fans came on again.

Then, the third time was on an airplane, when I was in the middle of a three-seat arrangement. The overhead baggage level seemed to be right above my forehead. The lady in front of me let her seat back. It was inches from my face. I said to the guy on the aisle, "Let me up." I got up and walked around. I calmed down.

INTERVIEWER: In your diving career, is there any single event that is most vivid in your memory?

DR. BORNMANN: No. I was not much of a working diver. I was a bureaucrat, an executive manager in my association with divers.

INTERVIEWER: Were you involved in any of the wartime diving experiences, such as Vietnam?

DR. BORNMANN: No.

INTERVIEWER: Did you have any life-threatening experiences in diving? Were there any?

DR. BORNMANN: Well, actually, people died in diving. But they always seemed to die before I arrived or after I left. At Key West, there was an individual who collapsed on a several-mile run and died of acute hemorrhagic pancreatitis. There was a guy who drowned at the diving school when Walt Bergman was a student. Paul Linaweaver was on the medical staff, and that was before I arrived. Then, at the EDU, there were two guys who were burnt in the EDU chamber fire when I was at the diving school.

INTERVIEWER: How about your own life? Did you ever encounter a life-threatening situation in diving?

DR. BORNMANN: Yes. My life was saved. I had a regulator failure. I couldn't breathe. I tried to surface, and I got hung up. My SCUBA bottles had got caught on something. The corpsman in the group saw me struggling. He reached down, grabbed me by the head, pushed me down, freed me and pulled me up, and saved my life. He told me, when I explained what had happened and how I got in the particular predicament, "Oh, I remember. I tried that regulator and it didn't work, so I used another one." When I arrived, it was the only one left.

Because of his failure to report it, he risked causing my drowning. Instead, he ended up saving my life. I later found out that this same corpsman had purchased for the sick bay the barbiturates that a medical officer used to commit suicide. After he left the Navy he taught his boss' wife how to shoot a pistol. She shot and killed her husband, his boss. You ought to interview him for an oral history.

INTERVIEWER: I don't think so.

DR. BORNMANN: He was a diving corpsman.

INTERVIEWER: What about the equipment that you used in diving? What kind of equipment were you qualified to dive with, so to speak?

DR. BORNMANN: In addition to the deep sea air and helium dress, I started out with the simple air SCUBA, a two-hose regulator. I was trained with the semi-closed circuit and the closed-circuit apparatuses, but never used it operationally.

Then, I was involved in the biomedical research to develop modern Navy diving equipment. The other thing was that in the 1970s, the Bureau of Ships or NAVSHIPS

had developed a new type of SCUBA for use by SEALs. Dave Schaible was a captain, a SEAL captain, out in San Diego. I had worked with Peter Bennett for several years at RNPL , when I was in England. Peter had gone to Duke University. I arranged with Peter to take half a dozen prototype diving rigs from the EDU. Dave Schaible sent SEAL personnel from the Navy to Duke, and we ran a program to familiarize the SEAL personnel with the proposed new equipment, to check the biomedical background in its use, and to develop new decompression schedules for the gear..

INTERVIEWER: In your diving career, is there anything that you experienced, and it could be more than one thing, that you would categorize as something you will never forget?

DR. BORNMANN: There were no epiphanies, if that's to what you're referring.

INTERVIEWER: Well, I think you may have already told us, but as a Navy medical officer, what factors motivated you to select submarine and diving medicine as a career specialty, or was it just opportunistic?

DR. BORNMANN: Well, I'd hate for you to think that I'm an opportunist. But it did happen by chance encounter, and by having a moment of not knowing what to do, and someone said, "Why don't you try this?" That was truly a critical pivot moment in my life. It turned out to be a greater thing than I'd ever imagined when I said, "Sure, why not?"

I've got to tell you, without being disparaging of the Navy medical department hierarchy, that during most of my career, I worked for line officers. That was repeatedly an outstanding experience. I have talked to other Navy doctors who worked in medical clinics and hospitals and they didn't have nearly the amount of fun that I did.

INTERVIEWER: Was that because of your association with the line in the Navy?

DR. BORNMANN: It was that and working on truly naval tasks and missions.

INTERVIEWER: In the field of diving and submarine medicine, as you practiced it, what did you encounter that you would say was the most intellectually stimulating?

DR. BORNMANN: I'd have to think about that answer.

INTERVIEWER: You can think about it, and we can come back to it.

DR. BORNMANN: Okay.

INTERVIEWER: You have mentioned several people who influenced you in your Navy career. Going to the line side, you mentioned Dave Schaible, for example. Is there anyone else on the line who really shines out as a person who really struck you as a role model, or someone who influenced as to what you did, or decisions you made? Are there any other line officers you can think of who interacted with you in your career?

DR. BORNMANN: Well, the first one that comes to mind is clearly Admiral J. Edward Snyder, Jr. Ed Link wasn't in the Navy but he was an authentic historical character in the United States. Being associated with him, and seeing how his mind worked, and then going back, and over the next ten to twenty years, finding out all the things he had done, and remembering little comments and stories he told were fascinating. You ought to get Charlie Aquadro to tell you about Ed Link, too, because Charlie spent more time with Ed than I did.

INTERVIEWER: Thinking back now, in your Navy career, and knowing where we are today, and I say 'we' to mean the Navy diving and submarine medicine fields, collectively, what would you say are areas that still require biomedical research, or are there no areas left? Are we simply re-plowing old ground, as one of the diving medical

officers said one time, after he became an admiral. I can't think of his name.

DR. BORNMANN: Walt Welham, Charlie Waite, Lou Seaton, Jim Zimble, Hugh Scott, and Jim Summitt all made admiral.

INTERVIEWER: It was Jim Summitt. He said that all we were doing in undersea research was re-plowing old ground.

DR. BORNMANN: He may have been talking about specific expenditures, not about the program as a whole. Would you say there are still areas to study?

DR. BORNMANN: Well, going back to his comment, I think one of the defects of American Navy labs is they don't do library studies before they start spending the available research funds. Then, they end up, as Dr. Summit said, re-plowing old ground.

INTERVIEWER: For the readers of this book, define 'library studies.'

DR. BORNMANN: Well, there was an initiative, for instance, to come up with a solution to cold weather and cold water exposure. One lab manager said, "I've got to get a hunk of those funds. Anything will do, as long as we can sell it in Bethesda." They ended up, as far as I could tell, never checking to see what the Royal Navy, the Norwegian Navy, the Canadian Navy, and the Canadian forces had ever done in this area. They just went ahead and said, "It sounds like a good idea. Let's find out if it works."

INTERVIEWER: Ocean floor habitat diving was moving along at a remarkable pace during the early part of the last half of the twentieth century, until we lost Berry Cannon during the operation of the Navy SeaLab III. From then onward, habitat diving lost its luster. What is your opinion as to why that happened? Was it Berry Cannon's unfortunate death, or was it something else? Also, if Berry Cannon had not died, what is your opinion as to what the Navy would have developed from the SeaLab experiments?

DR. BORNMANN: First of all, Berry Cannon was a wonderful individual human being. His death was tragic, and a great loss. But I think that the subsequent history of diving would not have been changed much if he had lived and if SeaLab III had successfully completed its planned program. All the Navy objectives in the SeaLab III program were attained later.

INTERVIEWER: The DSRV's, or Deep Submergence Rescue Vessels, are going out of service. They're being replaced by another type of submarine rescue system in the Navy. What is your opinion about the utility of the DSRV's during their lifetime, and what is your opinion about the new submarine rescue system, the Submarine Rescue and Diving Recompression System, if you are familiar with that new one?

DR. BORNMANN: Well, I'm not familiar with the new one. I can give you no evaluation. I was at DSSP when they designed and built the DSRV's. They functioned admirably well during their life program. As far as I know, they were never utilized since they were never called on. Are you asking me about the engineering quality of the vessel, or about the philosophy of submarine escape, rescue, and survival.

INTERVIEWER: Do you have an opinion on the statement that has been made about the DSRV's, that they were primarily for telling the public, in general, that if your sailor goes down in a submarine, we can go get him, and for no other real purpose?

DR. BORNMANN: Don, I don't understand the question. I don't think my comment would add anything to the debate.

INTERVIEWER: The reason I asked the question is because that has been said although I don't agree.

DR. BORNMANN: I know you don't but I don't have a high opinion of the question.

INTERVIEWER: We'll leave it alone. What is your opinion as to the equipment that was developed for submarine rescue, such as the one atmosphere diving unit, or diving suit, and the submarine escape and immersion equipment, the British submarine personnel escape system, and those kinds of things? What is your opinion of those pieces of gear?

DR. BORNMANN: I think they were marvelous accomplishments. Particularly the submarine rescue and escape equipment. The one atmosphere diving suit is being used commercially right now. Right?

INTERVIEWER: Yes.

DR. BORNMANN: You don't know what the situation will be in any future submarine loss or tragedy. We do the best we can to anticipate it, and to come up with something that might help, in a hypothetical future situation. But it's a struggle. It's a balance of objectives, resources, and trade-offs. It's about whether you need it, whether you can afford to put it aboard, and whether that energy and money could be better spent to avoid the accident that disables the submarine.

INTERVIEWER: In the field of diving and submarine medicine, what proved to be the one thing that brought you the most satisfaction? Is there any single thing?

DR. BORNMANN: No. I had 27 years, of which almost a quarter century was spent in undersea medicine, and working with submariners and divers. It just was a succession of wonderful collaborations, acquaintances, insights, and personal satisfactions.

INTERVIEWER: You surprised me with that response.

DR. BORNMANN: Why is that?

INTERVIEWER: I would have guessed, with a high level of probability, that you would have said the tour you had in the research and development command, monitoring and

developing and overseeing the undersea research program for the Navy medical department. That's where, to me, knowing you, you had the most influence of your whole career, I thought, anyway. You really did a lot of good things there.

DR. BORNMANN: But I also had a lot of frustrations. I'm telling you that when I look back at my career, I had more fun when I was a lieutenant than when I was a captain.

INTERVIEWER: Well, the fun goes away with responsibility sometimes.

DR. BORNMANN: It's a different type of satisfaction. 'Fun' is probably the best term to use for what you did when you were thirty. What you did when you were forty had a lot of responsibility. It wasn't just you. It was the people you were working for, some of whom you never met. But as I said, the entire quarter-century was just replete with all sorts of satisfactory situations.

INTERVIEWER: In that quarter-century, was there anything that you would consider your most important contribution to diving? Can you single out anything in particular?

DR. BORNMANN: Well, again, I'm not sure that any of them were all that important, particularly since we've turned the deep oceans over to the engineers and their vehicles. But I did help set up, or at least suggested, the establishment of a program for exchanging duties between medical officers of the Royal Navy and the United States Navy. I was a little startled when they canceled the flight surgeon exchange to change it to an undersea medical officer exchange. But that's the way they decided to do it. The exchange, I think, began when I got together with Eric MacKay at Lambertsen's lab in Philadelphia in 1963, and we said, "Hey, why don't we swap jobs?" It eventually happened. In 1970, I swapped jobs, not with Eric, but with David Elliott.

I was also the person who set up the additional duty for individuals in the Surgeon

General's office, to work in a chamber at the EDU and at NMRI. That lasted for what, twenty years? But [it] no longer [exists] as far as I can tell. The diving program at Bethesda has been transferred to the EDU in Florida. There is no longer any way for people who work in the Surgeon General's office to get diving or chamber pay. We had people out in the fleet doing magnificent jobs and they were the type of officers the Surgeon General wanted to come back to take important management assignments in Washington at BUMED. They were faced with giving up their submarine pay or their diving pay and taking a pay cut in order to be transferred to a very important assignment. It didn't work out the way I imagined it. But we were certainly trying to alleviate the problem. I think that we got some very fine individuals to come to BUMED. Whether they would have come without the chamber pay, I don't know.

INTERVIEWER: Did you have any disappointments? Can you recall any disappointments that you encountered in undersea activity, things that you would like to have seen differently?

DR. BORNMANN: Well, of course, one always is disappointed. You find that it stems from a difference of opinion and judgment with your superiors. Often, they have, in subsequent years, been proven correct. In other cases, their decisions have been proven incorrect. Whether or not it has been adjusted is just a matter of history. There are some people that still think that the Navy's giving up the blimp program was a terrible mistake.

INTERVIEWER: That's true. If you had it all to do over again, would you follow the same course?

DR. BORNMANN: Yes. That's kind of a difficult hypothetical question to answer. But the simple answer is 'sure.' I'm completely satisfied with the course of my career. Let me

say further that when I go to reunions in places like Panama City, and see the young people at the diving school and the experimental diving unit, and when I go out to San Diego and see the people working in the submarine area, and in the North Island Headquarters for the DSRV's it is a different Navy. It's a different culture. It's a different time. But if any young man asks me, "Is the Navy a place that I should consider for a career?" My answer is a resounding and unhesitating 'YES!'

INTERVIEWER: Good. In the past half-century, what would you consider the most significant achievement made in undersea technology?

DR. BORNMANN: The ROVs and AUVs were the most significant. I mean, I'm an old man. I'm 72 years old. I think about the status and the capabilities of medicine when I was a medical student and graduated with an M.D., and what the Navy can do in the ocean this year, compared to what they could do in 1960. When I got into the program, it was a different world. You made a small contribution, and someone else built on that, and then another person built on that, and you end up with a different world. That's what's happened in the last half-century, in both medicine, and in Navy technology and capability.

INTERVIEWER: If in your Navy career, all the barriers that you encountered in doing things were removed, and you had been given absolute authority to do anything you wanted, what would you have changed or done differently, or have developed differently?

DR. BORNMANN: I can't answer that.

INTERVIEWER: Why not?

DR. BORNMANN: Well, I can't answer it because I've never thought of it. Basically, I'm

an individual that respects discipline and authority. Even though I've disagreed with decisions that have been made, as I just said, who am I to say that I'm right and they're wrong? History will have to make that determination, and I'm not sure that even history is clear in its judgments. I had no great overwhelming disappointment, if that's what you're looking at.

INTERVIEWER: No. I'm not necessarily looking for a disappointment. I just wanted to know what would you have done, or [who] you would influence to do [things] differently, or develop something that wasn't developed and those kinds of things.

DR. BORNMANN: Well, again, as I said, when I retired from the Navy, I was confident that the people who remained on active duty were thoroughly capable of running it without my advice or assistance. I'd had my time. I enjoyed it. Then, it was their time.

INTERVIEWER: In putting this book together for the Office of Naval Research, we're looking at a hundred-year timeline. Can you identify three top events in the past hundred years that, in your thinking, changed the way that we view undersea technology today, and the philosophy of Man in the Sea?

DR. BORNMANN: Well, let me answer in a little different way than you're thinking. Gunner Stillson and Dr. French came out with their report on deep diving, and then the first modern Navy diving manual in, I think it was 1914 and 1915. When they did that, they thanked the Office of Naval Intelligence for providing them with information and reports on what was going in the United Kingdom and Europe.

Today, we have exchange officers. We have information exchange programs. We have a memorandum of understanding. The Office of Naval Research has contacts in almost every European laboratory, Navy and otherwise. Our associations, like the

Undersea and Hyperbaric Medical Society, are not parochial organizations, but international societies. Our meetings are an international exchange. When we talk about what's been accomplished in the latter part of the century, we're talking about international program accomplishments, not just successes of the United States Navy. I think that's the biggest change from 1903 to 2003.

INTERVIEWER: In the first half of that hundred year timeline, the navies of the United States and other countries were unquestionably the leaders in undersea technology and the development of that technology. A lot of the Navy divers then left the Navy and went into the commercial diving field, and continued developing what they had learned in the Navy. Neither of these seem to be prevalent today. Why?

DR. BORNMANN: Well, you're talking about in the 1960s. I mean, you started out with a hundred years, but you're actually talking about the 1960s and the 1970s. Well, there are two things. First, that the specific operational requirement for the Navy today has reverted back from what it was announced to be in the 1960s. Second, commercial diving has recognized its role, and has actually set up civilian diving training programs so that they aren't so reliant on the divers who retired from the Navy, or who didn't reenlist.

There has also been a reduction in human diving on the outside, as well as in the Navy, due to the fact that we have underwater machines that will do things much more safely than human beings could, at a deep depth. Once you've got a machine that can do that, and it can work at sixty feet or six hundred feet, it is basically still cheaper than human divers.

INTERVIEWER: Would you say, then, that developing underwater vehicles or machinery should be our focus in the future, rather than Man in the Sea?

DR. BORNMANN: Well, the human eye, fingers, and brain are miraculous creations. You're never going to be able to eliminate that from work under the sea. What you're talking about is the safest and most effective way to utilize the eyes, hands, and brains of a human operator accomplishing work under water.

INTERVIEWER: In which of the major accomplishments in the development of undersea technology did you have a major role? Try to focus on some of the areas, like what was that development for? Why was it important? What was your role in developing that technology? Who else made it happen? What technology was used to make it happen? If it went wrong, why did it go wrong?

DR. BORNMANN: It would be very difficult for me to answer that. Basically, I think of myself as sitting in the catbird's seat, watching a lot of fascinating things happen. I didn't have an essential role. There's no question that they would have happened had I not been around. But I saw some wonderful things happening.

**UNDERSEA & HYPERBARIC MEDICAL SOCIETY**

**ORAL HISTORY OF THE MAJOR PARTICIPANTS  
IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS**

**INTERVIEW OF  
REAR ADMIRAL BRAD MOONEY**

San Diego, California  
Wednesday, September 24, 2003

## PROCEEDINGS

INTERVIEWER: Brad, I was wondering if we could start off from the very beginning. Where were you born and what was your childhood like, and how did you actually get involved with the U.S. Navy?

RADM MOONEY: Well, I was born in Portsmouth, New Hampshire. That was fortuitous. I was born in 1931. When I was a youngster, just before World War II, Portsmouth was building submarines and, of course, built submarines throughout World War II and afterward.

One of the things I guess that helped the course of my life, and I guess I shouldn't have said it 'helped,' but it was the sad sinking of the USS *Squalus*. I remember that well. You've seen the picture, I'm sure, of the bow of the *Squalus* coming up, slipping out of the sling and going back down.

INTERVIEWER: Yes.

RADM MOONEY: Well, I was on the scene that day. It turned out that a friend of the family was a banker in Portsmouth. He had a Crisscraft [sp?]. He took us out to that area, and the only time I went out to that area where the salvage was going on for *Squalus*, and it happened to be the day it came up and slipped out. That, of course, was a big issue.

INTERVIEWER: You would have been eight years old at the time?

RADM MOONEY: Yes, I was. I recall the salvage fleet bringing the *Squalus* up the Piscataqua River and taking it to the Navy yard. I remember the pontoons on each side of it as they towed it up the river. Later on, after my parents had divorced, I went to live during part of the school year with my mom. Harold Prebel (?), who was the first survivor to come out of the barrel on the *Squalus*, lived across the street. I got to know Harold Prebel very well. Also, during the whole

*Squalus* disaster, my dad was the president of the American Red Cross chapter in Portsmouth. He was involved in helping the families of the people who were on the *Squalus*.

Coming from a submarine town, I wanted to get into submarines. My high school teachers urged me to go to the Naval Academy. I went there right out of high school, a couple of weeks after I graduated, in 1949. I went to the Naval Academy and graduated from there in the class of 1953.

During the summer that I was on leave, between my second and first class years, I was at home in Portsmouth, but I volunteered to serve on the USS *Tang*. The *Tang* was up in the shipyard at that time. They put me alongside the engineer on the *Tang* and every day I was home I spent a good deal of time working in the shipyard on a real live submarine.

After graduation, I went to an APA, troop transport for a year. In those days, you had to be qualified as an OD underway before you could go to submarine school. When the year was up, I was qualified as an OD and I went to submarine school. I was married December of 1953. Four or five days later, we went to the Mediterranean for six months. When I came home in July from the Mediterranean, I had hardly gotten to know my wife. I went to submarine school and I stood last in my submarine class. I went through most of the academic board meetings, and for the one I didn't go to I volunteered to serve tea. But I think I spent a lot more time with my family than I should have, and a lot less time with my books.

However, and this may help some other youngster sometime, after I graduated, I went to the club in New London for lunch with my wife, and our speaker at graduation was Joe Grenfeld (?), who was a famous World War II submariner. He came over to me and said, "I understand you're the bucket man in the sub-school class." I indicated that yes, I was. He said, "Well, so was

I.” Then, he started listing to me a number of people who were bucket men in their classes and had done very well after that.

I brushed myself off and served on submarine USS *Burfish* in Norfolk. I wasn't the first person to qualify in submarines in that class, but I was the first person to qualify for command of a submarine. I knew I had a lot of catching up to do because I didn't do well in sub school.

After the *Burfish*, I went to Sarda, New London. After Sarda, I went to sub school to teach. I didn't go to teach the subjects that I had difficulty with, but I taught tactics. I did that for a year, and then I taught advanced tactics, PCO tactics, for another year. Then, I went sub lance staff.

The staff was split. The operational staff was in Norfolk. The logistic, training and personnel staffs were in New London. I was there on the training staff. That was during the time that about one Polaris boat per month was being activated, so we had to train the crews. Essentially, one crew a month had to come off the line. That was a challenge. While I was there, were I going to go into the nuclear program, I would have applied but didn't. I wasn't ready to accept Admiral Rickover as my religion.

INTERVIEWER: Was he notorious at that point?

RADM MOONEY: Oh, he was notorious at that point. George Peperidy Steele (?) was at the desk next to me. He was the only nuclear person on subland staff. He was the first one who came there. He was in a very difficult position, because he was obviously Rickover's man on the staff. He had some loyalty to Rickover, as well as some loyalty to our boss, who was Admiral Dasby (?). He asked me why I hadn't applied for nuclear power training, and I said, “Academically, they probably wouldn't accept me because I was the bucket in my sub school class.” In any event, I wasn't ready to accept that as my religion. We discussed that a bit.

Later on, there was a submarine in the New London area from which they had just fired both the executive officer and the skipper. I was asked if I would like to go there and be the executive officer of the boat. It was the USS *Sea Robin*. I volunteered and went. We had a good skipper. We had come in within two days of one another. We went to the Mediterranean about a week after I reported aboard. The crew just needed some leadership, I think. It was a good crew. We had a very successful tour in the Mediterranean. I came back from that around Thanksgiving of 1963. We were in the Mediterranean in April of 1963 when the USS *Thresher* was lost. Our next port of call was, I think, the Thursday before Good Friday in April. We went into Monaco. That was experience of a lifetime, really.

It [was/is] the official residence of Prince Rainier and Princess Grace, and as soon as we got into port, [they] put their flag at half-staff. We were invited to go to their home for a Saturday night affair, at which a Monagast pianist was to play eventually, and television in Philadelphia [?]. David Niven was there, and so was Jessie Royce Landis, who had played Princess Grace's mother in *High Society*, I think the movie was called. It was quite an evening.

My skipper was actually born in England and came to the United States at age three. Johnny Johnstone. We went to have a beer in the hotel de Paris, in Monaco. While we were sitting there he said, "You know that gent over there is Edmond Murray, Winston Churchill's bodyguard? Let's invite him over for a beer." He went over and said, "You're Edmond Murray, aren't you?" He was. Edmond Murray joined us in a beer. He said, "Sir Winston's here in the hotel." After a discussion of a variety of things, Ed Murray indicated that Sir Winston loved westerns. We went back to the ship that evening. The next morning, we asked for volunteer movie projection operators. We asked how many guys wanted to show movies to Winston. Every one of them volunteered.

They went over to the flagship of the 6th fleet and got the best westerns that they could find. For the rest of our time that we were in Monaco, every morning, afternoon and evening, a movie projection officer or sailor went and sat with Sir Winston Churchill and showed him western movies.

They wouldn't allow people in uniform to go to Monte Carlo, and we were having social events for most of the wardroom when we had to be in uniform. I asked the wardroom if any of them would volunteer to turn their civilian clothes in so that the sailors could go ashore and go to Monte Carlo. Well, we gave them to the torpedomen in charge on watch in the forward torpedo room. Every afternoon and evening, seven suits of civilian clothes went ashore. They ended up in Monte Carlo. Troops went in there and had a wonderful time. Otherwise they wouldn't have been able to go in there, as they were in uniform. We had good cruise there.

INTERVIEWER: You had a chance to meet with Winston Churchill.

RADM MOONEY: Yes.

INTERVIEWER: Now, I understood he was like a night owl. He would be up until three or four in the morning.

RADM MOONEY: That could be. We didn't stay up that late with him, you know. I think most of our movie projection guys came home by about ten. He did three movies each day. We wanted to get home from that trip by about Thanksgiving. I was asked if I would like to take the USS *Trieste*. The reason for that was that I had headed in for an ocean PG and a request was sent to PG at Monterey. I had put in for the USS *Dolphin*. The *Dolphin* had slipped several times, and I found out that I had passed *Dolphin* by, as it turned out. I said that I'd love to go to the *Trieste*. I was advised by most of my friends, seniors and peers not to do it. It was sort of a dead end.

That tour on the *Trieste* changed my life. I went to it in January of 1964. It had a new bathyscaphe. It wasn't the original Piccard bathyscaphe. It was the USS *Trieste II*. It had a different hull. We had to work that up, and I did some scientific dives off of San Diego for geologists, physical oceanographers and marine biologists.

We found the deep scattering layer, lived in it one day and followed its migrations up and down in the mid-water. Then, we packed it up and sent it to the East Coast and went back there to look for the *Thresher*. The bathyscaphe had looked for the *Thresher* in 1963 and found some of the debris, but the hull hadn't been found.

Admiral Rickover's staff, of course, was anxious to find out if there was any radiation there. Also, Admiral Joe Grenfeld was anxious not to bring any further grief to the *Thresher* dependents, so they called it a 'research' operation rather than a 're-search' operation. It was under the auspices of ONR. Frank Andrews was our OTC. On about the 18th of August 1964, we found the hull. We took readings around the hull, but there was no radiation there. We were in good shape. We took water samples and all that. We came back from that and did a lot of dives for science.

INTERVIEWER: If I may go back, the cause of the *Thresher*'s loss was determined to be due to a ruptured pipe?

RADM MOONEY: It was a piping failure in the aft, yes.

INTERVIEWER: How was that determined? Was it from what you observed there, or were you able to bring parts up?

RADM MOONEY: No. We didn't bring any parts up. It was pretty much from what was observed. It was sort of like a crime scene investigation, or CSI, like you have on television these days. They put all the evidence together and came up with a piping failure aft. There was a

sealed brace joint on a seawater system. There were two valves before that. They were welded valves. There used to be a sea valve and a backup valve. Behind that, you could have your sealed brace things. I believe that one of those valves wasn't there and it [what is 'it'] went immediately to a sealed brace joint. The technique for measuring the bond in the sealed brace joint was, I thinkn, faulty. It was the best that we had, only it had gave more of a bond that actually existed and that was what they felt let go.

In any event, I had friends on there. I saw the wife of my closest friend this last weekend at the 50th reunion that we had in Annapolis. Her name is Edna Denoa (?). She lives in Rye [where]. Her husband was lost on the *Thresher*. I met with her son. It was several years before I could face her. Then, I was at a class reunion in Annapolis and came out of my hotel room and bumped into her in the passageway and we grabbed each other and stood there and cried. That sort of broke the ice, because I couldn't face that lady. But after that meeting, Mike's son asked to see me and wanted to know what it was like down there where his dad was. We had a long discussion about that. His son was at this reunion that I just came back from. They're doing well.

INTERVIEWER: Now, you didn't have all the technology we have today as far as search and navigation was concerned. Can you describe the typical search operation then?

RADM MOONEY: Yes, I can. As a matter of fact, I'm supposed to speak at a luncheon that's going to be in New London, on the *Alligator*. I'm not sure why I'm speaking, because Clive Custer and Bob Ballard are going to be there. I think I'm the comedy relief. In any event, one of the things that I want to talk about there is the technology that's available today as opposed what technology we had back in those days.

By today's standards, navigation on the bottom was not existent. It was done by eye. In 1963 and 1964, they dropped three-dimensional things with sash weights. They put a window

sash weight on them. They colored various colors and they were all numbered. From a surface ship, let them go so that they would be little avenues down there that you went around in a search. Of course, they went down through the water column much in the same fashion as leaves drop from trees. They didn't go down in an orderly fashion at all. They were all spread around the place with no orderly numbering or color system at all, and it was terrible. They impeded the progress more than they did anything else. But we, of course, were let off on the surface at a datum that they felt was the best datum possible for where the *Thresher* was.

INTERVIEWER: Was this for the ran (?) or something?

RADM MOONEY: Yes. There was a surface ship there and it dropped us off. The vagaries of the water column took us to different places between there and getting down [to] 8,200 feet. Once we get down there, we saw some light debris on a couple of dives, but we had a fire. We lost all propulsion power on the bathyscaphe on one of our first dives in 1964. We tried to reset the circuit breakers but they wouldn't reset.

It involved Larry Shoemaker, our chief scientist, McKenzie, and me. There was a little bit of current. Shot was a commodity in demand, because we used shot, you know, for ballast. We'd only brought so much shot with us from the west coast, and it was hard to come by anyway. They'd [who] steal all of our shot.

INTERVIEWER: Now, was the shot like BBs?

RADM MOONEY: Yes. The way you controlled the bathyscaphe I liken to a dirigible. A dirigible has a rigid gas bag. If you take the gas out of it, it retains its shape. With a blimp, if you take the gas out of it, the shape collapses. It's filled with aviation gasoline. But in there, there's a silo forward and aft that's full of steel alloy shot. At the bottom of that silo is an electro-magnet. If you have a current, the electro-magnet will magnetize the current in the orifice and it forms its

own valve. If you interrupt the current, the shot will flow like sand out of an hourglass and you get light. In the center of the bathyscaphe there was a tank that you could release the gasoline with. It was replaced by water, so you got heavier. It was those two things that played to give you the buoyancy that you needed, or the neutral buoyancy.

When you went down, there was some heating by the compression of the gasoline. On the bottom, there was a degree of cooling of the gasoline, so you got heavier. We were getting heavier, and thought it was just because of the cooling. When we surfaced, we found out that we had burned a hole in the hull and it was aviation gasoline that we were losing the entire time.

In any event, we stayed down for about seven hours and let the current take us, because we figured, "Why abort the dive and lose all the shot? Hopefully the current will take us where we want to go," and it did. We got into some pretty heavy debris and thought if we got underneath it, we would not be able to drive ourselves out.

When we got into where it was big, we decided to surface. Once we got to the surface, you had to come out of the bathyscaphe, go topside and shut two ballast tank vent valves on either end of it. When we did that, we were waist-deep in aviation gasoline. We saw the electrical distribution box burned open. A big cable that was about three inches in diameter had cooked like a hot dog. The skin on it was off. We'd obviously had a very large discharge fire, an electrical fire.

We went back to Boston and I immediately called the captain, Russ Bryan. He later became Chief NAVSEA. He was, I think, production officer of the Portsmouth Naval Shipyard. He said, "Come to Portsmouth right away. We'll help you." We went and got up there at about two in the morning. He had assembled a team of experts, his engineers. We told them what the problem was, and they said they would take care of it. They took the whole electrical system

apart in a month. They rebuilt it, tested it and took it apart. They took it to Boston, put it on the bathyscaphe and tested it. We went to sea again in a month.

During that month, Jennifer was born, my youngest daughter. The story I have just told you is one that I mentioned several years later to a person at the Pentagon. That person said, "Well, we've got a project that we want to name, and we have just gotten the name. We'll call it Project Jennifer." If the people that read this are interested, there's a book by the name of *Project Jennifer*.

INTERVIEWER: I've read that.

RADM MOONEY: It will tell them what it's about. At that time, of course, it was very classified. Anyway, we went out and made some more dives. On one of those dives, by luck, we landed on top of the hull of the *Thresher*.

INTERVIEWER: Was that the dive on which you'd lost power? You said you drifted.

RADM MOONEY: No. It was more than a month later. They had fixed the electrical system, and then we started diving again. On about the 18th of August, I think, we made a couple of dives after we'd been repaired. Frank Andrews, John Howland and I made the dive and we landed on the hull. We then saw why they hadn't been able to find the *Thresher* with sonar. It had gone down and dug its own hole. The best that way I can describe it is that it was sort of like a sand pit, and it had swished around and come to rest up against the wall of the sand pit on one side. The other side was totally open.

When we landed, we landed ninety degrees from the axis of the hull and could see the bottom on the open side, and we wondered why we couldn't get down to the bottom. Then, we were letting gas go and so on, and we couldn't get down there. We could see it about thirty feet

beneath us. We got a little bit of buoyancy, swung ninety degrees and there was the hull. That was when we first found out what it was.

It was a big hole in the hull with a piece of metal sticking up. Of course, to us, that piece of metal was a potential can opener for our 3/16-inch hull that we had [on the bathyscaphe?]. We very gingerly maneuvered around and got a lot of pictures of it. Then, we went down to the open side and scraped paint off the bathyscaphe on both sides as we went down in that hole. But we got fresh water, or salt water readings, which we brought back for radiation-measuring purposes.

INTERVIEWER: It was really a stroke of luck.

RADM MOONEY: Oh, yes. But it had dug a hole, so if you were off to one side of it and had sonar, you were shooting your sonar beams right over it, across the sea floor. In any event, that was over. We went back to San Diego and did a lot of dives for science. Then, they were going to do some reconfigurations on the hull of the *Trieste*. We lost the hydrogen bomb off of Spain. An Air Force bomber was re-fueling from a tanker and they collided and crashed. Three H-bombs went into the tomato fields of southern Spain and one went into the ocean. I was sent over there. I was the gent who had the responsibilities for [searches?] below 300 feet. A diver named Red Moody had the responsibility [for searches?] above 300 feet. I had the *Myzar* (?) with a towed camera sled. I had the *Aluminaut* and the Cubmarine. I also had *Alvin*. They were submersibles, except for the *Myzar*.

INTERVIEWER: The *Thresher* wasn't part of it.

RADM MOONEY: No. But the experience that we had with *Thresher*, of course, gave us some experience of how we should do it. Once we got over there, the first thing that was obvious was that there no common navigation system, so there were multiple contacts that couldn't be correlated to one another. They set up a good, short baseline navigation system over there on the

surface, at least. Then, we had pretty good data that had been sort of overlooked. There was a fisherman named Seymour Otes (?), who was sort of the head of the fisherman's union in Pompaneria or Lagartera, Spain. They were upset because they were denied fishing in the area. They thought there might be radiation and that sort of thing.

However, before I had gotten there, they'd taken him to sea because he said he saw half a man (?) in a parachute go in the water. They thought that might be the bomb. He lined up the mountains appropriately and said, "It's right here." They marked that spot, but the Navy folk who were there and used to very precise navigation and cuts, not just eyeball navigation, discounted what he had given them.

But going back to Portsmouth, New Hampshire, the lobster fishermen there navigate like Seymour Otes was navigating in Spain. After I'd been there a couple of days, I went over to the bar in Lagartera with John Lindbergh. The Air Force gave us a Jeep to drive there, and we found Seymour Otes in a bar and got him to sea on a minesweep[er]. We said, "Tell us again where the bomb went in," and he said it was about ten yards from where he indicated the first time. Immediately, that became a firm datum.

We figured that if the parachute on the bomb did not open, it would have gone down like a rock. But if it had opened, it would have gone with the current. We figured out what the currents were. That gave us a search area, and we made some segments for that search area and started diving in them. The *Aluminaut* was not very maneuverable, so we gave it the areas that were more flat and *Alvin* got the areas that had really rough terrain. *Alvin* found the bomb. Then, we tried to recover it. We hooked a grappling hook into the shrouds and straps of the parachute. Upon lifting, they cut through those shrouds and straps. That can be done on anything. It doesn't have to be terribly sharp. But you can cut through the nylon very easily when it's under tension.

We dropped it and the parachute billowed and the currents took it away. It took us a couple of weeks to find it again.

One thing that I had been taught when I was in small vehicles [training?] was to never have two small vehicles in the same area. But I violated that. *Alvin* was down there. She found the bomb and was sitting beside it, but it she was almost out of battery power. We sent the *Aluminaut* down and had a rendezvous at the bomb with both vehicles' lights on.

Normally, with backscatter, sixty feet is the world, you know. Because the two vehicles had their headlights shining at each other, like on the road in a storm, they could see each other further away. They made a rendezvous and *Aluminaut* came in and babysat the bomb until *Alvin* could get back squared away. Then, we put a marker down beside the bomb so that we could get back to it more easily. I guess that was the first time we really used underwater markers like that. That gave us an assist. We had a cooperative target down there to go after.

This entire story is compressed. I figured out how many days we were doing this. We also used *Curve*, which was an ROV that recovered torpedoes at the laboratory here in San Diego. It went in close with the grappling hook to get a certain number of straps and shrouds on the bomb so that we had a couple hundred percent safety guard because we were going to lift it this time. But the parachute billowed because of the wash from the *Curve*'s propellers. We could see the pictures on the surface with the cameras, so I said, "Drive it in there."

They drove *Curve* into the parachute and got it totally tangled in it. Admiral Guest, bless his heart, was an aviator, and this was all foreign to him, you know. But he had been the one who told us how many straps and how many shrouds we should have. I could not tell him I had that number of shrouds and that number of straps, but I felt pretty confident that we did. We had totally entangled the *Curve* in the parachute, and he said, "Cut it loose."

Some of my friends at the Naval Electronic Lab, which is now the Spaywar Center (?), were there with the senior civilians whom I had known for a while. We had some discussions, Admiral Guest and I, as we went along. I think he respected my advice because I was about the only guy there who had done any deep sea work. They said to go in and convince him otherwise, because they didn't want to cut it loose. Neither did I.

INTERVIEWER: Why did he want to have it cut loose?

RADM MOONEY: He wasn't assured that there were enough of the straps and shrouds to lift it safely, you see. I went into the wardroom on the ASR. I think it was Blackbart ['Black' Bart?] Bartholomew, in his book about divers who quoted me or maybe Alvin quoted me in his book on the Sea Baby. In one of those books, I'm quoted as saying, as I went into the wardroom, "This is dumb as hell, sir," which is what I said.

Admiral Guest and I had a discussion for about three hours, and it was heated. I was a lieutenant commander. I figured, "I'll never get anywhere after this." We had a heated discussion for about three hours, and finally he said, "All right, go ahead," and we lifted the bomb. Then, we had to display it before the whole world. The news media was there.

INTERVIEWER: I suspect there was a lot of pressure from Washington during this whole operation.

RADM MOONEY: Yes. A couple of the sidelines were interesting, I think. Every day, Admiral Guest had to send a secret message on the status of the operation. We knew that there were e-link stations that the media had set up along the coast of Spain. They were also listening to our UQC transmissions between the ship and the submersible, and I stayed off the cruiser most of the time. We had established a code and changed it everyday. A person on the sub that was diving that day had a copy of the code. I had a copy of the code, and a person who was in the CIC on the cruiser

with Admiral Guest had a copy of the code. It was made up of the colors of the rainbow and the characters in the *Peanuts* comic strip. 'Lucy-Purple' meant something, for instance. We could talk to one another with this code. It changed every day. He was sending secret messages to Washington.

The next day, *The Paris Tribune* had almost verbatim what he was sending in the secret message. Guest decided that every day, he was going to take one ID (?) off the message. The day he took the ID for our Ambassador from France, it didn't appear in the *Tribune*. He put it back on and it appeared in the *Tribune*. He took it off and it there was no story in the *Tribune*. He said, "I'm not going to send him anymore messages." Biddle Duke was the Ambassador.

At about that time, we had dropped the bomb. Biddle Duke insisted that he get the word by such and such a time, as to whether we had found find the bomb or not. The day that we found it the second time, I wanted to make darned sure that we knew where it was. We had all the ships go over a buoy, calibrate their navigation equipment and come out over the site. [I/the ships?] was talking with this code to the submersible to find out what the slope was, and all the questions I figured Guest would ask me, and I didn't know that he had a deadline.

At about a quarter to four on the day he had to tell Biddle Duke the answer, I spurted this information into the cruiser, and he received it. Later, he got a hold of me and told me how he had a deadline and we [had to] beat it by 15 minutes or he was going to have to say no. That was a tangent on that whole operation. Do you have any more questions?

INTERVIEWER: I know that Hollywood took a lot of artistic license in the movie *Men of Honor*.

RADM MOONEY: Yes.

INTERVIEWER: Was there any indication that the Soviet Union was in the area?

RADM MOONEY: Yes. There was a trawler. A trawler came through one day and a submersible was on the bottom. I think it was the ASR, or it may have been the USS *Hoist*, a salvage ship. But I asked them to go out, shoulder that trawler and do everything short of a collision to get them out of the way. They did that and the trawler moved out because we didn't want them operating overtop the submersible. That was the only evidence that there was any Soviet reaction there.

INTERVIEWER: The movie has a scene of the bomb being brought up and the diver, Chief Brasier. Was it actually during the lifting of the bomb that the cable broke or let go?

RADM MOONEY: No, it wasn't. That was Hollywood. There was good deal of fact in that movie, but there was some Hollywood in it, too.

INTERVIEWER: My understanding is, being the officer in charge of say, the *NR-1*, you were on the upward track in the submarine community. Was the *Trieste* looked at with the same kind of detail? Were you really on the upward track to being the officer in charge of the *Trieste*?

RADM MOONEY: No. Remember that I mentioned to you that people advised me against going there because it was sort of dead end. Don Walsh had already made his dive to the bottom of the ocean, seven miles down. What's left type things [What was left to do?]. It seemed like an adventure that I wanted, and so I was glad to do it. You can see it changed the rest of my life, because after the time I had *Trieste*, I got involved in deep ocean work, and here I am at 72, and I'm still in deep ocean work.

I had command after I got home from Palmyrus. I had a diesel submarine in the Pacific. Then, I made a couple western Pacific deployments during the Vietnam War. I came back and served in the Pentagon. The legacy of the *Thresher* was the sub-safe system, designed to make our submarines safer. They really examined the whole slew of the systems down there and found

several that were in need of enhancement. Those changes were made and are apparent in our submarines today.

The deep submergent [submergence?] systems review group, Admiral Stephens' group, came out with a report on the *Thresher* and the improvements that ought to be made in search, inspection, recovery, large and small object recovery, diving and man [in?] and the sea. My first duty in the Pentagon was to go through that report. It wasn't finished then. But I worked with the people on the report, and went through it and implemented the elements of that report.

After that, I went out to Sub-dev (?) Group One and had to live with my sins. The things that I had sent out of the Pentagon were things I had to live and comply with out at Dev Group One. Before I left the *Trieste*, it had moved from the laboratory at the NEL, or the Naval Electronics Laboratory, to the fleet. It was a fleet asset that later became the nucleus for Sub-dev Group One, which is now Sub-dev Five.

After a couple of tours at the Pentagon and the Dev Group, I had a shore command in Charleston. Then, I had another tour at the Pentagon. Then, I had one at the Naval Training Center in Orlando. In Charleston and Orlando, I was sort of like a city manager. At the naval station in Charleston, I was like a city manager with a waterfront. At the training center in Orlando, I was like a city manager of a base at which your main battery was schoolhouse, you see.

After that, I went to Washington and was assigned the Drop 11, which was total force planning and included education programs and training. I was there for three years. Then, I went to the Oceanographer of the Navy for three years. Then, I went to Chief of Naval Research for four more years.

My duties during the last 25 years I was in the Navy were part of the things that I had learned when I went into the deep ocean program in 1964. Since retirement, I've been able to work as a consultant with companies that have been involved in deep ocean work, and I am still doing that.

A couple of years after I got out of the Navy, my consulting was interrupted when I had an opportunity to go to Harbor Branch, and I was the president and managing director of Harbor Branch. That was fun, because they had a couple of submersibles there that could go to 3,000 feet, and other assets and good scientists. I've pretty much run out of lies, now.

INTERVIEWER: You have certainly had a very interesting career. You mentioned Project Jennifer. I'm kind of interested in that. When was that, in 1975, or so?

RADM MOONEY: I think it was in 1972.

INTERVIEWER: Did you have any involvement in that, other than the fact that the project was named for your daughter?

RADM MOONEY: No. I knew of it, and it was named for my daughter. I forgot one item. When I was chief staff officer at the Dev Group in 1972, the United States had lost a classified package in the Pacific, and we had to go out there and find it and recover it.

It happened in April of 1972, I think, at about the same time Jennifer was going on. I was OTC. I didn't make the dive, but *Trieste* went out there. We didn't search for it. Navigation had improved tremendously. I said that technology was bad. Fred Spiese (?) from the Marine physics lab searched for it and found the item that we were to go after. He gave me the position of three transponders on the bottom of the Pacific, on the back of an envelope, literally. He said, "This is where you have to go." We went out there. The first time we got into the area the *Trieste* was

being towed by the *Apache* and it was in an ARD, so that was sort of home [?]. I was OTC. I wasn't skipper at the time.

We sort of skidded into the position where we thought we were [supposed to be] because we wanted to make sure that we knew what the wind and currents were. The first time we pinged we found all three of those transponders. There had been a lot of advances between 1964 and 1972. After that, we were at the whim of the weather. We were just about in the place where the trade winds and the Siberian lows fought for control of the weather there. It would change in a matter of minutes. But we went out in October. The weather window pretty much was shut by the time we got there, and it took until April, but we weren't out there all that time.

In April, we went down and recovery it. It was at 16,400 feet. At that time, and for about ten years after that, that recovery was in the *Guinness Book of World Records*. I think it was the deepest recovery that had been made up to that time.

INTERVIEWER: It was in the *Guinness Book of World Records* even though it was a classified dive?

RADM MOONEY: Yes. We said that it was a classified package.

INTERVIEWER: ONR has been involved, of course, in a great deal of deep ocean exploration. What did you see, as the CNR, during your detail there? What was going on?

RADM MOONEY: We founded *Jason*. Of course, we also funded *Alvin*. We needed to have a test bed to test *Jason*. Robert Ballard and I had been friends for a long time. Ballard was over by the Azores and was coming home. We convinced John Lehman, the Secretary of the Navy, that rather than build the test bed to test *Jason*, it might be wise to sort of slip by where we thought the *Titanic* was and test it there. That was all tongue-in-cheek. But on the way home, Ballard went by the place that was the most probable site of the *Titanic* and found it.

INTERVIEWER: He wasn't actually an exploration to find the *Titanic*? It was just on the way home?

RADM MOONEY: It was just on the way home. The federal government really didn't fund the search for *Titanic*. But since we were testing our *Jason*, we he swung by there to see if he could find it. He swung by there and found it. I met him when he got into Woods Hole. I don't think that Bob would be opposed to my telling you this. Like most people who have achieved some of the things that Bob Ballard has achieved, there is an ego there. But people need to know the other side of that. I was at National Geographic when he gave a talk on the *Titanic* and presented the pictures he had. He got to the stern of the *Titanic* and he stopped and changed the subject very quickly. He'd read so much about the *Titanic* and it almost got as though he knew the personalities of everybody there [on the *Titanic*?].

The stern was where everybody went to try to save him or herself, so there was chaos on the stern of the *Titanic*. That was really where people died. When he found the stern on the *Titanic*, they immediately stopped and had a memorial service. That was the first time that the *Titanic* was found, but he couldn't talk about it. Later on, when I was the Chief of Naval Research, he came by the office and I said, "You seemed to choke up when you were talking about the stern of *Titanic*." He told me that he did.

I told him that I couldn't bear to see Edna Denoa after I had the found the hull of the *Thresher*. The two of us sat there in my office. I cleared my schedule all that afternoon, and the two of us sat there talking about what those two events meant to us. We cried like babies, talking about it. It was really horrible for me to see the way *Thresher* went, and it was horrible for him to see the stern on the *Titanic*. [insert] When he came back to port about two weeks before that, I'm

trying to think of the gent's name at NRL. He'd gotten the Nobel Prize in chemistry. I'm trying to think of his last name.

INTERVIEWER: We'll find it and put it in. [insert]

RADM MOONEY: I left my office and went over to NRL to congratulate him and asked, "What obligation do you feel to the youth of this country?" He hadn't thought about that. Later on, during the National Science Fair, I invited him and he gave out all of the ONR scholarships to the kids. His wife's name is Anna. She might well someday get the Nobel Prize. If she does, it will be the first husband and wife since the Curries, I think.

Anyway, when Ballard came back from the *Titanic*, I asked him the same question. He said he hadn't thought about it. He said, "I'll tell you in six weeks." In six weeks, he came up and outlined the *Jason* program. That's still going well. Kids all over this country and other countries are able to witness things on the seafloor and control ROVs on the bottom, halfway around the world. He's really done a lot to educate youngsters on the ocean. That's the kind of guy and sensitive person Bob Ballard is.

INTERVIEWER: That's an interesting perspective, because I read a book that Bob Ballard had written about the animosity, I guess, at Woods Hole, that he felt with the faculty and the fact that many felt he wasn't doing real science.

RADM MOONEY: That's right.

INTERVIEWER: There was a lot of animosity.

RADM MOONEY: Yes. Well, I've talked to a lot of people who think he does 'gee-whiz' science. My answer to that is it may be gee-whiz science from your perspective, but since Jaques Cousteau, who has enlightened more people in the world to the importance of the ocean to

mankind than Bob Ballard? Maybe he is even equivalent to Jacques Cousteau. You probably get money to do your science, so don't knock Bob Ballard.

INTERVIEWER: I guess that one of Sub-dev Group One's primary missions was submarine search and rescue. Deep Submergence Rescue Vehicles (DSRVs), of course, are going out of service. There's only one left now, I guess. They are being replaced by another type of submarine system. First off, what's your opinion about the utility of the DSRVs while they were in service?

RADM MOONEY: While they were in service, they were the rescue system for the world, for submarines. To every nation that ran submarines we gave the template they needed to build their hatches, and if they built those hatches to that template and had a problem, we could rescue people from their submarines. It was for more than just the United States.

Of course, we've tested it on many of our allies' submarines, in transferring people and so on. Those manned vehicles were there, the *Turtle* and the *SeaCliff*. The *Turtle* and the *SeaCliff* were built for ONR as autotech (?) vehicles and someone forgot to put the money and billets up for people to operate them. Bill Cyril (?) used to be the supervisor of salvage and is still a good friend of mine. Bill called me one day and said, "You know it's going to be a real black eye for the Navy if they take the *Turtle* and the *SeaCliff* as soon as they're finished at the Electric Boat Company and put them up on the block." We were expanding the *Trieste* group and training people to run the DSRVs, so we carved out of those the people who ran the *Turtle* and the *SeaCliff*. They became the workhorses of the deep ocean fleet for a long time. I have a story that I think will interest you. We also had all of the training for SAT divers there at the Dev Group.

INTERVIEWER: IX501?

RADM MOONEY: IX501. On one Friday evening at five, I was still there doing some work and the yeoman answered the phone and said that someone wanted to talk to me. Someone got on the

phone and said there was a bomb on the IX501 it was going to go off at seven. We had seven divers at 300 feet, coming up from 1,000 feet, on the IX501. I knew where the divers in that group had their beer on Friday night. It was at the Brigantine here in San Diego, off by Shelter Island. We called there and got all the master divers back. We had about seven or eight doctors, submarine medical officers, and we called call their homes. Their wives were home, but they weren't home yet. We said, "When your husband gets there, turn him right around tell him to go back to the Dev Group."

Once we had assembled all the doctors and all the master divers, I asked, "What do we do?" They had a caucus, and talked and talked and talked. Their recommendation to me was to get an ambulance to the IX501. Get the submarine tender man [and the?] their hyberbaric chamber. Have the police on the base clear all of the roads between the IX501 and the submarine tender.

They put those seven divers on the surface. They had been at 1,000 feet for over a month and were decompressing at 300 feet, which normally would have taken three more days. They put them on pure oxygen, brought them up and put them in the ambulance. They drove them down to the submarine tender and put them in the hyperbaric chamber there. We squeezed them down a little bit further than 300 feet, and not one of them got a twinge.

INTERVIEWER: How long was it between the time they came up and the time they were back at pressure?

RADM MOONEY: It was probably less than twenty minutes. That was the first time in my life that I sort of handed my commission to everybody else, the divers and the medics there, because I didn't know what to do. They were the guys who had the knowledge. I didn't have that

knowledge. I depended one hundred percent on their best advice as to what we should have done. I did that and we lucked out. None of the divers were hurt. There was no bomb.

INTERVIEWER: We can edit this next question out. I've read that the DSRVs' real mission was not submarine rescue. Would care to talk about that? If not, I would understand.

RADM MOONEY: I think that's false. The real mission of the DSRV was submarine rescue.

INTERVIEWER: What's your opinion of the new submarine rescue system that is presently being developed?

RADM MOONEY: It has some integration problems that need to be overcome. It can rescue people at a little bit larger [?] angles than a DSRV system. Since we put the ASRs out of commission, we have no place to put the rescuees these days. This new rescue system provides a place to put the rescuees so that they can make a second trip down to bring up some more rescuees. In that sense, I'm not sure that whoever made the decision to put the ASRs out of commission really recognized that they were really cutting that capability. With the chambers that are transportable by air, they can put the people in and have a place for them to be while the rescue system goes out and makes a second and third and fourth trip. That's certainly something that is absolutely needed today.

INTERVIEWER: Now, there is the air-water interface that you have to go through. I guess that you did not have that with the mother sub before the DSRVs.

RADM MOONEY: That's right.

INTERVIEWER: When you were transferring to a mother sub, the crew would be under pressure with the DSRVs, though.

RADM MOONEY: That's true.

INTERVIEWER: There was that limitation, then.

RADM MOONEY: The limitation is that if a downed submarine or damaged submarine has people in it who are at an elevated pressure, they have to be discharged in an equivalent elevated pressure to decompress them, and we can't do that today.

INTERVIEWER: Along the same lines, there is the equipment that has been developed for submarine rescue, such as the atmospheric diving suit and the side suit. Is this going in the right direction?

RADM MOONEY: I think so.

INTERVIEWER: In your particular field, what has proven to be the one thing that has brought you the most satisfaction, I guess, in your entire career?

RADM MOONEY: That's hard to say. I've had so much fun.

INTERVIEWER: It sure sounds like you've had a lot of exciting experiences. Do you have any regrets or disappointments related to your career in undersea activity at all?

RADM MOONEY: Yes, but I'm not sucking my thumb. I put in for that ocean PG. I never got it. I never got a post-graduate course. Every time that I was selected for post-graduate school, it was usually while I was in the Pentagon, because I was sort of one of a kind. In the Navy, if they say can't spare you then you can't go. I never got to go to a PG course.

I became a sub-specialist in oceanography, and then a proven sub-specialist in oceanography. But I don't have a master's degree or a doctorate. I wish that I had been able to get a post-graduate degree. But I look back to see which tour I would have had to give up in order to get that degree, and I can't think of a tour that I would have wanted to give up.

My work now is with the National Research Council, thinking about [?] the National Academy of Engineering. I work with Ph.Ds all the time, and they don't seem to look down on me for not having a degree. I've had a lot of practical experience.

INTERVIEWER: If you had your career to live over, and thinking in terms of constraints under which you developed your career, what personal decisions would you change and why?

RADM MOONEY: I'll probably sound very self-satisfied, but I don't think I've got any regrets in that regard.

INTERVIEWER: That's fair enough. Of all that you did during your career, what would you rate as the most significant in advancing Navy undersea technology?

RADM MOONEY: Well, it's sort of a continuing effort. You can see that I was in at the very beginning of the deep ocean program in the Navy, other than the *Trieste*, when it expanded. I was there when all of the new things started and I got some new submersibles and started saturation diving. Started [?] other than *Curve*, we got a series of ROVs and so on, which has benefited the offshore oil and gas industries, not just the Navy.

The flow of technology for a while was out of the Navy, but I think that now there's a flow going the other way, from the offshore industries into the Navy. If you look at all of that, it has had a great benefit to mankind, I think. I have sort of have grown with it, or it's grown with me, whichever way you want to look at it. It's a whole continuum of things that brings me from first being a submariner [to my present position], or my toilet training up to today, as I am now consulting on those things.

INTERVIEWER: Along those same lines, you're saying the Navy has contributed a lot toward the offshore oil industry and so forth. Since the first half of the century, the Navy was the world leader in diving and underwater exploration.

RADM MOONEY: That's true.

INTERVIEWER: Since that time, many Navy divers and leaders in this area have gone on to the commercial diving field. Currently, neither of these facts seems to be prevalent. What are your thoughts on that? It seems as though the Navy has lost that leadership role.

RADM MOONEY: Well, let's talk about the transition first. Many of the people who were hard-hat divers in the Navy were exposed to saturation diving. Some of them became saturation divers. They went to work for civilian dive companies when they retired from or got out the Navy. They became instructors and some part of the leadership of those civilian dive companies.

They continue to contribute to the civilian side of diving, using the expertise that they got in the Navy. They were part of the transition. It wasn't just the equipment. It was the talent that those people brought to the civilian dive community. Now, as the offshore industry moved deeper, the hard-hat divers couldn't go that deep, so the industry went to saturation divers and then they decided, "Hey, maybe we can use ROVs to do this." They are going to use ROVs rather than divers, but that's a continuing transition.

That whole industry was able to grow because of the foundation that was in the military. It was inevitable. Because that offshore industry is so important to the world, it became inevitable that there was going to be more money for development, equipment, research and those things. That is only a small segment of what's important to the Navy. Now, the flow of technology is from the outside in. That doesn't bother me at all that that flow is coming in, because you can think back and well, we started it. You can look around today at the offshore operations and the people who are working on very deep operations, and they're sprinkled with Navy folk who are there in leadership positions, still doing it, only on the civilian side.

INTERVIEWER: As the former CNR and a person with the leadership role that you are now taking in consulting, what's your opinion as to what we in the underwater world should be looking for in the future? We should be looking ahead, I guess.

RADM MOONEY: We need energy. We need a high-energy-density power source. That limits all of the things in the ocean right now. The automobile industries and other industries could dwarf anything that we could put into the research of high-energy-density sources, so we've got to watch the advances in those industries very carefully and then try to transition that capability into the ocean. There's our big one. That's a hard nut to crack.

INTERVIEWER: I would say you've got a lot to reflect on, but I don't think you're the type of person who sits back and reflects on what you've done in the past. You have certainly had a very full and satisfying career. I thank you for sitting for this interview.

RADM MOONEY: It was my pleasure. It sort of surprised me. Some things came up that I hadn't thought about for a long, long time. You can see that I just had a lot of fun. Something that's sort of interesting is that the kids that are in the industry today are just so bright. They are so much brighter than we were because, of course, they didn't start from zero. There was some foundation upon which they built their intelligence. They're just so bright. It also appears that they also have enough wisdom not to toss the oldsters out, because in many cases, they know that they don't have the experience. They ask the oldsters to be on advisory committees to help them, you know. But they're still the bright leaders. They recognize that the wisdom they lack is in some of the oldsters, and so they ask us for advice from time to time, to be on advisory committees and so on, and they seem to listen. That's good.

INTERVIEWER: That is good.

RADM MOONEY: I forget the date, but it was just before I got out of the Navy. I was asked to speak at a *Squalus* reunion. I went to Portsmouth and spoke to the assembled *Squalus* survivors. I think I've told you this story, but I'll redo it. I really wanted to recognize the divers who made the dives on the *Squalus*, and I didn't know that they were there, so I talked about the divers and what they did, saving lives and so on. The guys from the *Squalus* started smiling. When the thing was over, Captain Naquin, who was dead the year after, came up to me and said. "I'd like to have you meet these folks," and he had three of those divers there. They were the same family. They had become that over the years. He introduced me to three of those guys, two of who got the Congressional Medal of Honor, I think. I know one of them did. Naquin said, "Those guys you were talking about are right here. They're part of our crew." He introduced me to the divers. It was important to me, because I saw the *Squalus* when I was a kid, and I told them about that. The next year, Naquin was gone.

INTERVIEWER: Since this symposium, there have been four people who died. It was very fortunate that we had the symposium when we did.

RADM MOONEY: If you talk about the *Thresher*, most of the people with whom I've talked have never heard of it. They were born after it, you know. We tend to forget, with all the time that has passed and so on. But my kids remember it. I know that.

INTERVIEWER: I know with my students, when I talk about the *Squalus*, sometimes I'll see some blank looks on their faces. They have never heard about the *Squalus* and what happened. I think it's good to preserve these stories and retell them.

RADM MOONEY: Oh, yes. There was an O-9 in there, too, that I remember as a kid. I can't tell you what date it was roughly, but I remember it. It was almost 25 years from when I first saw the *Squalus* stick its nose up, and 25 years later, I was out looking for the *Thresher*.

INTERVIEWER: You mentioned you were on the *Tang*, as well. Did you talk with Clay Decker at the symposium a few years ago?

RADM MOONEY: No.

INTERVIEWER: Clay died a few months ago.

RADM MOONEY: Oh, did he?

INTERVIEWER: I guess he was the last surviving member who made the ascent.

RADM MOONEY: Yes. That was the old *Tang*, wasn't it?

INTERVIEWER: Yes.

RADM MOONEY: I was in the new *Tang*, 563. There was a series. There was the *Tang*, the USS *Trigger*, the USS *Trout* and the USS *Wahoo* or whatever.

INTERVIEWER: The original *Tang* was sunk in World War II.

RADM MOONEY: That was the *Tang* that he was on.

(Whereupon, the INTERVIEW was concluded.)

SUBMERSIBLE BASTARDS  
UDT 2/4, Little Creek, 1947-50  
A Memoir

*I make no claim that this is a history of Underwater Demolition. It is, at best, a personal memoir, my recall of events as I experienced them while assigned to Underwater Demolition Team TWO at Little Creek, Virginia from April, 1947 until June, 1950. Midshipman School taught me that Navy officers should never keep journals or diaries and the lesson stuck. So, lacking all but a handful of old photographs and the "sea stories" exchanged with others over the years, I can draw only on what I remember.*

*Oh, I have plenty of memories; it is their organization -- or disorganization -- that is the problem. Events shift from place to place, from one submarine or APD to another; names and faces refuse to correlate; chronology won't let itself be fixed either in reliable sequence or to dates on a calendar. This is probably true of a lot of autobiographical writing. Under the best of circumstances, memory becomes unreliable as we twist events, circumstances, participants to fit what we want to believe. Add to that the porosity of time -- more than fifty years in this case -- and I am not sure of what is left of reliability. In the end, my criteria of reliability more often than not are: this is the way I remember it; it seems logical; it feels right.*

*So, why bother. I believe that the period between the end of World War II and the beginning of the Korean War was crucial to the development of what is now known as Navy Special Warfare because it was a period in which that development might well have halted. It was a period when the very life of UDT was threatened, when there were only some 2-300 UDT officers and men in the entire Navy, when many in the Navy questioned the need for unconventional characters running around in greens and sand shoes, when service in UDT imposed limits on career advancement, when material support was niggardly at best. There was no career path in Special Warfare then; the Bureau of Naval Personnel limited Regular Navy officers strictly to three years in UDT and enlisted men were handicapped in their advancement efforts by chances to gain shipboard experience in their rates. Perhaps an incident which probably occurred in the Fall of 1947 or early 1948 illustrates the tenor of the times for UDT. Rear Admiral Draper Kaufman, the "Father of UDT" paid a visit to Little Creek. Rip Talent and I accompanied the Admiral to the O-Club for a hamburger and beer that noon. During our lunch, Rip asked the Admiral what his career advice he had for UDT officers. The Admiral's response was prompt and short: "Get out of UDT." (The difficulties of the period are accurately and vividly described by Don B. Belcher in "Dedication I" of his book, Fifties Frogs, Journal of the Underwater Demolition Teams.) UDT officers and men from both the East and West Coast*

*teams hung on, though, so that the legacy from the Naval Combat Demolition Units of World War II to present day SEALs remains unbroken.*

*The period is also important because it marked the submergence of UDT, the development of a capability to remain underwater for more than the span of a man's breath, the capability to operate from submerged submarines. LCDR F.D. Fane, commanding the UDTs at Little Creek recognized that UDT had to go truly underwater, that the conventional beach reconnaissance/obstacle clearance missions of UDT had to be expanded if UDT was to survive. At Little Creek, what became known as the Submersible Operations Platoon (SUBOPS) came into being to pursue new techniques and tactics in underwater operations under Fane's direction and leadership. Fane didn't exercise his direction and leadership from behind a desk; he was there in the water with SUBOPS, usually going first. I was fortunate enough to be assigned to SUBOPS from its inception until I was ordered out of UDT. Consequently, the focus of this memoir is on SUBOPS and my experiences with the men of that unit. This focus, however, is not intended in any way to downgrade or detract from the accomplishments of all the other UDT officers and men, both on the East and West Coasts. While we "Submersible Bastards" were playing our games, the rest of the officers and men of UDTs 2 and 4 at Little Creek, of UDTs 1 and 3 at Coronado, California were working under the same difficult circumstances to keep alive in an unbroken tradition what has come to be known as Navy Special Warfare, exemplified today by the U.S. Navy SEALs.*

-----

In the Spring of 1947, I made my escape from an old AP on which I was the most junior officer by volunteering for Underwater Demolition. In April of that year, I reported for duty to UDT2 at Little Creek, Virginia as an officer trainee in the first postwar UDT training class. I was a Lieutenant (junior grade) at the time. (That class and several subsequent training classes remained unnumbered, a source of considerable confusion at reunions in later years, as old UDT types argued about who came first among postwar replacements.) LTJG Allen Jones, Jr. and ENS Richardson reported for training at the same time along with about 40 enlisted personnel.<sup>1</sup>

At the time I reported, LCDR F.D. Fane was Commanding Officer, UDT 2 and the senior UDT officer on the East Coast. (I don't believe that COMUDTLANT had been formalized yet.) LTJG "Ski" Wryczinski, a former Yeoman, was Executive Officer of UDT 2. LT (or LTJG, I'm not sure) "Hal" Iverson commanded UDT 4. Among the other wartime officers in the two teams at that time were LTJGs Carson R. "Rip" Tallent, Bill Mason and H.L. "Gary" Garren, Jr. Gary Garren was deployed to the Antarctic with Team 4 at the time. It was Garren, as CO, who had brought the newly designated UDT2 from Coronado, California to Little Creek, Virginia. Garren and Iverson not only had to beg for office, warehouse and barracks space from the commander of the Little Creek Base but also establish the UDTs as independent commands on the base. When a UDT man was put on report by a Base MAA for being out of uniform (wearing greens instead of dungarees,) Garren had to convince the base commander that he, not the base commander had punishment jurisdiction over the UDT man. Fortunately, Garren was able to produce a letter from the Navy's Judge Advocate General assigning punishment jurisdiction to the designated

---

<sup>1</sup> I will use rank or rate held at the time throughout this memoir.

COs of UDTs. Shortly thereafter, F.D. Fane arrived to assume command of UDT2 and UDTs, Atlantic Fleet. Upon Garren's return from the Antarctic and Ski Wryczinski's departure to civilian life, Garren became Executive Officer of UDT 2.

Even before I met Garren, I was in awe of this wartime officer who was off swimming around in Antarctic waters. But as soon as he returned, we discovered that we had received our commission in the same midshipman training class at Plattsburg, N.Y. We soon became the closest of friends and remained so until his death in 2000,

` If there was one officer who all of us trainees held in awe, it was Rip Tallent. He was the Training Officer for that first postwar class and he demonstrated to us from the outset that he wasn't to be toyed with. But we all respected him as a fine officer and, when we weren't doing pushups or sand-running, a friend.

We trainees stood in awe of the senior enlisted men of the teams perhaps even more than of the officers. After all, it was the enlisted instructors who ramrodded us through most of our activities, who stood over us shouting at us to get moving, who harassed us constantly and laughed when we moaned and groaned. Still, however much we felt put upon, we could never forget that both the officers and enlisted men who were pushing us had earned their qualifications during wartime and had experienced in combat that they were trying to teach us in peacetime. Among the combat-tested men who were our instructors were MRC "Al" Foster, GMC John "Andy" Devine, YNC Jack Riggart, GM1 Sam Bailey, GM1 Robert Winters, EN1 John Koerber, BM2 Joe DiMartino, GM2 Hugh Peddy, GM3 "Benny" Sulinski; many others, of course, but memory fails.

If that training is for me, now, a blur of fatigue, fear, fun and exhilaration, three events stand out in memory:

- The Mile Swim (without fins) required to qualify for fins. Rip Tallent had us far out in Chesapeake Bay for about three hours, swimming against the current while successive schools of stinging sea-nettles drifted over and around us. I can still see Rip standing in the bow of an LCPR shouting, "SWIM," when we complained about the sea nettles. As for the current, I don't think we covered much more than a quarter of a mile over the ground in the entire three hours before Rip finally decided that we had swum the "equivalent of a mile."

-Then, there was the day that ENS Richardson taped a 2lb. block of tetrytol against the web of a 90 lb. jetted-steel rail on Beach 7. Who could forget the look on Commander Fane's face as he picked up the telephone to croon "Helooo" when the Base Duty Officer called to complain that an eight-inch piece of heavy shrapnel had just penetrated the roof of COMPHIBTRALANT's quarters and ripped a chunk out of the mantelpiece over the admiral's fireplace.

- One day toward the end of training, the class moved across the Bay to Fisherman's Island for field exercises. That night, Gary Garren and Hal Iverson decided that it would be a good idea for some of us to go back across the Bay to infiltrate the Amphibious Base on a reconnaissance exercise. We made it into the base undetected -- no great feat in those days -

- and split up into pairs to cover assigned targets. BM3 Frank Kappesser and I spent a couple of hours lying in a tulip bed outside the OOD shack at the Main Gate, making notes on everything that went on and all that a sleepy security crew said. There is a story, quite often repeated at reunions, that a sentry came out to relieve himself on me while I remained motionless and undetected. I remember vaguely a sentry coming out and relieving himself in close proximity but, perhaps due to some phenomenon of psychological denial, don't remember getting hit.

But the coup of that night was the pair (names unrecalled) who made their way into the quarters of COMPHIBTRALANT and are reputed to have chalked, "UDT was here" on the foot of the bed occupied by the admiral and his wife. COMPHIBTRALANT did have his problems with us.

It is, perhaps understandable that in the conventional Navy of that pre-USS COLE, pre-9/11 era, substantial segments of the Navy's hierarchy considered UDT as undisciplined trouble-makers who had no legitimate function in future naval warfare but the Navy was to learn better..

With training completed in June, 1947 and UDT qualification in their records, the members of that first postwar training class settled down to become full-fledged members of UDTs 2 and 4. Al Jones and Richardson were assigned to UDT 4; I landed in UDT 2. We were soon to learn that, despite so many questions about the Navy's need for UDTs, incessant demands for our services would deny us many uninterrupted periods at Little Creek.

In the Fall of 1947, Bill Mason led a small detachment to Panama City, Florida to survey beaches in the vicinity of Tyndall Air Force Base in advance of a scheduled amphibious landing exercise there. I was sent along to be Mason's Asst. O-in-C and to gain some experience. Somewhat in awe of having "Frogmen" in their midst, the base personnel treated us royalty and miles of wide, almost deserted beaches made the deployment more pleasure than work. That is until, one Sunday morning, Mason and I ran into what apparently was the so-called "Red Tide." By the next morning, both of us felt like we were near death from influenza. We turned into the Air Force Dispensary where the doctor diagnosed us as being hung over from too long at the O Club. and issued us some APC pills. But the worst symptoms disappeared in a few hours although I looked as if I had a good case of measles and itched miserably for several more days. Despite that, we finished the survey work on time. That deployment yielded an unexpected opportunity for Mason and myself. On one of our last nights at Tyndall, a Saturday, Bill and I were having a few drinks at the O Club. An Air Force major in uniform was especially attentive to us. After he bought us several drinks, he revealed that he really was a reserve officer. After a couple more drinks, he further revealed that he was a recruiter for the Zionist Irgun and said that he was very interested in our demolition skills. While nothing very specific was said, the major implied that we could make a good deal of money with the Irgun. We, however, decided that we weren't interested in any such adventure.

Soon after Mason's detachment returned to Little Creek, UDT 2 embarked on an APD (probably USS CARPELLOTTI) for an amphibious demonstration at Miami Beach, followed by a large-scale amphibious exercise on the beaches we had surveyed. The landing exercises were followed by ship visits to New Orleans and Galveston with several days of liberty in each place. Life in UDT seemed pretty good to us recent trainees.

Sometime during that period, LCDR Fane directed me to take a small detachment of men from both teams to Naval Air Station, Jacksonville, Florida. We were to conduct a demonstration in the Air Station swimming pool during the All-Navy Swimming Meet being held there. Sam Bailey, Joe DiMartino and Benny Sulinski were among the men in the detachment. As often in such cases, we gathered together whatever gear we thought might be useful and would come up with a specific demonstration script once on site. Now, there was an old Jack Browne lung which had been in the team warehouse since the teams moved East and wasn't highly regarded. But, Fane had recently acquired a dozen or so Lambertsen Amphibious Respiratory Units (LARUs or Lambertsen Lungs) from an Army/Navy surplus store. LARUs had been used by the OSS Maritime Unit during WWII operations in SE Asia. UDT had been equipped with some LARUs during WW II but their use had apparently been limited to a few scanty indoctrination dives. In any event, no one at Little Creek knew much about the capabilities, limitations or proper use of either the Jack Browne or the Lambertsen units. There was, however, under the impetus of Doug Fane's thinking about the future of UDT, increasing interest in developing a true underwater capability for UDT. So, we included the Jack Browne and a Lambertsen unit in the gear for Jacksonville, thinking we might be able to use them in the Olympic-size swimming pool. Once in Jacksonville, I think it was Benny Sulinski who took the LARU down for a dive in the pool with, as I recall, the oxygen bottle filled with compressed air! . Fortunately, Sulinski swam only one length of the pool before we decided that there was no drama in someone swimming underwater, almost unseen, so we dropped use of the lungs from consideration. We put together a pretty good show without the lungs and the audience loved it. Base authorities were less enthusiastic when they discovered that the explosive charges we used had cracked half of the pool's underwater lights. Those charges were small: a nonelectric blasting cap with about two inches of detonating cord attached. But after assembling the charges, Sam Bailey had some eight inches of detonating cord left over. So, to avoid carrying it back to Little Creek, he simply taped it to one of the charges. That almost brought the house down -- literally.

LCDR Fane had recognized shortly after the end of World War II that the "Underwater" in Underwater Demolition Teams was a misnomer since virtually all operations were conducted on or very near the surface and, in the latter case, only for the duration of a man's held breath. If UDT was to survive and progress, a true underwater capability had to be developed. Fane learned that Dr. Lambertsen was training Army personnel in the use of the LARU at Ft. Knox, Kentucky. Lambertsen had originally developed the LARU while a medical student at the University of Pennsylvania. Unable to interest the U.S. Navy in his apparatus in the early days of World War II, he had attracted the interest of OSS. He joined OSS himself and trained personnel of the OSS Maritime Unit in underwater operations as well as participating in such operations in Southeast Asia himself. In January, 1948, Fane brought Lambertsen to Little Creek where he spent several days indoctrinating selected personnel in the use and maintenance of the LARU

This indoctrination was essential if UDT men were to start using the LARU. Without such training, use of a breathing apparatus such as the LARU would be extremely dangerous. The LARU was a closed-system, recirculating, oxygen-breathing apparatus. Pure oxygen, admitted to a breathing bag from a small, pressurized, supply bottle, passed through a hose and one-way valve to a full-face mask from which the swimmer inhaled oxygen. Exhaled breath passed through another one-way valve and hose to a canister mounted behind the swimmer's

neck and filled with Baralyme (soda-lime) which absorbed the carbon dioxide. After passing through the carbon dioxide absorption canister, theoretically clean oxygen was returned to the breathing bag. A valve controlling the flow of oxygen from the supply bottle allowed the swimmer to replenish the oxygen in his breathing bag as it became depleted. Theoretically, such a system was highly efficient. Because pure oxygen was provided (the air we breathe is only about 20% oxygen) and was stored in the supply bottle at an initial pressure of about 1,800 psi., an ample supply of oxygen could be carried in a relatively small bottle. Since the system was closed, the swimmer left behind no stream of bubbles by which he could be detected. But there were several dangers. If all air was not removed from the breathing bag at the outset, the swimmer could deplete his oxygen supply while still inflating his lungs with odorless, useless nitrogen and thereby succumb to anoxia. Further, even with a LARU in perfect condition and fresh soda-lime in the canister, carbon dioxide absorption was less than 100%. As the Baralyme became exhausted or the canister leaked even slightly, carbon dioxide absorption was further degraded and the swimmer would breathe high levels of carbon dioxide causing headache, disorientation, ultimately death. Fortunately carbon dioxide intoxication is quite uncomfortable and the trained swimmer would recognize it at an early stage. Oxygen toxicity was a more insidious hazard. Pure oxygen breathed under greater than atmospheric pressure is toxic. Depending on the depth at which he is working, the amount of exertion, the presence of carbon dioxide traces, and his own inherent susceptibility, the swimmer on pure oxygen will sooner or later experience euphoria, muscle spasms, then a full-scale epileptiform convulsion which renders him totally helpless and leads shortly to death. The progression of these symptoms after onset is very rapid; once onset is detected, unless the swimmer is experienced and lucky, his recognition of what is happening to him will come too late.

Fane had also recognized that most of the advantage of a true underwater capability would be lost if swimmers had to be transported to their target areas on surface ships or in submarines required to surface to launch their swimmers. Ideally, an underwater mission would be conducted entirely submerged: from port-to-target-to port. With this in mind, he had contacted Commander, Submarine Squadron TWO and laid the groundwork (awkward term in this context but, then, CO UDT 2 once received a letter from Army Engineers addressed to “Underground Demolition Team TWO”) for attempts to launch swimmers from submerged submarines utilizing the submarines’ escape trunks.

With such future operations in mind, Fane led a detachment of UDT officers and men to the U.S. Navy Submarine Base at Groton, Connecticut. Among those making the trip in addition to Fane were Garren, Tallent, Mason, Jones, Foster, Devine, Kappesser and myself from UDT 2. Koerber, Sulinski and DiMartino may have represented UDT 4 and others were certainly involved. Submarine Base personnel instructed and qualified the UDT officers and men in locking out of a submarine escape trunk as well as in free ascent (without breathing apparatuses) from the 100’ lock in the Submarine Escape Training Tower. Additionally, all the UDT men underwent oxygen toxicity susceptibility testing, breathing pure oxygen in a recompression chamber pressurized to the 60 foot level for up to 30 minutes. I introduced the UDT contingent to the spectacle of oxygen poisoning by promptly throwing a classic convulsion. Several others followed shortly thereafter. Legend has it that the sight of wildly thrashing, frothing UDT men being hauled out of the building on stretchers caused a number of submarine trainees waiting nearby for their turns at escape training to defect from submarine training.

This visit to New London by the UDT detachment accomplished far more than the training and experience which accrued to the UDT men. A solid relationship between UDT and Submarine Force, U.S. Atlantic Fleet was established. This was important in more ways than one. If UDT was to expand its underwater capabilities on any meaningful basis, Fane had to attack very real problems: not only those of submerged transport but of getting equipment and learning to use it, of selecting personnel who were psychologically and physically suited for underwater operations, and of gaining Navy institutional support for efforts which were to many senior officers of the surface Navy beyond the conventional missions, missions which they often supported only reluctantly in the first place. The solutions to several of those problems converged rather neatly in the relationship with SUBLANT. The advantage of submarines as transport vehicle has already been mentioned. Moreover, submariners who traditionally held themselves relatively independent of the surface Navy were quicker to understand and support experimentation with new underwater techniques and tactics. Perhaps most importantly, submarine medical officers were not only quite familiar with such effects as oxygen toxicity, carbon dioxide intoxication and other diving hazards but the Submarine Medical Research Laboratory under Captain Willmon was already conducting active research into the etiology of oxygen toxicity utilizing the service of an expatriated German physiologist, Dr. Schaefer. For their part, the UDT men provided Dr. Willmon's laboratory with a ready pool of research subjects. The UDT men also realized that free ascent training in the 100' tower offered a unique opportunity for psychological and physical screening of candidates as well as for increasing self-confidence in underwater environments for those candidates found suitable for further training. At least one subsequent Replacement Training Class went to New London in its entirety for tower screening. One additional element in the UDT/SUBLANT relationship was to prove crucial in the next few years. Vice Admiral Fife, Commander, Submarine Force, U.S. Atlantic Fleet was enthusiastic in his support of the UDT efforts and of UDT/SUBLANT cooperation.

With selected personnel trained in the use of the Lambertsen units and the New London exercises completed, the stage was set for actual UDT/submarine operations. In February, 1948, UDTs 2 and 4 embarked in APDs for conventional reconnaissance and demolition operations at a beach on Vieques Island during the amphibious phase of Atlantic Fleet's winter fleet exercises. (It was probably during this cycle of exercises that a small detachment of UDT men penetrated beach defenses a day or two before D-Day, "obtained" some USMC fatigue uniforms and a jeep and spent several days harassing the defending forces in the hinterland. One UDT man, posing as a Marine courier, presented U.S. Marine Corps Lieutenant General Keller M. Rockey with a package containing a booby-trapped hand grenade which, if it had been real, would undoubtedly have killed the general and several of his staff. General Rockey, too, became a strong supporter of UDT. Among other things, at a subsequent reception in Port Au Prince, Haiti, the General startled several UDT officers by greeting each of them by name.)

Following participation in the fleet exercises, the officers and men who had been through the New London indoctrination rendezvoused at St. Thomas with the submarine, USS GROPER commanded by CDR Charles F. Putnam<sup>2</sup>. Dr. Lambertsen joined Fane, Garren,

---

<sup>2</sup>In describing these early swimmer/submarine operations, I have bolstered and corrected my memory by reference to the well-documented account in John B. Dwyer, Commandos From The Sea, Boulder Colorado: Paladin Press, 1998, pp. 116-124. See also, Francis Douglas Fane and Don Moore, Naked Warriors, New York: Appleton-

Jones, Foster, Devine, Bailey, Kappesser, Piotrowski, Petway and myself, among others, for operations from GROUPER in Pillsbury Sound. between St. Thomas and St. Johns. The objective of the UDT/GROUPER operations at this time was to test the feasibility of launching and recovering UDT swimmers from a submerged submarine. On February 20, 1948, GROUPER bottomed in 54 feet of water. to attempt to launch and recover swimmers via the escape trunk. Because of the bulkiness of the LARUs and the necessary presence of an escape trunk operator from the submarine's crew, only two swimmers at a time could occupy the cramped, cylindrical escape trunk, Fane and Lambertsen were the first to exit the submarine and swim to the surface after which they swam back down and reentered the submarine. The other UDT men followed in pairs, with each pair making two exits and recoveries that day. The ability to operate from a bottomed submarine had been proved and soon became routine.

The next step was to test the capability of leaving and reentering a submerged, underway submarine. On February 22, 1948, Fane and Lambertsen again led the way, locking out of the underway GROUPER, then returning. Again, the other swimmers followed. Although the speed of the submarine was usually held to bare steerage -- and depth control -- way, about two knots, the speed of the submarine increased to six knots on at least one occasion when the diving officer began to lose depth control. Despite a battering from the six-knot, over-deck current, the swimmers were able to hang on although the effort created an immediate danger of exhaustion or, worse, oxygen poisoning. Still, these exercises proved the feasibility of delivering and retrieving combat swimmers by submerged submarines and gave the UDT swimmers a high degree of confidence in their ability to operate successfully from submarines.

Upon completion of the St. Thomas exercises with GROUPER, Fane and his officers and men knew that they were truly in the underwater business. It was apparent, however, that the limited availability of equipment as well as the need for selecting personnel carefully would require concentration of effort if the development of underwater operations were to proceed in a highly focused manner. While returning from those operations aboard an APD, I wrote a memorandum to COMUDTLANT proposing that a separate platoon be established and manned with personnel selected from both Teams 2 and 4 to specialize in future underwater development. I have no idea as to whether or not that memorandum influenced the decision -- very likely, Fane had already planned such a step -- but, shortly after return to Little Creek, COMUDTLANT formally established the Submersible Operations Platoon, or SUBOPS as it came to be known. I was fortunate to be assigned as Platoon Officer, with LTJG Al Jones as Assistant Platoon Officer. Among the enlisted personnel who made up the initial complement of SUBOPS or who were to join it shortly after with the selection of some men from the 2nd and 3rd replacement Training Classes of 1948 were MRC Al Foster, GMC Andy Devine, GM1 Sam Bailey, GM1 H.L. Piotrowski, DC1 Wilson Bane, BM3 Frank E. Kappesser, Frank Hale, GM3 J.J. Petway, BM2 Roy O Rollins, QM3 Ronald LeMay, GM2 Henry Spiegel, TM3 John P. O'Brien, GM2 Chester C. Stevens, BM3 Glen Baker, BM2 Joseph DiMartino, GM3 Benny Sulinski, QM3 James Cook, Thomas McAllister, BM3 George Phipps, BM2 William C.

---

Century-Crofts, Inc., 1956, pp.277-302 for a vivid and more detailed description of early UDT/submarine operations in the Caribbean. There is some conflict between sources regarding command of USS GROUPER during these February, 1948 operations. My memory as well as Commander Fane's book cite Commander Miles Refo as CO, GROUPER. Dwyer, relying on GROUPER's patrol reports for the period, cites Commander Putnam as CO, GROUPER.

Hollingsworth, DC3 Harold L. Crowell, and “Robbie” Robinson. (George Phipps was killed in action in Vietnam years later. Thomas Mc Allister died in an accident during operations near St. Thomas. Joe DiMartino, later an early SEAL officer, was once dubbed one of “America’s Ten Most Dangerous Men” by TRUE Magazine. I believe that several of these men subsequently earned commissions and several were among the first SEALs.)

SUBOPS was established as an entity within UDTs 2 and 4. But there seemed to be a danger that its identity could easily be lost in the routine daily activities of the teams. There was also a need for work space as well as for separate and secure storage for the LARUs and supporting equipment such as bulk oxygen bottles, a compressor, a variety of tools and so on. Another consideration was classification security. By the very nature of their work, combat swimmers require secrecy. While there was a need to advertise UDTs accomplishments in going underwater in order to gain higher level support, it seemed advisable to most of the SUBOPS men that the general population, Navy and civilian, not be afforded free access to what we were doing. SUBOPS clearly needed a “home” of its own, separate from the regular UDT warehouses and offices at Little Creek.

It happened that there was an unused, concrete block brig surrounded by a barbed wire topped, eight-foot, chain-link fence with a lockable gate immediately behind the UDT 2 and 4 warehouses. Although it was partly subdivided by steel-barred confinement cells, several of them filled with rusting bunk frames and rotting mattresses, the brig offered the advantages of a spacious office, a large room suitable for a workshop, toilet facilities and a number of empty cells useable for storage or small work spaces. The idea of taking over that old brig was broached and Fane began applying his persuasive powers to the Amphibious Base hierarchy. After continued urging and somewhat inflated claims as to the security classification of SUBOPS activities and equipment, Commander, NAVPHIBASE LCREEK granted permission for SUBOPS to occupy the brig provided that nothing be disturbed and that the building be available for return to the base within 24 hours.. We moved into The Brig promptly and, within a couple of weeks had it cleaned out, painted and converted -- permanently -- to our own uses. All of the decaying detritus of earlier use were stuffed into a couple of the back cells and forgotten. WE put a heavy, secure lock on the gate and posted “RESTRICTED AREA -- AUTHORIZED PERSONNEL ONLY” signs on all four sides of the fence. The fence and gate were especially valuable in protecting SUBOPS from kibitzing by non-UDT personnel of all ranks as well as casting a protective cloak of mystery over what we were doing. No doubt, certain empire-building proclivities were also satisfied. In any event, The Brig, as it became known, was to play a significant role in furthering UDT’s underwater aspirations for a number of years.

Some of the SUBOPS men were eager to increase their technical training in underwater operations by qualifying as deep-sea, “hard hat” divers. It was clearly to UDT’s advantage to have such expertise available within the teams. Accordingly, Chiefs Foster and Devine, both already qualified as Salvage Divers, were sent to First Class Diving School. Later, in August, 1949, Kappesser and McAllister went to Second Class Diving School at Portsmouth, Virginia. They were followed shortly after that by Phipps and Hale. R.O. Rollins was already a Second Class Diver when he joined UDT. (After leaving the Navy, Hale made a second career in deep-sea diving, serving as a Diving Supervisor for several years during the construction of well platforms in the North Sea oil field.)

It was at about this time that UDTLANT lost two more of its most experienced officers. Hal Iverson and Bill Mason had already left. Now, Rip Tallent and Gary Garren were ordered to shipboard duty. This loss of experienced officers was to plague UDT for a number of years. At that time, there was no career path in special operations for officers of the Regular Navy. While Naval Reserve officers could remain in UDT for more extended periods, young, Regular Navy officers were permitted only three year tours of duty in UDT.<sup>3</sup> While the enlisted men were not subject to a specific duration of duty in UDT, they clearly suffered career disadvantages. Except when embarked on ships for transit, they had little chance to expand and hone their expertise in their respective occupational specialties. In preparing for fleetwide advancement examinations, the men had to rely on their own perseverance in studying and their initiative in taking advantage of scattered opportunities to gain experience aboard ship. It is a tribute to the quality of the men who volunteered for UDT that so many were successful in successive fleetwide examinations and achieved the highest levels in their respective rates.

Even back in the early days of SUBOPS, UDT men were thinking about expanded missions. LCDR Fane, of course, had already taken UDT truly underwater and established the viability of UDT/submarine operations. In early 1947, Fane had proposed the development of a ship assault capability to the Amphibious Type Conference. Back in The Brig, we talked about what missions beyond conventional beach reconnaissance and obstacle clearance we might perform. At one point, LTJG Garren and I drafted a letter proposing that the evolving underwater capabilities be exploited for their application to such missions as ship assault, as well as hinterland penetration for reconnaissance and intelligence collection, sabotage and commando-style raids. We also discussed the potential of air delivery to supplement submarine transport. I have no idea of what happened to that letter except that it obviously didn't get very far. Still, such ideas were not viewed with any enthusiasm by the mainstream Navy. Despite the valuable contributions of NCDUs, Scouts and Raiders and UDTs during World War II or the feats of British and Italian underwater operators, few in the Navy seemed to consider unconventional operations appropriate in the nuclear age. Reactions to a ship assault exercise at Argentia, Newfoundland, to be described shortly, confirmed to us the widespread disdain for such "games."

Doug Fane, however, was persistent.. He continued to evangelize the conventional Navy at all levels as to the need for expanded support for underwater operations as well as to scour the country for useful equipment. He located two crated British submersible boats in a west coast warehouse and had them shipped to Little Creek. Dubbed "Sleeping Beauties" by the British, these boats, with hulls of sheet steel, were each 12'8" in length, each with a single, open cockpit. A Sleeping Beauty was powered by an electric motor and an automobile-type storage battery located in a watertight compartment just forward of the cockpit. Two ballast tanks, one on each side of the operator's legs, as well as a small trim tank in the bow of the boat provided depth and trim control. Kingston valves in the cockpit and an air-pressure system permitted flooding and blowing of the tanks. A rudder provided lateral control of the boat while diving

---

<sup>3</sup>When, in June 1950, I received orders for duty in a heavy cruiser, I called the LTJG Detailer at BUPERS and begged for a one-year extension in UDT. His refusal was accompanied by the blunt comment, "The place for a young officer of the Regular Navy is on the bridge of a combatant ship."

planes, one on each side of the stern, allowed attitudinal control while running submerged. Instrumentation consisted of a wind-up clock, a magnetic compass and an air pressure gage. If I recall correctly, a Sleeping Beauty was capable of a maximum surface speed of 5 knots and maximum depth of 50 feet. The operator of an SB, sitting in the open cockpit, had of course to wear a breathing apparatus. The only protection he had from the sea was a heavy canvas skirt, secured around the coaming of the cockpit, which he could zip up around his neck. SUBOPS personnel promptly shortened "Sleeping Beauty" to "SB", from which other UDT personnel derived SUBOPS' alternate sobriquet: "Submersible Bastards."

The SBs were painted a dull, wartime gray when we received them. The SUBOPS men promptly repainted them with Navy-issue "yellow striping" for safety reasons and hauled them down to the Little Creek beaches to try to figure out how to use them, with little success. Dr. Lambertsen again came to the rescue. He had operated SBs for OSS in Southeast Asia and quickly taught the SUBOPS men how to operate the boats. However, it was apparent that, after long storage, the boats were not in very good condition. The battery compartments leaked because of dried gaskets, electrical insulation was in poor condition and a number of screws and screw sockets were rusted or missing. There were no spare parts available and American substitutes could not be used because all the fittings were to British specifications. Fane arranged for Chiefs Devine and Foster and several more SUBOPS men along with me to take the SBs to New London where we were to overhaul the boats with the assistance of SUBLANT technicians. I think that the submariners at New London were both amused and fascinated by the idea of working on these "tin underwater canoes." Again, SUBLANT cooperation was unstinting. The electric motors were overhauled in Submarine Base shops, New London provided tools and material so that the SUBOPS men, under Foster's supervision, could drill and retap all screw fittings to American specifications. New batteries were obtained. Finding suitable material to make the battery compartments watertight proved to be a problem. One of the base shops came up with suitable neoprene gasket material and cut new gaskets to precise dimensions. The battery compartment of an SB was fitted with a small, cylindrical relief valve intended to relieve any buildup of battery gas. Its functioning required a rubber sleeve which would fit tightly enough to prevent any water from getting in and yet stretchable enough to permit battery gas to escape. That stumped us for a while until the Base Dispensary came up with rubber surgical tubing which worked perfectly. Finally, the Submarine Base made the Base Swimming Pool available for shallow water testing of the boats. To be completely watertight, the neoprene gaskets for the cover plate of the battery compartment required some sort of sealant. SUBOPS men tried everything from red and white lead to commercial roofing compound. Finally, an asphalt-based compound proved useable. By the time the problem was solved, however, the swimming pool was decorated rather liberally with red, white and black smears which the SUBOPS men worked on for hours but never eliminated entirely. If that swimming pool at new London still exists, perhaps some of those stains remain as a memorial to SUBLANT/UDT cooperation.

I have already alluded more than once to the lack of support perceived by UDT officers and men. Many of us, in fact, felt that UDT was hanging on to its existence by its fingernails. As is frequently the case for elite units within the military, UDT was viewed by a good number of Navy officers with suspicion and a certain amount of resentment. Some argued that, in the nuclear age when wars would be fought at long range with advanced weapons, UDT was an archaic holdover from World War II and should be eliminated. The large majority of those who

ever thought about it were willing, of course, to tolerate UDT so long as UDT men behaved, didn't become too presumptuous and didn't pose any excessive drain on Navy resources. (Our licit drain on Navy resources certainly was minimal; our illicit drain was probably more substantial.) There were some senior officers -- Admiral Fife, Admiral Barbey and General Rockey for example -- who recognized the potential and supported efforts to move ahead. But it was often rough going for the UDT men on both coasts as they tried to carry out what they saw as their appropriate roles with extremely limited and often obsolete resources. LCDR Fane recognized clearly that, despite some legitimate requirements for classification security of UDT operations and developments, attracting the attention of influential elements of the Navy and convincing them of the need for properly trained and equipped underwater units were vital.

Thus, the stay of the SUBOPS detachment at New London to overhaul the SBs was interrupted by an order to proceed with one boat to the Naval War College at Newport, Rhode Island where Fane was to address the officer students. We drew a truck from the base Base Motor Pool, loaded one SB on its wheeled dolly onto the truck and shrouded it with canvas. Motivated more by theatrical interests than by any perceived threat to national security, I drew a sidearm from the Base Armory. Two of us -- it may have been George Kudravitz who drove the truck -- took off for Newport. We arrived just in time for Fane's presentation before several hundred Navy officers among whom were a good many future admirals. I just had time to strip down to swim trunks, put on a LARU and get pushed out onto the stage sitting in the cockpit of the SB. If the presentation impressed the assembled audience-- and it clearly did -- it was due to Fane's rhetorical skill because I couldn't do a thing except sit there, occasionally wiggling the rudder and diving planes at what I thought were appropriate times. The sidearm I carried did come in handy during our drive back to New London. Kudravitz got hung up in a traffic jam at a busy intersection. I was in uniform, had that side arm in a polished holster strapped around my waist and that heavily-shrouded shape on the flat bed lent an air of mystery to the truck. I stepped out into the intersection and stopped traffic in all four directions while Kudravitz drove on through, laughing his head off. Perhaps we did get a bit presumptuous at times.

In October, 1948, Fane, a detachment from SUBOPS and a heavy load of equipment including one SB were flown to St. Thomas to rendezvous with USS QUILLBACK (SS424) commanded by LCDR C.R. Clark. Joining the UDT detachment were Dr. Chris Lambertsen, LCDR E.R. F. Johnson, USNR, A.C. "Al" Dyer (Johnson's assistant and technician,) a Lieutenant Colonel from U.S. Army Engineers (name unrecalled,) William Fields (a civilian engineer from the Bureau of Ships,) and a Navy Chief Photographer's Mate (name unrecalled.) In addition to Fane, the SUBOPS detachment consisted of Ensign George Atcheson (on TAD from the West Coast teams,) Chiefs Devine and Foster, Sam Bailey, Henry Piotrowski, Frank Kappesser, George Kudravitz, A.B. Henderson, J.J. Petway and myself.

E.R.F. Johnson was an experienced diver and a pioneer in the development of underwater photography, Cameras, both motion picture and still, designed and built by Johnson and Dyer were among the first to be used successfully to produce high-quality, underwater photographs. Intensely interested in what Fane and his SUBOPS crew were attempting, Johnson volunteered his and Dyer's services at Johnson's own expense. With their expertise and equipment, the operations

from QUILLBACK could be documented with dramatic photography. Moreover, both Johnson and Dyer as well as Chris Lambertsen became, as far as the SUBOPS men were concerned, integral and highly respected members of their close-knit team. Although considerably older, Johnson could outswim most of us and Chris Lambertsen became and remained our mentor in the truest sense of that term.

A major objective of the operations with QUILLBACK was to develop techniques for operating small submersibles from a full-scale mother submarine. At the outset, Lambertsen had the opportunity for the first time to train and qualify SUBOPS SB operators in water of more than a few feet in depth. Under Lambertsen's guidance, all of the SUBOPS men quickly became qualified SB operators. The next step was to experiment with taking the SB off the deck of the bottomed submarine and landing it again. This, too, was accomplished rather quickly. The logical extension of these operations, of infinitely greater tactical significance, was developing the capability of taking off from and landing on the deck of a submarine while it was underway submerged. The SUBOPS men had already learned to handle themselves on the deck of a submerged, underway submarine during the GROUPER operations. But, could the SB take off and land and could the SUBOPS deck crew handle the boat on deck?

A serious problem was that the parent submarine could not operate submerged at less than two knots and the SB's maximum submerged speed was little more than that. Taking off should be easy: the SB operator could simply gain some buoyancy and let the submarine go out from under him. But there was little margin of speed to allow the operator to maneuver onto the deck while landing. Lambertsen came up with the idea of streaming a length of 21-thread line with a buoy at one end and the other end secured to the bull nose of the submarine. The idea was that the SB operator would intercept and latch onto the buoy being towed by the submarine, cut the motor so that the SB was towed by the submarine, gain negative buoyancy and settle on to the deck. It seemed a dicey sort of operation at first and Chris Lambertsen, because of his superior skill and experience in the SB, made the first attempts. E.R.F. Johnson and Fane were on deck to photograph the operation; Atcheson, Bailey and Piotrowski, all big and strong men, constituted the recovery crew who would help guide the SB onto the submarine's deck and secure it there. As described by Johnson, quoted in Fane and Moore, *op. cit.*, the overdeck current as well as choppy surface conditions whose effects could still be felt 30 or 40 feet underwater, made the recovery extremely difficult. The operation required exceptional skill and endurance on the part of the recovery crew.<sup>4</sup> Still, Lambertsen proved that the launch of a Sleeping Beauty from the deck of a submerged, underway submarine as well as recovery of the SB were entirely feasible. I soon got my chance and had no great trouble executing the maneuvers. Soon, a number of the men had become quite adept at the maneuvers..

While the initial launches and recoveries were made on the foredeck of the submarine we must have at some point moved SB operations to the afterdeck of the submarine. I'm sure that most of my launches and recoveries were made aft of the submarine's sail. One end of a towline was secured to the after side of the submarine's conning tower with the buoyed loop at the other end.. As it turned out by trial and error, the best tactic was for the SB to approach on the surface but partially trimmed down (i.e., with its deck awash) on a course roughly perpendicular to that

---

<sup>4</sup> At this time, there was no shelter for the SB on the deck of its parent submarine. The SB, when on deck, was secured in its wheeled dolly which, in turn, was lashed to the deck of the submarine.

of the submarine from a point off the bow of the submarine. The SB operator had to judge his course and speed to reach a position over the submarine's deck just aft of the conning tower as it passed. The SB operator would reach out, pass a short length of line secured to the bow of the SB through the bight of the towline, cut the motor so that the SB was then being towed by the submarine, then flood the ballast tanks to gain negative buoyancy and settle down into the hands of the waiting SUBOPS recovery crew. Initially, there was a minor problem for the operator in getting a purchase on the bight at the streamed end of the towline. One of the Chiefs quickly came up with the idea of fabricating a steel hook, perhaps a foot long, from a piece of reinforcing rod.. With this secured to the short length of line secured to the bow of the SB, the operator could easily reach out to snare the bight of the towline. That worked like a charm.

All of this was, of course, recorded on film by Johnson and Dyer. But Johnson wasn't satisfied with simply filming these operations from a standoff position. He soon conceived the idea of mounting his motion picture camera on the SB. Foster, Devine and Dyer devised a suitable mount for the large, waterproof "blimp" which encased Johnson's 16 mm. movie camera. The mount was placed between the forward edge of the cockpit and the after edge of the battery compartment. Normally, to run submerged with proper control of the boat's longitudinal attitude, the SB operator had to let water into the trim tank in the bow of the boat. Fortuitously, the weight of Johnson's camera blimp, placed where it was, almost exactly compensated for the weight of the water normally admitted to the trim tank to trim the boat. Of course,, you had to aim the boat to aim the movie camera but the pilot could start and stop the camera simply by reaching up a few inches to activate a trigger on the side of the camera blimp. Another of Johnson's cameras was a 35 mm. still camera encased in a cubical, waterproof case about 8"x8"x8", with a pistol grip fitted to the bottom. It was awkward for the pilot to carry this camera in his lap in the cramped cockpit so the men cut a square hole and constructed a well just aft of the cockpit of one of the boats. With the still camera stowed in the well with the grip sticking up, the pilot had only to reach over his shoulder to pull the camera out.

The SB operators were soon taking still and motion pictures of anything and everything: the parent submarine, coral heads, schools of fish, and barracuda (which seemed fascinated by the bright yellow shape and would swim alongside the SB eyeing it suspiciously with their huge eyes.) I recall filming footage of the slowly turning screws of QUILLBACK from directly astern as well as footage of the submarine's JT sound head tracking the SB. What I am sure was footage obtained by SUBOPS men with Johnson's camera showed up in several Hollywood movies in later years, presumably obtained by Hollywood directors from the U.S. Navy Photographic Center at Anacostia, D.C. The SB operators also like to dive bomb the submarine's sonar heads. I once incurred the wrath of a QUILLBACK Sonarman by slapping the steel hull of the SB with a wrench just as I guided the SB close to the JT sonar head.

The limited capacity of a submarine's escape trunk became a source of concern as future tactical operations were considered. It took a number of minutes to put each pair of swimmers out and recycle the trunk for the next pair. Launching even the number of men required to handle the SB on deck could easily consume half an hour. In an attempt to find a faster way of getting swimmers in and out of a submarine, Fane and Kappeser made a daring and almost fatal attempt to test the feasibility of exiting and reentering through the submarine's forward torpedo tubes. As it turned out, the coarseness of the tubes' pressure controls caused sharp fluctuations of the

pressure inside the tube with the result that the swimmer's face masks were lifted off their faces. Fane did succeed in reentering the submarine through a torpedo tube but it was a close call. Johnson, who was filming this evolution, described it in detail. His description is quoted in Fane and Moore, *op.cit.* Fortunately, both Fane and Kappesser emerged from this experiment without serious damage, if somewhat shaken.

Other hazards were ever present during all of these operations. The swimmers always had to be alert for any signs of impending oxygen toxicity; the characteristically rapid onset of oxygen toxicity symptoms, already mentioned, made timely detection a tricky matter. Fane, Johnson, Kappesser and I all experienced possible oxygen toxicity, CO<sub>2</sub> intoxication or both at one time or another during operations with QUILLBACK. Ironically, Kappesser was involved in three of these incidents. When Johnson experienced symptoms, Kappesser who was swimming with Johnson as his "swim-buddy" saw him to the surface safely and without acute symptoms. Fane and Kappesser himself also experienced symptoms at one time or another. One day while we were operating in the open sea far from QUILLBACK with a borrowed U.S. Army J-Boat as a safety boat, Kappesser and I were swimming together at probably 40-50 feet depth.<sup>5</sup> Everything was going well when I suddenly felt a slight twitch in the muscles of my right calf. For reasons I have never understood, aside from the characteristic feeling of well-being, the first symptom I had experienced earlier when going into a full-scale, convulsive seizure, was that same twitching. As soon as I felt it that day, I immediately jerked on our "buddy line," pointed toward the surface, ripped off my face mask, inflated my breathing bag and shot toward the surface with Kappesser close alongside. Luckily -- really luckily -- the symptoms didn't progress but LCDR Johnson who was in the J-Boat told me later that I was very flushed and that I babbled unstoppably for the next fifteen or so minutes. Thanks to Kappesser and previous experience which allowed me to recognize the first symptoms, I avoided a dangerous oxygen toxicity incident.

Less serious if promptly treated but still capable of disabling a swimmer temporarily were easily infected coral cuts and very painful, multiple punctures by sea-urchin spines, sustained frequently during shallow water operations. (Some of us, while based at St. Thomas had learned from local fishermen that urine is the best treatment for sea urchin wounds.. With 21 spines in the instep of my foot one time, the pain was sufficient for me to test the treatment. It works.) Ear infections also were relatively common. When he was present, Dr. Lambertsen lined us up every morning and swabbed our ears out with preventive medication.

By the time these operations in the waters off the American Virgin Islands took place, the U.S. Army Chemical Warfare Service had taken over the abandoned U.S. Navy Base. Army/Navy relations probably have never been better than they were at St. Thomas. When we weren't working with a submarine and SUBOPS men were at St. Thomas, often for several months at a time, the Army post housed us, subsisted us and gave us material support as if we were part of the Army contingent. During one extended stay, annoyed by the prices of bar drinks in Charlotte Amalie, the SUBOPS men chipped in to buy a keg of rum. They kept the keg in the Military Police post at the entrance to the base and drew their nightly requirements on their way out of the base. The Army made the sturdy, wooden J-Boat (somewhat similar to an old-style,

---

<sup>5</sup> A maximum allowable depth of 35' was later established for closed-system oxygen breathing apparatuses.

Navy, 50-foot Liberty Boat) available whenever needed. The J-Boat did yeoman service plucking SUBOPS swimmers from the water when they needed assistance. Al Jones and I were at the St. Thomas Army base with a dozen or so men at the time USS MISSOURI went aground in Hampton Roads. One evening, Al and I received an order from the Post Commander to appear in uniform at the Army's morning parade. Puzzled, wondering if we were going to be drummed off the post, we duly appeared the next morning. Then with the Army personnel lined up in front of us at attention, the Post Commander announced that the two visiting Navy officers were present because the Post Chaplain would offer a prayer for the U.S.S. MISSOURI and the U.S. Navy. The Army people thought that an hilarious joke.

SUBOPS returned to Little Creek with a clear sense of accomplishment and E.R.F. Johnson's film to document what they had achieved. They were ready to do some showing off. It may have been during this time that Fane somehow arranged to get Commander, Amphibious Force, U.S. Atlantic Fleet to visit The Brig for an inspection of SUBOPS and a briefing on its operations and future plans. The SUBOPS men worked around the clock to prepare The Brig and themselves for COMPHIBLANT's visit. The Admiral arrived on the appointed day, inspected SUBOPS Platoon and The Brig, witnessed dry demonstrations of the Lambertsen Lung and Sleeping Beauties, then viewed films of the operations in Pillsbury Sound. The oral briefing on future plans emphasized submarine-delivered beach penetrations as well as ship-assault missions. The Admiral's response was noncommittal. He complimented the men on their appearance and bearing but said little else and made no comment on what UDT had in mind for the future. Still, we felt that the affair had gone off well and we anticipated increased support, both material and psychological, in the future. We were stunned when a letter was transmitted through the chain of command several weeks later directing COMUDTLANT to confine future operations to conventional reconnaissance and beach clearance missions.

Fane was, however, not to be deterred. Development of the underwater capability would continue by the best means available. The directive did mean that we would place greater reliance on activities at New London and cooperation with COMSUBLANT, while SUBOPS would have to retreat behind its locked fence to maintain a low profile while at Little Creek.

A clear opportunity to exploit SUBOPS capabilities in conjunction with SUBLANT soon came. In late 1948, Atlantic Fleet cold weather exercises were announced. The fleet-wide exercises in the North Atlantic would include an amphibious "invasion" of the U.S. Navy Base at Argentia, Newfoundland. COMSUBLANT, Vice Admiral Fife, was to command the defensive forces at Argentia and he wanted UDT participation in a defensive role. At the same time, COMPHIBLANT expected UDT to carry out offensive operations which were at least reasonably within the parameters of the conventional UDT mission. The result was that SUBOPS was thrown into a dual role, playing both sides of the coin. While most of UDTLANT, Teams 2 and 4 embarked in surface ships for normal UDT operations on D-Day, a detachment of SUBOPS under Fane's direct command went to New London to embark in USS GROUPER commanded, I believe, by CDR Miles Refo, for transit to and operations at Argentia. The detachment was small because of the limited space aboard the old diesel boat. The addition of a dozen or so men to the complement of an already crowded submarine didn't make for the most comfortable conditions. Sleeping on torpedo skids or "hot-sacking" with the always cooperative submariners was the rule. We passengers also had to qualify in the use of the submarine's

compressed air operated head (toilet.) Fane, unfortunately, failed on his first attempt to master this technique. In addition to Fane, Foster, Bailey, Piotrowski, Rollins, Hale, Phipps, Baker, myself and probably five others made up the UDT group in GROUPER.

Arriving at Argentia ahead of the attacking amphibious force on D-2 night, we operated first in an offensive role. Leaving the surfaced GROUPER under cover of darkness, we landed on a small pocket beach, camouflaged our rubber boats and fanned out to conduct hinterland reconnaissance and harass defending forces. At open point, Hale and I broke into the office of the U.S. Naval Air Station's Base Motor Pool and liberated some records, including a map of the U.S. Navy Base. Usable intelligence? Perhaps not but the defenders would at least know that UDT had been there. Others scouted defensive positions. We raiders had just reassembled at a rendezvous point when we heard a jeep approaching. We scrambled for cover and then, as the jeep with two Marines in it arrived, ambushed it. When the startled Marine in the passenger seat of the jeep fumbled for his .45 cal. pistol, I drew my combat knife.<sup>6</sup> I was 99 percent certain that the Marine's pistol was unloaded but wanted to discourage the fellow just in case. I had no intention of using my knife although it would have been relatively easy to get him before he could get his sidearm untangled. I figured that we were both play acting. LCDR Fane, however, apparently assumed that I had been overwhelmed by adrenaline. He hurled himself across the hood of the jeep, knocked me aside, shouting at me to drop the knife. The affair ended amicably, though, when we explained to the Marines that they had been captured by a UDT raiding party. The two Marines thought that was great fun and promptly defected to our side. The entire UDT crew piled aboard the jeep to ride half-a-mile or so to a small, isolated pier where we talked a Navy boat into taking us back to recover our rubber boats, then carry us and the boats back to GROUPER.

GROUPER and our embarked SUBOPS crew shifted allegiances to join Argentia's defenders the next night, D-1 night. We had been directed by Admiral Fife to interdict the amphibious force attacking Argentia by conducting swimmer assaults to disable ships essential to the amphibious landing. GROUPER had withdrawn from the bay at Argentia after the D-2 offensive raid. After standing out to sea for some distance, GROUPER reversed and headed back toward Argentia, submerged this time. Commander Refo performed an incredible feat by guiding GROUPER over the rocky bottom of Argentia Bay deep into the amphibious objective area, within striking distance of the amphibious ships at anchor there.

This time, we locked out of the bottomed submarine to make free ascents to the surface, releasing inflatable boats on the way. Two objectives had been selected for the ship assault mission. Fane would lead some of the men to assault USS FREMONT, flagship of the Amphibious Assault Group. I believe that Fane and his crew intended to test a lightweight inflatable boat but shifted to a standard 7-man rubber boat when the lightweight boat was accidentally punctured. I don't know all of the details of that part of the operation; the group I was with was going in a different direction and we had our own concerns to think about. In any event, after attacking FREMONT, Fane and his crew were to return to GROUPER, swimming down to lock in. The second objective was an AKA (possibly USS OKANOGAN) which carried the Navy Beachmaster unit and the Marine Shore Party and their heavy equipment. These units

---

<sup>6</sup>Present day SEALs will probably be amused to know that back then, UDT men were not issued firearms as a general rule. Our standard weapon was a Kabar combat knife.

were critical to the establishment of a beachhead. A 7-man rubber boat coxswained by BM2 R.O. Rollins was to carry Chief Foster and me to a point roughly a half-a-mile from the AKA from where we would swim to make our attack. After dropping us off, Rollins and his crew were under orders to proceed to the next ship in the anchorage, there to surrender on board for safety reasons. After completing our attack, Foster and I were to swim about a half-mile to shore.

All of the UDT men wore heavy diving underwear and bulky, rear-entry, dry-suits for protection against the cold. (The monocellular material of which modern wet-suits are made had not yet become available; the World War II relics worn at Argentario were the only thing that UDT had at the time.) The assault swimmers each carried "Day and Night" flares in lieu of limpet mines. Limpets, either real or simulated, were not available and we had not had time to improvise reasonable dummies. If we reached our objectives without detection, we were to pull the "Night" ends of our flares, igniting brilliant red pyrotechnics to simulate the explosions of limpet mines against the ships' sides.

The exit from the submarine was, except for the trouble with the inflatable boat, uneventful and both groups started paddling toward their targets in choppy, frigid water. Fane and his group reached FREMONT undetected, popped their flares and, according to the umpire rules, put FREMONT out of action along with the commanders and staffs of the Amphibious Attack Group and the Marine Landing Force. Rollins crew dropped Foster and me in the water as planned and we began what seemed a very long swim to our target. Both of us had to fight the chop which, although not severe, was a tiring annoyance. Both of us began to feel dampness from condensation or minor leakage creep up the legs of our underwear. Such dampness inside a dry-suit which offers little insulation against outside water temperature can quickly cause dangerous chilling. Nonetheless, we made it to our target and were surprised to find no sign of security on deck. From what we could see, bobbing in the water at the side of the ship's hull, the AKA might as well have been unmanned. As I recall, we worked our way along the hull until we thought we were adjacent to the ship's engineering spaces in the vicinity of the salt-water intakes. We each pulled a flare there, two or three yards apart. Foster then worked forward while I worked my way further aft and we each pulled a second flare. At that point, we should have withdrawn and headed for the beach. However, after talking it over briefly with Foster, I decided that it would be best for us to go aboard the ship. Both of us were tired, becoming chilled and our "dry" suits were definitely leaking slowly. It was several minutes before a couple of astonished faces peered over the ship's rail approximately amidships. I yelled up at the faces, "This ship has been hit by four limpet mines and is sinking. Tell your Captain." "WHAT?" "This AKA is out of action. Tell your Captain." After a moment of stunned silence, one face disappeared. More faces now appeared over the rail and we called for a ladder. It took several minutes for the men on deck to get organized but a ladder was eventually lowered and we clambered on board. I repeated to the Officer of the Deck that the ship had been attacked successfully by UDT assault swimmers and that, under the umpire rules, the ship was out of action for twenty-four hours and I advised the OOD to inform the Commanding Officer. Foster found a bunk in the Chief's Quarters and I stretched out in my diving underwear on a Wardroom transom. Finding two underwear-clad strangers in their midst caused some consternation and no little curiosity the next morning. I had the dubious honor of making a courtesy call on a disgruntled Captain while clad in still damp, baggy, long underwear. I have always regretted my decision to board the ship rather than swimming ashore. Under actual combat conditions, there would of course have been

no question of not getting away from the ship. Even though we were in a training situation in which safety was paramount. there is no doubt that boarding the “sunken” ship to spend the night robbed our exploit of some of its impact.. I have always thought and still think that we would have made it ashore. Still, there was a very real danger of exhaustion or cramping overtaking one or both of us. So, despite my regrets, I think my decision was a wise one.

As it turned out, the Argentia story didn’t end with the “disabling” of FREMONT and the AKA. Rollins and his crew proceeded to the next ship in the anchorage as instructed only to find no security on deck and a landing net hanging conveniently over the side. Rollins couldn’t let that opportunity pass and decided to take matters into his own hands. He and his crew climbed the landing net and searched the deck stealthily until they found a sleepy OOD and deck watch huddled over coffee cups. Rollins promptly informed the OOD that the ship had been captured. After placing one of his men as a guard on the deck watch, Rollins sent the rest of his men to secure anyone they encountered who might interfere. Rollins then ordered the OOD to take him to the Captain. A sleepy U.S. Navy captain was soon thereafter informed by a Boatswain’s Mate, Second Class that his ship had been captured and was held in enemy hands.

Unrealistic though some aspects of these events might have been, it was indisputable that a submarine had been able to penetrate an amphibious anchorage undetected and that assault swimmers from that submarine had been able to reach and attack ships which were unprepared and completely vulnerable. I have no doubt that had this been a real situation and had we been carrying real limpet mines, we could have placed them for delayed detonation causing severe damage to or the sinking of two ships essential to the amphibious assault while a third ship was captured or, at least, would have suffered the killing of its captain and some of its crew. As it was, umpire rules required that these ships be put out of action for 24 hours. That would have made continuation of the amphibious exercise impossible. The umpire rules were suspended.

I don’t know what official evaluation was placed on this exercise by higher levels of the Navy hierarchy. However, the unofficial feedback we got from several fleet officers was quite derisive: we would never have attempted such an operation under actual combat conditions and we had only been playing unrealistic games.. Still, perhaps the matter was taken seriously in some quarters because, some time after Argentia, “defense against swimmer assault” was added to the list of annual exercises which Amphibious Force, Atlantic ships were required to conduct. More directly pleasing to us was Admiral Fife’s expression of delight with the success of our operation.

The Admiral’s approval affected several of us in a very practical way shortly after the Argentia phase of the Fleet Exercise ended. The Club Officer of the Argentia Officers’ Club ordered several of us UDT officers out of the Club one night because we were out of uniform (wearing rumpled, stained greens and sand shoes.) Although he was a nondrinker himself, Admiral Fife was in another room of the Club. Hearing of the incident, he immediately sent a staff officer to inform the Club Officer that we were to be allowed to remain in the Club as his guests and were not to be harassed.

In the meantime, SUBLANT personnel and the shops at New London had been at work on their own to improve their capability to support SUBOPS. It had become clear to both SUBLANT and COMUDTLANT that any tactically useful transport of a Sleeping Beauty

would require some means of housing it on the parent submarine. Most critical was the fact that the SB's maximum test depth was only 50 feet. Limiting the parent submarine to 50 feet during any but experimental or elementary training operations would be out of the question. New London solved the problem by converting a salvaged boiler casing fitted with a hinged, water-tight door and appropriate flood and vent valves. The casing was then mounted on the after gun-ring (foundation) of a fleet boat (USS THREADFIN, I believe.). Thus equipped with a SB "hangar" on its afterdeck, the submarine could operate anywhere within its own depth limitations while transporting the SB.<sup>7</sup>

In early 1949, the SUBOPS men were again off to St. Thomas to conduct training swims and improve their skills with the SB until the arrival of USS THREADFIN at which time, the submarine would embark them and an SB for participation in the annual Spring amphibious exercises at Viecques Island, P.R. By this time, the SUBOPS men were accepted as old hands on the Army post located on the old Navy base just outside of Charlotte Amalie. Our work consisted mostly of swims near St. Thomas or off Caneel Bay at St. Johns to improve our endurance as well as to insure that all of our equipment was in shape for the coming fleet exercises. The latter effort was thrown in doubt one day when we had been working with the SB in Lindbergh Bay, a half-mile or so from the Army post. Finished with our work for the day, I instructed Rollins to pilot the SB on the surface back to our base. Rollins was off the point of land which separated Lindbergh Bay from the piers at our base, running on the surface, when he experienced a battery explosion which blew off the watertight cover of the battery compartment. The SB immediately flooded and began to sink. When the explosion occurred, Rollins had the canvas splash cover zipped up tightly around his neck. To his horror, he found the zipper jammed. Trapped in the now submerged SB, Rollins coolly cut his way out with his combat knife.

In the meantime, the rest of us had returned to the piers in the J-Boat. When Rollins failed to appear within the several minutes it should have taken him to round the point of land into our view, we immediately took the J-Boat out to find him. We found him standing on an almost exposed coral head, not in the best of moods, but unharmed-- physically. The men soon located the SB lying on the bottom with the battery compartment cover nearby. We spent the rest of the day raising the SB and hauling it back to the piers.

LCDR Fane arrived at St. Thomas the following day on a previously scheduled visit. Needless to say, I was again -- deservedly -- in deep trouble for allowing a man to pilot the SB unescorted, even in a fully-surfaced condition. Rollins was safe and unhurt but the long-planned use of the SB during the amphibious exercises was now in serious doubt. I received orders to have the SB ready for Viecques -- or else. The men went right to work on the boat, however, and once again demonstrated their skill and versatility. There was no structural damage to the boat except that the screws which held down the battery compartment cover had been ripped out of

---

<sup>7</sup> According to Frank Hale, the hangar continued in use during post-SB years for storage of deflated and rolled-up rubber boats during transit. Hale and Phipps were on the deck of a submerged submarine one night to take the inflatables out of the hangar. The boats were jammed inside because of the residual buoyancy of trapped air. After a struggle, they got the first boat free only to have it pop toward the surface to the limit of its tether. Phipps, who had been pulling at that first boat got a wild ride to the surface. He allowed that his wild ride had been fun and told Hale, "Let's do it again.."

their sockets, destroying the threads of both screws and screw-seats. The battery was, of course destroyed. The men redrilled and retapped the screw seats to a larger size, fabricated a new gasket and a new battery was obtained.

We didn't know what triggered the explosion but it was clear that a dangerous concentration of hydrogen had accumulated in the compartment; the pressure vent on the top of the compartment cover obviously had not been adequate to prevent the build-up of an explosive concentration of battery gas. Something had to be done to prevent a reoccurrence. Chief Foster devised a CO<sub>2</sub> purging system utilizing a small bottle of compressed CO<sub>2</sub> connected to the battery compartment by copper tubing, with a valve to allow the SB pilot to release a shot of CO<sub>2</sub> into the compartment periodically. By dint of long hours spent, the repairs were completed within a couple of days. But with all of their skill, dedication and hard work, the men could not have completed these repairs without the assistance of the Army personnel on the St. Thomas Army Post. Army men pitched in with materials, tools and advice as if the repair job was one of their own projects.

With fleet exercises underway and the amphibious phase approaching, THREADFIN got underway from St. Thomas, with the SUBOPS crew and SB embarked, to put out to sea from where it would make a submerged approach to the amphibious objective area off the Vieques beaches. LCDR Fane, E.R.F. Johnson, Al Dyer and an Army Reserve officer, a friend of Fane's, were also on board. Johnson suggested to Fane that he could attach an external flash gun to the previously described still camera, load the camera with infra-red film and provide an SB pilot with two or three infra-red flash bulbs to permit clandestine, night photography of the beach defenses. Such photography, provided to the approaching amphibious force in addition to the coded beach reconnaissance messages normally transmitted by radio would enhance SUBOPS's and UDT's reputations considerably. Fane decided to send me into RED Beach in the SB to obtain infra-red photography of the beach defenses. It was probably on D-2 night that the submarine made a long, submerged approach to the objective area, an approach made eerie in its final stages as the submarine scrapped over sandbars. About two miles off RED Beach, scraping bottom at periscope depth, the skipper bottomed the boat. Two pairs of swimmers locked out to unload the SB from its hangar. Then I locked out with a safety partner. and manned the SB.

After surfacing the Sleeping Beauty, I blew it dry and headed for RED Beach fully surfaced. Navigation wasn't difficult on the initial run in. The submarine's Navigator had given me a vector to RED Beach and I had my magnetic compass and the silhouette of Vieques Island stood out clearly so that I could pick out the approximate location of the beach. Only a slight swell was running and I didn't have to use my LARU on the initial part of the run in. About 400 yards seaward of the shallow bay on which RED Beach lay, I purged my LARU of air, put it on and went onto oxygen. Then, I trimmed down the SB to run with the deck awash; I was prepared to submerge quickly if I sighted any patrol craft but none were evident. There was a small islet in the middle of the RED Beach about 200 yards off the center of the beach. I decided to run in under the cover of that islet before submerging, skirt the island, then run fully submerged into the beach. Once submerged, running at a depth of about ten feet, I had to rely in my magnetic compass. I porpoised to the surface once for a quick look but saw no surface craft and I seemed to be on course for a point about half way between the center and right flank of the landing beach. With perhaps 50 yards to go, I cut my speed to SLOW and crept in until I bottomed the boat in about eight feet of water. I was then about ten yards from the waterline. I left the SB,

removed the camera from its well and screwed in one of my three infra-red bulbs. I began swimming, then crawling cautiously along the bottom toward the beach. I knew that I was well covered with water but was concerned about causing some surface disturbance or stirring up enough sand to be detected from the beach. Finally, in less than two feet of water, I slowly raised my head until my eyes were just clear of the surface -- and found myself staring at a Marine sentry leaning against a concrete tetrahedron about five yards away. I pulled back under and backed off a yard or two to get a little more water over myself, then put my head out again. The sentry was still there, maybe asleep, maybe dreaming about his girl friend, but apparently unaware of my presence.

The situation seemed perfect to me. I pulled the camera just above the surface of the water and fired one shot of barbed wire and jetted steel rails near the center of the beach, wound the film, replaced the infra-red bulb and took another shot, angled along the length of the beach. Then, unable to resist any longer, I went under again to creep directly toward the sentry until I was in water shallow enough that my head and butt were exposed. There, I fired the last of my infra-red bulbs, taking a picture of the sentry from no more than four yards away. It was hard for me to imagine that the sentry couldn't see me or something of the infra-red flash but the sentry didn't react and, as I backed into deeper water, I figured I had got away with it. However, by the time I relocated the SB, restowed the camera and got into the cockpit, I knew that my efforts had taken a toll. Whether from chill, although the water was fairly warm, excess adrenaline, or something worse, I was shivering vigorously. Still, I didn't believe that I was encountering any serious physical problem. Clearly, though, it was time to withdraw. I told myself to calm down and reached down to crack the air valves to bleed a little water out of the ballast tanks to lift the SB just clear of the bottom before getting underway.

Suddenly, something clapped me on the shoulder; then something else covered the glass of my face mask. It scared the hell out of me and I instinctively went for my combat knife. Fortunately I couldn't get the knife out easily in the cramped cockpit and before I could, a swimmer appeared in front of me and reached over to push the "assailant" away from me. The swimmer pulled off his face mask and stuck his face in mine but I had already recognized the friendly face of Al Foster. In the meantime, Foster pulled the Army Reserve major none too gently away from the area. I gave Foster a thumb up as the pair disappeared in the cloudy water. As it turned out, after I left the submarine, Fane had directed a rubber-boat crew under Chief Foster to conduct a surface reconnaissance of RED beach. He authorized the major to accompany the UDT crew as an observer. The good major not only risked blowing the operation but, in the instant before an alert Foster calmed the situation, risked getting himself knifed.

Somewhat calmed down, I ran out from RED Beach at a depth of about ten feet until I thought I was clear and then blew the ballast tanks until I was running awash. With no beach silhouette to rely on and nothing but the tip of a submarine periscope as a target, I had to rely entirely on the magnetic compass and clock for navigation. It had taken me about an hour to run into the beach so I figured that I would run to seaward for an hour, keeping the best magnetic course I could, then run parallel to the beach searching for the submarine.

Once well clear of the approach to the bay on which RED Beach was located, I blew the tanks and surfaced fully. But the seas were beginning to develop a noticeable chop which was

creating quite a bit of spray so I stayed on oxygen for a while. It wasn't long, though, before I started to get a headache and realized that I was no longer thinking very clearly. I thought that the Baralyme canister of my LARU must be leaking and that I was experiencing the first stages of CO2 intoxication. At that point, running fully surfaced, I closed my oxygen supply valve and removed my face mask. I wanted to save what was left of the capability of the LARU to get me back into the submarine. I was taking a lot of spray in the face by this time, it was very dark, I wasn't keeping a very steady course in the chop and I wasn't at all sure of where I was or where the submarine was. Once, I considered turning around and running back in on the surface to beach the boat. There was no way I could miss Viecques Island. But that would have negated everything so I kept going. By the time an hour and a half had elapsed, I was getting very worried.

Then, out of the darkness, I heard, very faintly, a long, drawn-out "Brigadoon"<sup>8</sup> At first, I thought I was hallucinating, done for. But I turned toward the sound and, a minute or so later, heard it again a bit louder. I steered directly for the sound then and, a couple of minutes later, saw a dark, bulky silhouette. Suddenly, there was Chief "Andy" Devine hanging to the submarine's extended periscope calling out at the top of his voice. I think it was luck more than anything else but I had missed the submarine by only a hundred yards or so. There was no question though, that had Andy Devine not made himself into a human homing beacon, I would have gone right on past, out to sea -- or would have exhausted myself searching fruitlessly for a slender periscope in a very large Caribbean Sea. A recovery crew soon popped to the surface and, too far gone to trust myself to take the SB down, I asked Kappesser to take the boat down on deck. I immediately put my face piece on, went back on oxygen and went on down to be locked in.

Back in the submarine, I sat in the wardroom babbling excitedly, or so they told me later. I felt exhausted but, at the same time, exhilarated. I guess I knew that I was rattling on like an idiot but I simply couldn't shut up. For one thing, I was waiting anxiously for Al Dyer to develop the film. There was nothing I wanted more than to see the picture I had taken of the Marine sentry in the middle of a dark night from a distance of a few yards without being detected. Finally, Johnson appeared in the hatch of the tiny wardroom with a glum expression on his face; Dyer was standing behind him. As gently as possible, Johnson told me that the film had come up blank. "My God," I thought, "what did I do wrong?" "In that first moment, I felt that I had blown the whole operation. Johnson, though, quickly told me that it wasn't my fault, that there was no way I could have known and nothing I could have done. When the developed film came up blank, they checked the camera and found that the flash was a fraction of a second out of synch with the camera's shutter. It wasn't anyone's fault, just Murphy's Law at work. Despite later reports to higher authorities that night photography of the beach had been obtained, there weren't any pictures. For me, it was a bitter disappointment and I know that Johnson and Dyer felt just as bad. Still, we had added another notch to justification for submersible operations. We had pulled off the operation, the men on the launch and recovery crews, the THREADFIN's skipper and his crew and, of course, Andy Devine. We had proved that we could do what we set

---

<sup>8</sup>One morning in The Brig when I was mouthing off with some specious profundities, QM3 Barney Weathers announced, "Thank you Finian J. Brigadoon." referring, of course, to "The World's Smartest Man" character in the "L'il Abner" comic strip. Weathers put neatly in my place and tagged me with a nickname which still persists in certain quarters.

out to do and, in the end, were stymied only by a technological glitch. Murphy's Law.

There were a good many new faces back at Little Creek by this time. Except for LCDR Fane, the wartime officers had all left. LTJGs Bill Huckenpoehler and Jim Paulick, Naval Academy alumni, had graduated with Replacement Training Class 3. LTJGs Arsenault and Howard had arrived from the Explosive Ordnance Disposal Unit at Indian Head, Maryland.. They were the only nonvolunteer officers to enter UDT at that time but the addition of explosive ordnance disposal skills was clearly to UDT's advantage. LTJGs Boule, Moore, Clark, Smith and Huddleston qualified during 1949 or 1950. LTJG "Mac" McStay completed training despite a good ten years in age on most trainees. He was a former Chief Warrant Gunner and an acknowledged expert on explosives. Mac taught us such niceties as using explosives of different firing rates in the same array of charges to achieve maximum effectiveness in such tasks as ramping sand scarps, foreshadowing the sophisticated techniques now used to demolish large buildings.

One of the training classes had enough officers to constitute an all-officer rubber boat crew for the "Around the World" course during Hell Week.<sup>9</sup> Clark, Smith and Boule were part of that officer crew. Al Jones and I, as Training Officers for that class, rode the trainees unmercifully during that night exercise, tracking them all the way, jumping them from ambush whenever someone cursed an obstacle or tried to light a cigarette. The officer crew almost had it made that night when I caught them portaging their boat along a paved stretch of road on a shortcut back to Beach 7. I ordered them to go to Beach 7 and start over. They finished their second time over the course sometime the next afternoon. I don't think those guys have ever forgiven me but I must say that they really earned their subsequent qualification.

SUBOPS itself remained fairly stable. All selected volunteers, most of the men stayed with UDT and SUBOPS although, as previously noted, some were absent for periods of special training and, as some men left for other duties or to leave the Navy, selected replacements from later training classes joined SUBOPS. New faces from outside UDT also "joined" SUBOPS from time to time. Army Warrant Officer Williams, a reconnaissance expert and skilled photographer was detailed to six months' temporary duty with UDT and was assigned to SUBOPS during that period as Assistant Platoon Officer. Fane was able to bring in Count Roberto Frassetto, a former Italian Navy officer who had participated in swimmer and small submersible assaults on British warships in the Mediterranean Sea during World War II, to Little Creek. He spent several weeks with SUBOPS, giving us the benefit of his experience. Frassetto returned to Little Creek several times during the next few years.

Another visit to UDT and SUBOPS at Little Creek was to have a profound effect, not only on UDT, but on American society and its recreational customs. While SUBOPS was doing its work at Little Creek, New London and in the Caribbean, a French Navy officer, Commandant Jacques Yves Cousteau (not as famous then as he came to be in later years,) had been pursuing vigorously the development of underwater swimmer capabilities for the French Navy. Cousteau

---

<sup>9</sup>The Amphibious Base at Little Creek had not yet been paved over. The all-night rubber boat exercise called "Around the World" took the trainees over rock jetties, through marshy areas where the trainees had to find there way through a tangle of open channels, most of which led nowhere, through the swamp into which the bases's waste disposal plant discharged, along narrow drainage ditches clogged with rocks and stumps. It was a tough exercise.

was concentrating his effort on use of an open-system, non-recirculating breathing apparatus in which compressed air is fed to the diver through a three stage pressure valve, then exhausted to the sea as the diver exhales. Such an apparatus had the advantage of virtually eliminating the danger of oxygen toxicity although the diver did remain vulnerable to other common diving hazards. Fane had heard about Cousteau's work. He made contact with Cousteau, then met with him when Cousteau visited New York. As a result, in the Spring of 1949, Emile Gagnon arrived at Little Creek with a one-bottle Cousteau unit. Gagnon was an engineer employed by Cousteau and the key designer of the air pressure regulator which was the heart of the Cousteau lung. Gagnon spent several days with the SUBOPS men, teaching them how to use and maintain the Cousteau equipment.

Shortly after Gagnon's visit, SUBOPS again deployed to New London. There, Fane made the first dive ever in the United States with the Cousteau-designed breathing apparatus. SUBOPS men followed Fane in diving the gear in the 100' tower. Not long after that, Cousteau licensed the manufacture of his equipment in the United States where it was first put on the open market under the trade name, Aqua-Lung . SUBOPS quickly acquired a number of two-bottle Aqua-Lungs .

Although the Cousteau system open system offered obvious advantages for SUBOPS work, particularly the ability to dive deeper without worrying about oxygen toxicity, we weren't ready to give up on closed, recirculating oxygen systems. I, for one, was concerned with the loss of concealment caused by the stream of bubbles emitted by an open-system apparatus. Others objected to the mouthpiece which replaced the face-covering mask of the LARU and the loss of voice communication between swimmers. Hale and Rollins, who often swam together, learned Basic Sign Language so that they could communicate by hand while using Aqua-Lungs. Although the two bottle Aqua-Lungs obtained by UDT provided ample dive time, they were much bulkier than the LARU, making exits from submarine escape trunks even more problematical. The Aqua-Lungs also created a pesky logistics problem for SUBOPS. Pure oxygen of breathing quality for the LARUs had been readily available from the Navy supply system, the same oxygen used by aviators. We needed much larger volumes of compressed air for the Aqua-Lungs . Ironically, compressed air which one would think more easily available than pure oxygen wasn't available, not in breathing quality. When it was available in large tanks, it was often contaminated with oil and other impurities. We got a commercial compressor but, like most commercial compressors, it didn't provide oil-free air. As they did so many times in those years, the SUBOPS crew went work to jury rig a filter system using old oxygen bottles filled with diatomaceous earth. However, the home-made filter system never worked very well. Finally a very expensive commercial compressor designed to provide breathable compressed air was obtained.<sup>10</sup>

---

<sup>10</sup>In those days, the quarterly operating allotment of each Underwater Demolition Team was \$400. That was intended to cover all of the ordinary material and supply expenses of the team. Overexpenditure could result in severe sanctions against the commanding officer. UDT men, in these circumstances became adept at begging, stealing, borrowing and improvising. For something like Aqua-Lungs an expensive compressor, funds had to be obtained from higher commands: from COMPHIBLANT or BuSHIPS, for example. Higher commands weren't always enthusiastic about funding the wish lists of unorthodox units such as SUBOPS. It fell to LCDR Fane to find and justify funding sources for special items. At our level in SUBOPS, we didn't always know how he did it, but he was very successful. .

Despite the advent of Aqua-Lungs, research into the physiology of oxygen toxicity was continuing at New London so the visits to the Submarine Base continued. On one of these visits, Fane and several of the most experienced SUBOPS men undertook a grueling series of experiments in the large compression chamber at the foot of the 100' tower. The purpose of these experiments was twofold: first, to test the swimmer's endurance on pure oxygen at increasing increments of pressure; second, to try to get blood samples from swimmers who were just at the threshold of acute oxygen toxicity so that the German physiologist, Dr. Schaefer, could conduct blood analyses. The pressure chamber was filled with about three feet of water. Air pressure in the chamber was then increased until it equaled the hydrostatic pressure of sea water at the desired depth. With appropriate air pressure in the chamber, swimming in three feet of water was physiologically the same as swimming at 10 feet, 20 feet, whatever the selected test depth. The swimmers, wearing LARUs and breathing pure oxygen, were to swim laps around the tank continuously until they began to experience adverse symptoms or until the test at that depth was halted. This became a very boring and, as the air and water in the tank warmed under increased pressure, tiring procedure. There is nothing like swimming around in tight, little ovals (the chamber was probably about 10' x20') for several hours on end. The test started at a simulated depth of ten feet and increased in ten foot increments. In addition to the chamber operators from the tower staff, UDT's medic, HMC Drane, was at one corner of the tank observing each swimmer as he passed, trying to detect any sign of a possible problem. Nothing happened until we had been working for some time at, I believe, the 40' level. Once again, I was the first to go.

My experience provided an excellent example of the insidiousness of oxygen toxicity. Dr. Schaefer had talked to the swimmers time and again about euphoria being one of the very first symptoms of oxygen toxicity.<sup>11</sup>

I was rounding the corner at Chief Drane's end of the tank, feeling very strong. I saw Drane stick his head under water to check me out and I gave Drane a thumb up. Then, I realized that I had been laughing as I signalled Drane and, an instant later, I felt the characteristic twitching of a muscle in the calf of my right leg. I knew instantly that I was just at the threshold of acute toxicity. I can still remember that I felt very good, even sort of proud, because I was certain that I was right on the threshold but wasn't going out. Doc Schaeffer was going to love my blood. I immediately stood up, closed my supply valve, ripped off my face mask and took a deep breath of ambient air, still thinking that I was fine. Then I felt myself tipping over backwards and starting to floating up into the air.

My experience might have demonstrated another aspect of oxygen toxicity. Oxygen toxicity was thought to be intimately related to CO<sub>2</sub> levels; it was thought that increased levels of CO<sub>2</sub> lowered the threshold of oxygen toxicity. Although I probably would have convulsed anyway -- once you detect symptoms, you are usually gone -- I didn't go fully out until I removed my face mask and took that first full breath of ambient air. It turned out that the air in the chamber hadn't been recirculated for some minutes and there very likely was a relatively high concentration of CO<sub>2</sub> in the chamber. It is possible that I might have been a good subject for Dr. Schaefer until that first breath of CO<sub>2</sub> laced air kicked me over into a full-scale epileptiform convulsion.

---

<sup>11</sup> We were always amused by the Herr Doktor's rich, rolling, Germanic pronunciation of what we called "youFORia" -- he pronounced it, "oyphorEEa."

I knew nothing else until I woke up momentarily in the lobby of the Base Dispensary where some idiot was tickling the sole of my foot and asking me stupid questions: what was my name, where was I, what month and day of the week was it? I apparently answered all of his questions correctly until he asked me what year it was. I told him, "1789" and the next things I knew was when I woke up in a Dispensary bed several hours later feeling as if I had just finished 60 minutes of football with the Chicago Bears. I also began to feel quite depressed because I figured that my days in UDT were over. Fane would never put up with an officer so weak as to have suffered epileptiform seizures on two occasions. About then, I heard incoherent noises from the bed next to mine. My sense of depression passed when I rolled over to look and saw Fane lying there, muttering, "Where am I?" I was released from the Dispensary the next morning, with a permanent entry in my Medical Record that read, "LTJG Bruce Dunning was released from the Dispensary, U.S. Navy Submarine Base, New London this date with a minimum of mental confusion."

Following these deep tests, it was decided that we should run some simple endurance tests in shallow water. This time, the swimmers were to swim laps in the Base Swimming Pool, wearing LARUs, of course. This was simply a control test to determine if oxygen toxicity could be induced at shallow depths by fatigue alone, or if depth and its accompanying pressure was the crucial factor. With the convulsive experience in mind, Fane made sure that each swimmer was willing to participate. Although I doubt that any of us were excited by the prospect of swimming endless laps in a swimming pool all of the SUBOPS men agreed. One officer and two or three enlisted men who were not regularly assigned to SUBOPS opted out. In any event, we swam for probably a couple of hours with no one experiencing any symptoms. The only results were a bunch of tired swimmers. While this exercise didn't prove anything, it supported the hypothesis that pressure was the villain in oxygen toxicity.

I think that both the work on oxygen with the old LARUs and the advent of Aqua-Lungs have had curiously intertwined effects which we didn't recognize in those days. Much of the equipment that present-day SEALs, for example, have available simply hadn't been developed. Except for UDT and a few pioneers such as E.R.F. Johnson and Dr. Lambertsen, skin diving in those days consisted mostly of a few people equipped with swim fins, face masks and "schnorkels" which had been brought to the public's attention when UDT's wartime exploits began to be publicized. Cousteau's development and the Aqua-Lung changed all that, starting the skin-diving rage and a subsequent increase in research and development of underwater equipment. I suspect that the rapid increase in the public's interest in the underwater environment also stimulated the Navy's growing interest in exploiting that environment with combat swimmers. In any event, new equipment which combined the relative safety advantages of the Aqua-Lungs with the concealment advantages of closed systems were soon to appear. However, I may be speaking out of turn: the mixed-gas systems now available to SEALs appeared after my time in UDT and I have only the vaguest knowledge of them. But I would like to think that the work that we did back in the late 40's, with both types of breathing apparatuses, contributed not only to the development of modern equipment for combat swimmers but also to the recreational revolution which made "SCUBA-diving" available to almost anyone.

UDT at Little Creek was in almost constant demand for demonstrations, sometimes carrying out their usual reconnaissance and demolition missions during amphibious landings

conducted for the public, sometimes providing both static displays and dynamic demonstrations at special events. These demonstrations were so popular that, at one point, the Secretary of the Navy personally “requested” that UDT provide both a static display and a dynamic demonstration during all-Service demonstrations at the Ordnance Manufacturers’ Association Convention at Selfridge Air Force Base near Detroit. The Secretary’s request specified that we should include the use of explosives. Needless to say, UDT complied. But with only three days warning, the UDT detachment had to hustle to get to Detroit with both a static display and explosives for a dynamic , beach-clearance demonstration. The request from SECNAV came on a Sunday by a telephone call from the Secretary’s Military Assistant. I happened to be the UDT Duty Officer that morning and had to get things rolling so that a good part of the detachment lined up for the show came from SUBOPS. Sam Bailey and George Kudravitz took off early on Monday with explosives loaded in a truck pried out of Little Creek’s Base Motor Pool. We tapped “Dusty” Rhodes to go along as coxswain of whatever kind of boat we could borrow from the Air Force at Selfridge. Sam Bailey, Foster and Devine got the rest of the crew moving putting together whatever material they thought might be useful in a static display as well as fabricating dummy obstacles out of Celotex. The rest of us flew to Detroit just in time to get set up for the show. The static display in an Air Force hangar attracted considerable interest but the payoff came with a dynamic demonstration of a beach clearance mission on Lake St. Clair before a crowd of several thousand people. Actually, our show was pretty routine: cast of swimmers from an Air Force rescue skimmer, placement of charges on dummy obstacles, recovery of swimmers, then a second boat run to snatch the fuse puller from the water seconds before the scheduled detonation. (The charges actually were fired electrically by Foster and Devine, hidden under the grandstand..) But the “fuse puller” that day was GM2 Hugh Peddy who, I emphasized in my commentary, was born and raised in Hamtramck. The crowd loved it. Because of Peddy, the next day’s press coverage of the day’s demonstration was dominated by UDT’s part, much to the chagrin of the Air Force.

There was a continuing effort to think up new and more dramatic ways to demonstrate UDT capabilities. Desire to spice up static displays and SUBOPS’ search for a way to display their capabilities led to a new SUBOPS project. Some of the SUBOPS men had served as underwater observers while landing craft were run at full speed into beach obstacles as part of joint Army-Navy tests of beach obstacle designs. Commanding Officer, Construction Battalion 2, based at Little Creek was the Navy coordinator of these tests. The CB commander had taken advantage of SUBOPS’ performance during these tests to stress on his Army and Marine Corps counterparts the versatility of the Navy. He owed SUBOPS one. So, the CBs delivered one of their modular pontoon sections to The Brig. This was a heavy-steel cube, approximately 7’x7’x7’. SUBOPS men , with John Dolan as lead welder, first cut out the top of the cube, then cut a large window, about 6’x6’ in one side. Using materials begged from various sources, they devised a frame and gasket system to hold a 1/2” tempered glass window over the opening so that the assembly was watertight. Unfortunately, the glass had to be purchased with team funds and it didn’t come cheap. Even more unfortunately, the glass window cracked the first time we tried to tighten down the frame. The project almost came a cropper at that point. But someone got the idea of using Plexiglass. A sheet of very heavy Plexiglass was obtained by some unreported means. With the Plexiglass in place, the men started to fill the tank with water. It was a dicey half-hour or so while the tank filled because, if the Plexiglass were to break, that much water would come out with explosive force. The Plexiglass held. From then on the tank was used

in displays for a good many years. Swimmers wearing lungs cavorted in the tank, waved to spectators, showed off in all sorts of ways. A bunch of hams. One of the favorite ploys was to put two men into the tank for a game of checkers using a checkerboard of steel plate, with painted washers as checkers.

But the demand for UDT participation in demonstrations was to lead to a major tragedy. During a good many demonstration amphibious landings, UDT was required to simulate the explosions on the beach of gunfire from Navy ships offshore as well as bombs and machine-gun fire from supporting aircraft. UDT men became quite proficient at using controlled explosives Hollywood-style to simulate naval gunfire and air bombardment preparation of landing beaches. But higher authorities always wanted more realistic simulations. One of the demands was for simulated anti-aircraft fire, supposedly from defending forces on the beach. The 4th-of-July type Roman candles the UDT men usually used weren't very convincing. Mac McStay came up with the idea of using a Ship's Emergency Identification Signal (SEIS) and modified SEIS projectiles to simulate the airbursts of anti-aircraft fire.

SEIS projectiles were aluminum canisters containing a small propelling charge, a bursting charge and a pyrotechnic element attached to a parachute. On being dropped into the mortar-like SEIS tube, the projectile was propelled about 150 feet into the air at which point the canister was burst, the parachute deployed and the brightly-burning pyrotechnic element floated down. McStay taped a M3A3 hand-grenade detonator into the detonator well of a 1/2 pound block of TNT, replaced the pyrotechnic element of the SEIS projectile with the primed TNT block and attached the parachute to the TNT block. To fire a charge, the pin was first pulled from the hand-grenade detonator. But with the actuating lever of the grenade detonator held tightly within the SEIS canister, the TNT theoretically could not detonate until the projectile was dropped into the mortar tube and propelled into the air, at which point the bursting charge would fire. Bursting of the canister released the actuating handle of the grenade, initiating the three-second delay of the M3A3 detonator. The TNT block would then float down on the parachute until it detonated at an altitude of about 90 feet. Test shots at Little Creek apparently worked perfectly.

In late August of 1949, UDT 2 deployed on an LST to participate in a demonstration landing at Atlantic City, New Jersey while the Miss America contest was being held there. UDT's part in the Atlantic City demonstration was fairly routine: cast and recovery of reconnaissance swimmers, destruction of dummy obstacles and use of controlled explosives on the beach to simulate both friendly naval gunfire and enemy fire. SUBOPS was ashore throughout D-1 afternoon and night, setting up the beach. It would have been a boring operation were it not for Miss America activities and the presence of numerous sightseers on the Boardwalk. Frank Hale recalled standing on the Boardwalk watching a Miss America photo-op session when a little old lady walked up to him and said, "If someone hit you on the head with an ax, little, hairy things would come flying out." Then she walked off. It takes all kinds. Bored, cold and hungry after a night spent on the beach with only a catnap under the Boardwalk and a little resentful of all those people sleeping comfortably in luxury hotels, I held 6:00 a.m. reveille by firing a two-pound block of tetrytol. It got the public's attention.

After the Atlantic City demonstration, the amphibious task group proceeded on to Boston

where a battalion-sized amphibious landing was scheduled to be held on Carson's Beach, a large public beach and park in South Boston. The landing was to be a feature of a convention of the Marine Corps League and interest from the highest levels of the Marine Corps and Navy was strong. McStay decided to use his "anti-aircraft" mortar there. Additionally, a large and complex field of controlled explosives was planned. The day before landing was devoted to laying in the controlled-explosive fields. Several SUBOPS men were working with McStay on the beach. Most of the rest of us from SUBOPS were responsible for about half of the park inland from Carson's Beach itself while other men from UDT 2 were working the other half of the hinterland. The whole operation got off to a bad start on D-1 Day when the Boston Police suddenly and without warning withdrew their security perimeter around the park at midafternoon and the area was immediately overrun with homebound school children. Before we could get the situation in hand, a dozen or so 1/2 pound blocks of TNT were stolen. The blocks were unprimed and, by themselves relatively harmless. Nonetheless, the possession of explosives by any number of unidentified persons caused Navy and Boston authorities grave concern. The public was not yet aware of this development. Then, shortly after the demonstration landing started on the following day, one of McStay's anti-aircraft charges exploded in the mortar tube. Exactly what went wrong in the tube of the mortar has never been fully explained, but the shattered mortar threw shrapnel directly into a crowd of Navy personnel and press representatives at the center of the beach. McStay had apparently spotted something wrong and tried to throw himself across the mortar but a piece of shrapnel struck Morris Fineberg, a highly-respected Boston news photographer, in the head killing him instantly. One other bystander, a Navy officer, received a non-life-threatening flesh wound. Mac McStay himself received severe shrapnel wounds in the abdominal area. UDT's HMC Drane was at Mc Stay's side immediately but despite all of his efforts, McStay's condition was grave when he reached a hospital a few minutes later. LTJG McStay died of his wounds a few days later. It is likely that McStay's effort to cover the mortar prevented many more casualties.

Those of us on controlled-explosives detail inland from the beach got a clue that something had happened when we heard Fane's voice come over the public address system. Fane prevented possible public panic when he grabbed the microphone away from the hysterical assigned narrator and, ad-libbing, continued the narration of the show's events. That something serious had happened was confirmed to us in our fire-control point when a UDT man from the beach passed at a dead run on his way to summon an ambulance parked at the perimeter of the park and shouted to us that the mortar had exploded.

The tragedy inflamed public opinion, made worse when news of the missing explosives became known. Then, the affair became embroiled in Boston politics at a time when Mayor Curley was fighting to retain office in what was to mark the end of his political career. The affair received front-page coverage in the news media, of course, and the media were assiduous in covering related developments for some time. However, I was impressed by the fairness of reporters when, on several occasions, they asked me for explanations of apparently contradictory statements before they rushed stories into print.

A deeply saddened UDT2 returned to Little Creek from Boston, less several officers and a number of men who remained in Boston during a long and ultimately inconclusive Court of Inquiry convened by Commander, First Naval District. After the inquiry, a detail from SUBOPS

remained in Boston for several more weeks searching Carson's Beach and the park, even covering the bottom of Boston Harbor with a Naval Shipyard designed "plow" towed by a yard tug. All that plow achieved was to stop the tug dead in its tracks as the plow buried itself in the bottom muck. The men patrolling the beach did recover one water shot, a 2 lb. block of tetrytol which floated ashore. That was the only primed charge missing during the operation. It was in the hands of a SUBOPS man within a minute of being found by a boy. As I recall, few if any of the unprimed TNT blocks missing from the Park on D-1 afternoon were ever recovered.

Back in Little Creek, UDT and its SUBOPS element tried to put Boston behind them and get on with their work. The first opportunity to give Aqua-Lungs a rigorous, operational test came in December, 1949 when CINCLANTFLT asked UDT to attempt to clear a wreck lying in 60 feet of water in Chesapeake Bay. Conventional divers had been unable to make much progress in removing the menace to navigation because of swift tidal currents which limited their dives to short periods of slack tide. Fane led a detail of SUBOPS men on Aqua-Lung dives to the wreck to place explosive charges while the ubiquitous Fen Johnson photographed the proceedings. Working under extremely severe conditions for a number of days, Fane and his crew were able to demolish the wreck. Fane, Johnson, Devine, Foster, Bailey, Piotrowski, Petway and Kappesser received Letters of Commendation from CINCLANTFLT for their work. The knowledge of the men who had gone to deep-sea diving school was especially valuable during this operation since they were well-trained in the limits of diving stay-time as well as in the use of decompression tables, absolute necessities in sustained air dives with the Aqua-Lung

I played no part in this operation.

In early 1950, it was off to St. Thomas again for SUBOPS. The deployment was marked at the outset by a typical hassle with "conventional forces." The SUBOPS detachment, along with a large amount of equipment and half-a-ton of explosives was transported from Norfolk to Roosevelt Roads, P.R. in an AKA which also carried a large contingent of Marine service troops. From there, a LCU was to take SUBOPS and the gear to St. Thomas. On arrival at Rosie Roads, I found the LCU beached on a ramp several hundred yards from the AKA's berth. That night, I contacted the Marine captain who was CO of a transportation company and got his promise to provide a 6x6 truck to transfer the explosives and gear from shipside to the LCU on the following morning. As soon as the explosives and gear were offloaded from the AKA, the UDT men started loading the truck provided by the Marine captain. The truck was about half loaded when an irate Marine colonel appeared on the scene screaming that we had no authority to "commandeer" a Marine vehicle. I tried to explain that I had requested and received permission to use the truck for one trip and turned to the CO of the Transportation Company for confirmation. That sterling officer promptly denied that he had ever given such permission and denied ever talking to me. Threatened with court-martial and ordered by the still raging colonel to unload the truck, the men started doing so, piling it on the pier and covering it with a tarpaulin. More for appearance's sake than urgent need, the men started wetting down the tarp with buckets of water. Hauling all that material to the LCU on foot would have taken days. So I went aboard the AKA, found the Executive Officer, told him there was half-a-ton of explosives sitting on the pier next to the ship's side in imminent danger of "cooking off" (a gross exaggeration) and that transportation was urgently needed. The Exec found his Captain who immediately rushed to the pier to find the Marine colonel. After lengthy negotiations, the still incensed colonel relented, but

only after making it clear to me that any recurrence of the affair would mark the end of my career and extracting a promise that the truck would be returned in 15 minutes. Of course, it took over an hour to load the truck, move it to the LCU and unload it. Either the colonel forgot about the time or couldn't find us and we were soon off on a slow, pleasant cruise to St. Thomas. I must add that the case of the purloined truck was an aberration: UDT and Marines, especially Marine reconnaissance units, often worked together and enjoyed considerable mutual respect.

It was probably during this deployment that Al Jones and I were ordered to use explosives to turn a rocky shoreline into a sandy beach. A former Navy hospital at the edge of a small bay near Charlotte Amalie had been turned into a hotel. The hotel owner didn't have a nice sand beach for his guests and he wanted one. Fane negotiated a deal to exchange our transformation of the beach for a steak dinner for the UDT men. We worked for a couple of days but succeeded only in making slightly smaller chunks of coral out of very large reefs -- no sand. (I learned there that "mud-capping" doesn't work with sand.) Fane came by to inspect our progress and, seeing none, directed us to use larger charges. The operation ended when, under the influence of increasingly large charges, a crack appeared in the concrete-block front of the hotel from eave to foundation. Fane must have been persuasive, though, because we got our steak dinner anyway.

With fleet exercises commencing, the SUBOPS crew again embarked in a submarine at the St. Thomas pier and headed for Viecques to conduct reconnaissance on Red Beach. I believe that it was during this operation that a 7-man rubber boat lashed on the afterdeck of the submarine broke loose as the submarine approached the objective area at periscope depth. The skipper, using his periscope, suddenly saw a rubber boat flapping around in the current. Both Fane and the submarine's skipper were understandably incensed at this example of sloppy seamanship. The submarine surfaced so that a crew could go on deck to secure the boat. Moderately rough seas were running and fairly large waves smashed over the deck of the nearly awash submarine. The crew trying to corral the boat took quite a beating. Hale was battered when he got caught between the lurching boat and the after part of the conning tower. I had gone forward of the conning tower to retrieve something and was slammed into an ammunition locker, jamming my leg between the handle on the hatch and the hatch itself. When the boat was secured and we returned below, I found a 3/4", bone deep split in the flesh of my shin. Joe DiMartino and I had been scheduled to make a two-mile swim later that night to the small islet off the center of Red Beach, there to remain throughout the next day, observing and photographing the beach. On the next night, we were to swim back out to sea to be picked up by the submarine. I wasn't wildly enthusiastic about the prospect of two long night-swims and even less enthusiastic about spending a full day sitting under a hot sun on top of a treeless, guano-caked rock. Besides, we had no good way of waterproofing the 35 mm. camera we were to use; we didn't have one of Johnson's waterproofed cameras. I don't really know but I think Di Martino was just about as unenthusiastic as I was. In any event, I chickened out and used my "wound" to get Fane to cancel our mission.

Not long after SUBOPS returned to Little Creek, LCDR F.D. Fane was transferred to the West Coast teams where he continued his pioneering work in underwater operations. Most of the SUBOPS men were busy training yet another Replacement Training Class when CDR Raymond A. Hundevadt, USN (now deceased) arrived to take over as COMUDTLANT and CO, UDT 4.

At about the same time, LCDR L.L. Hoyt, USN, a recent RTC graduate, assumed command of UDT 2

As the Summer of 1950 approached, so did big changes for UDT and SUBOPS. With the burgeoning of popularity of the Aqua-Lung, public interest increased Navy interest in underwater operations and, along with that interest, increased willingness to support research and development aimed at improving the capabilities and expanding the missions of the Navy's combat swimmers. The British Royal Navy's X-7, the submersible which had sunk the German pocket battleship TIRPITZ, was scheduled to visit Little Creek for combined operations with SUBOPS. And, although the UDT men had no foreknowledge of it, the Korean War would start in June. Ultimately, Fane and a good many UDT men would see combat action in Korea where they chalked up a remarkable record of achievements.

About a week after the North Koreans invaded South Korea, I received orders to report to USS NEWPORT NEWS (CA 148) for duty. At that time, most of us in SUBOPS were sure that we would be on our way to the Pacific within days and we were busy getting equipment into top shape. If this was to be the case, I wanted to be with them. I called the LTJG Detailer at BuPers to beg him for a year's extension of my tour of duty in UDT, to no avail.

LTJG Philip Clark relieved me as SUBOPS Platoon Officer. Subsequently, after Phil Clark left for duty in Washington, Lieutenants William Huckenpoehler (now deceased,) A.A. Moore and Robert Fay (killed in action in Vietnam in 1966,) among others served as SUBOPS officers.

There were things happening at the upper reaches of the Navy's hierarchy in Washington of which BuPers apparently wasn't aware. NEWPORT NEWS was good duty and a very valuable experience for me. But in early 1951 I was plucked off after three or four months and sent to Ft. Benning, Georgia for a four-month, joint-Services training course including, among other things, qualification in the Army's Basic Airborne Course. Al Jones, Bill Thede from a West Coast Team, and several others followed me through that course. Qualification as parachutists wasn't as yet part of UDT's training or mission but, we were selected for the training at Fort Benning precisely because we had been UDT officers. BuPers got their hooks into me again, however,. When I returned to Washington and BuPers for reassignment after I left Ft. Benning, I found myself facing the same Detailer who had refused to extend me in UDT. When he discovered, apparently for the first time, that I had been jumping out of airplanes instead of standing watches on the bridge of a combatant ship, he went ballistic and ordered me straight back to USS NEWPORT NEWS. However, thanks to a contact I had made at Ft. Benning, I was again plucked off the NEWS after several months, to report for duty elsewhere. Even so, I didn't make it to Korea until I did an interesting four-month tour there in 1953.

-----

*This is what I now remember. I know that I have left much out which should be included and have undoubtedly got the facts wrong more than once. I know that I have failed to give credit where credit is due. I apologize to those I have unintentionally short-changed. This story is simply one version of what*

*really happened. I offer it in the hope that it will stimulate others to correct my errors, fill the gaps I have left, add their recollections to an important period in the history of combat swimming and Navy Special Warfare.*

*The one thing that I do know beyond any doubt is that being associated with the men of UDT during those years, most especially being associated with the superb men of SUBOPS who took UDT underwater and, I truly believe, laid the groundwork for the future development of Navy Special Warfare, was one of the greatest privileges of my life.*

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

ORAL HISTORY OF THE MAJOR PARTICIPANTS  
IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS

INTERVIEW OF CAPTAIN BRYAN BARRETT (RN)

## PROCEEDINGS

MR. BARRETT: Hello. This is Brian Barrett. I was born in the United Kingdom, in England, in the town of Swindon.

INTERVIEWER: Brian, where did you go to school?

MR. BARRETT: After high school in the U.K., I went to Dartmouth, which is the Naval Academy in England, the equivalent of the U.S. Naval Academy, Annapolis. I joined in 1958 as a midshipman, and graduated from there. I went off to sea to finish my training in 1961.

INTERVIEWER: Since you gravitated to diving, I'm very curious as to whether you ever participated in any extracurricular sports activities while you were in school?

MR. BARRETT: I'd been interested in diving and underwater things, in general. I had always been interested in the water, in swimming and sailing, and those types of things. Those had always been principal interests of mine. It was fairly natural for me, once I was able to start the process, to qualify as a diver in the Navy.

INTERVIEWER: What influenced you to take up the Navy as a career?

MR. BARRETT: My father was in the Navy. Indeed, my great-uncle was in the Navy, so we'd always been in the service. My father was a submariner during World War II. He was a career submariner. He was at Dartmouth. It was fairly natural that I would just follow in my father's footsteps, go to Dartmouth and have a career as a naval officer.

INTERVIEWER: After leaving school, how long did you wait until you went into diving, or had dive training?

MR. BARRETT: In the Royal Navy, there are various levels of training as a diver, as is the case in the U.S. Navy. I started pretty much as soon as I could, once I finished my training, and that included my first 18 months or so at sea. I was the navigating officer of a minesweeper in the

Mediterranean in the early 1960s. Then, I qualified and went to training for what they called a 'shallow water diver,' which was really a skips diver, who did ship hull inspections, just as a sort of part-time specialization, if you like. I was a diving officer on a couple of ships before that. I then qualified full-time as a diver, and I started in 1961.

INTERVIEWER: Where did you do your dive training?

MR. BARRETT: My first lot of dive training was done in Portsmouth on what was then the *HMS Vernon*, which was sort of the home station facility for diving training in the U.K. I then did a further course, if memory serves me, in about 1962 or possibly 1963. It was in Plymouth at the Navy diving school. In those days, it was in Devonport. Then, I did a tour on an aircraft carrier as, among other things, diving officer in the Far East. I was a line officer, seaman specialist, and an 'executive officer,' as they're called in the Royal Navy. As a young lieutenant, you had the choice of specializing in a form of warfare specialization. In those days, there was a specialization called 'clearance diving,' which was a fairly small branch. Since then, it has changed slightly. I applied rather early to see if I could qualify to get a chance to specialize as a clearance diver. Indeed, I was selected to the course in 1965. It was a one-year course. They just had one entry of officers each year, and I was in the 1965 clearance diving officer's school. That was on the *HMS Vernon*.

INTERVIEWER: When you were the diving officer aboard the aircraft carrier, did you have enlisted divers for whom you had responsibility?

MR. BARRETT: Yes, absolutely. I had a team of divers. I actually had a chief petty officer, Clarence Syler, CD-1, who was the senior enlisted man working for me, running the dive team. We had, for example, search and rescue (SAR) helicopter divers who were part of the air group, and they came under my responsibility, at least as far as the diving side of their work was

concerned. We had ship diving team, as I recall. Maybe a dozen or so were like myself had other specializations, but we were also divers on the side, doing routine maintenance tasks and so forth.

INTERVIEWER: I'm very curious. Since it was a large ship that you were on, did it happen to have a small treatment chamber?

MR. BARRETT: No. We had none. Really, we would call them 'SCUBA divers.' It was self-contained, shallow water work. It wasn't anything very elaborate, from that point of view. It was clearing fowl screws and such. We kind of had a war going on with Indonesia back in the early 1960s in the Far East. We were doing hull searches and hull inspections and those types of things in Singapore, a hostile environment.

INTERVIEWER: Did you have a hard time getting the ship to shut off intakes and everything?

MR. BARRETT: That was always a battle, although we were able to do a lot of maintenance jobs in support of the engineer. Often, it involved closing off an intake from the outside lane to work on machinery inside and so on. They realized that we actually had a lot to contribute to the running of the ship. Generally, they were pretty much on our side.

INTERVIEWER: They listened to you.

MR. BARRETT: But it was an issue.

INTERVIEWER: Since your father was probably not a diver, I'm curious as to what motivated you to go into diving.

MR. BARRETT: Well, when I first joined the Navy it had been my intention to go into submarines so as to sort of follow in his footsteps. When I was still at the Naval Academy, I did a summer vacation tour. We went for a cruise for about a month or so on board one of the A-class submarines, a late World War II diesel boat. That was actually enough to persuade me that

I didn't want to do this for a career. Diving had always been something that fascinated me. As soon as I started my training in diving, I realized it was something I had a real affinity for and a real love of.

INTERVIEWER: I know that in the U.S. Navy, especially for a Naval Academy graduate to select it as his primary vocation in the Navy, diving is sometimes a very short track, as far as promotion is concerned. It's almost like cutting your throat.

MR. BARRETT: That's right. It's interesting you say that. In the Royal Navy, that was exactly the case. Indeed, I remember my father doing his utmost to dissuade me from doing it, and other senior officers said that it was not a good career move and so on. However, I'd say that in the Royal Navy, the promotion system is slightly different from the way it is in the States. In the States, the jump between commander to captain is sort of the big step. In the U.K., the big step is probably from lieutenant commander to commander, because you enter a zone in your year group. That zone is seven years long, and at each six-month interval along that zone, one or two people are picked out of your year group until after the seven years is up. If you haven't been selected by the end of the seven years, you're passed over and you'll never make commander. I entered the zone for promotion to lieutenant commander along with, I don't know, a hundred or so senior officers of my year group. I was actually the first one to be selected. I was selected at my first available shot at the age of 33, which was very young for promotion to commander. I think that vindicated my decision. I might say that my selection to commander was exactly at the time in the middle of my tour, when I was working with the U.S. Navy, and I'm sure we'll talk a little bit about that in due course.

INTERVIEWER: I'm looking back in history to see if there was something in the undersea world that the Navy felt was important enough to have some qualified people in the field of diving. I

just wonder if there was anything going on at that time that prompted your navy to say, “Well, we need some well-trained people in this field.”

MR. BARRETT: I don't think there was anything specific. I think there was always a very small number of people trickling into the branch. When I qualified in 1965 as a clearance diver, there were only four of us. In fact, eight of us started the course and four fell by the wayside. I actually graduated as the top student of the CD course of 1965. That was typical. Another year there might be three, four or five, or just very few people, because the branch was a very small one. I might say it has subsequently gotten much larger and we can talk about why that is in the course of the last twenty years. Back in those days, it was a very small specialization and still focused on explosive ordnance disposal, deep diving, and to some extent, sort of special operations work. But the sort of mainstream people undoubtedly viewed it as somewhat para-radical.

INTERVIEWER: That was kind of like the U.S. Navy.

MR. BARRETT: Yes, exactly. Generally, they had a very good reputation for getting the job done and for having good hands at work. Perhaps that was not the case in the mainstream. I like to think that I was one of the first officers, and there were many that followed, to bring the diving world back into the mainstream. In fact, I not only succeeded but also actually beat most of my generalist compatriots in the promotion stakes, with the sorts of jobs that I had. I went back onto the staff of the Naval Academy at Dartmouth as a divisional officer. I think that vindicated the decision that I made.

INTERVIEWER: Sure. Did you know John Harter at all?

MR. BARRETT: Yes. Yes, I did. I remember the name.

INTERVIEWER: I was going to say, because he was a Naval Academy graduate, had been at the Experimental Diving Unit (EDU), and was a diving officer there. Then, the Navy decided to send

him off as a commanding officer. The U.S. Navy wasn't really placing a great deal of importance on his specialized training. It was at that point that he got out of the Navy.

MR. BARRETT: Oh, sure. I remember the name. Our navy is much smaller. The jobs I had as a lieutenant and as a lieutenant commander were varied. I did a tour at the naval college at Dartmouth as a divisional officer. I was the executive officer of a destroyer. I worked at the Admiralty Underwater Weapons Research Establishment as an application officer. I had what were considered pretty good jobs. Then, I also had the tour with the U.S. Navy as an exchange officer. In fact, during my entire career as a lieutenant commander I only did a job and a half. I was picked up very early for commander.

INTERVIEWER: You were good.

MR. BARRETT: Yes, I was good. Then, having done a tour in the States, I went to our equivalent of the Pentagon, the naval staff. When I got back I was sent to a sea command and after that. I was picked up for captain. I was pretty much on the fast track.

INTERVIEWER: You mentioned having a duty here in the U.S. I noted that it was at the Experimental Diving Unit.

MR. BARRETT: Yes.

INTERVIEWER: I'm very curious to know what you thought about that tour of duty. Was it beneficial? Were there any lessons learned or any special cooperative tasks that were good for both navies?

MR. BARRETT: My naval career lasted 23 years because I chose to leave at the first available opportunity, once I was qualified for retirement, at the age of forty. I look back on my career and the absolute highlight of it was my tour with the U.S. Navy. I was asked if I wanted my name put up for that position, that job. Of course, I absolutely jumped at it immediately. I thought it was a

wonderful opportunity. At that time, I had not been involved in the sort of deep experimental saturation diving. All my diving had been as an EOD diver, in reasonably shallow water for explosive ordnance disposal. I was the executive officer of a mine hunter. I was on an operational diving team. Of course, it was an absolutely wonderful opportunity for me. I came over in 1973. It was the first time I'd ever been to the States. I'd never had actually set foot on the continent before. I traveled widely all over the Far East and in the Mediterranean and so forth, but I'd never had a chance to come to the States.

In those days, the EDU was, of course, in the Washington Navy Yard. The first year and half or so, or maybe the first two years of my tour, as I recall, was spent at the Washington Navy Yard. I was enjoying myself and enjoying the job so much that I applied to extend my time. Again, there were cries of "Oh, it's not going to be good for career. You need to get back into the mainstream." But EDU was scheduled to relocate to Panama City. I'd already had a lot of work in Panama City while I was working in Washington, and really wanted to get a chance to work at the Ocean Simulation Facility. Indeed, I was granted a third year of my tour. It was just at that time that I was surprised, and it surprised me more than anybody else, to be picked up for commander at that very early stage.

Anyway, I think it had gone on before the early 1970s, but certainly at the time that I was working at EDU, I had never come across such a close-knit international program as the one between the U.S. and the U.K., between the Royal Navy and U.S. Navy. This was how it was symbolized best for me. In 1975, when I was down at Panama City, we had the Mark I deep dive system, the HCU-1 from Norfolk. It was in Panama City, at the lab, doing what in those days was an open-sea world record dive. It was a 1,300-foot dive or something. The CO of the diving unit was a Brit on exchange, Bob Lusty. We had bunch of guys from the Admiralty Experimental

Diving Unit (AEDU) come over to provide some divers for the experiment. Their diving officer was an American, Stan Quiglensky, who was on exchange over there. We had a U.S. Navy diving medical officer who was on exchange at the AEDU.

INTERVIEWER: Who was that?

MR. BARRETT: I've actually forgotten who it was. The chief diver in the harbor clearance unit was another Brit on exchange. There we had a completely integrated structure of U.S. and Royal Navy Divers, all of whom were making a great contribution to their own navy and to the other navy. In a general sense, it was for the advancement of diving technologies and techniques. It was a really outstanding cooperative program. The superintendent of diving in the U.K. at the time was Guy Worsley, whom, of course, you know. Here in the States, it might have been Colin Jones. I've actually forgotten who was there, but the CO of the unit down in Panama City was Jack Ringleberg. The leadership of those people, who all of them were very supportive of this international exchange program under the information exchange program, was great. It was really most successful.

INTERVIEWER: I know that as far as the exchange of medical officers goes, it has just been a wonderful experience, and a major benefit to the U.S. Navy. The Royal Navy medical officers who came over here all undertook unusual research tasks and completed them.

MR. BARRETT: Yes.

INTERVIEWER: The U.S. Navy, in many cases, did not have the kind of background that some of these people had. For the U.S. Navy, it was a plus.

MR. BARRETT: I'm sure it was. Of course, we took back a huge amount of experience and knowledge. I like to think that I made a contribution to the EDU while I was there. I was the program manager, as well as a diving officer for the Ocean Simulation Facility and the saturation

diving program. Bill Spaur, our senior medical officer was running it, of course. I started actually a program for the development of a push-pull breathing system for work on the Mark II deep diving systems in San Diego. I initiated that program. I got it funded by NAVSEA and was the program manager for it both here in Washington and while I was down in Panama City. I know that I made a substantial contribution to the Mark XIV system.

INTERVIEWER: Were there any diving people in the Royal Navy who in some way influenced your career in diving, or was it all self-motivated?

MR. BARRETT: That's interesting. I think there were people who influenced me to some extent. You hit, right in the beginning, the career prospects for diving officers. To some extent, some of those who influenced most when I was young lieutenant under training were probably the people who tried to dissuade me from doing it in the first place. I'd always had a great deal of respect for some of the senior members of the diving branch. I received encouragement from some. I received a lot of encouragement as I got more involved in it and the more I read about experimental diving and saturation deep diving, the more and more I became fascinated by it. I supposed the person who encourages me and gave me the most influence was John Rawlins.

INTERVIEWER: I was going to ask you when you two met up.

MR. BARRETT: When I was first became a diver, he was a legendary figure. He was an enormously well known, well-respected and well-loved figure. You would be talking more about him, I'm sure, in your book, as a medical officer, but not as a clearance diver, or even as aviation medicine specialist for years and years. He knew every single person in the clearance diving branch. He knew every able seaman, every E-2, by nickname and who the seaman was, and where the seaman was working. He was absolutely phenomenal. He was a sort of father figure to many of us in the branch. I sort of got to know him before I became a clearance diver. Then,

once I was CD, I sort of came across him quite a lot. Indeed, I did some experimental dives with him in the chamber with him in Alverstoke at the Admiralty Experimental Diving Unit (AEDU). I'd always had a huge regard for him and still do. I think that of the people in the branch, he was probably the one that had most influence on me.

INTERVIEWER: Did you come across David Elliott?

MR. BARRETT: Yes, I did. I didn't work much with him. He was across at AEDU. I was more involved with the sort of operational Navy, so I didn't see that much of him.

INTERVIEWER: You never had duty at RNPL?

MR. BARRETT: No. I didn't. In fact, the only tour I did that was strictly in experimental diving was here in the States. Before I came here, I did about six months attached to the *HMS Vernon*, working at RMPL and AEDU, really learning a bit about saturation diving. I did a couple of saturation dives there to really to get my feet wet, as it were, so that when I came out here I'd at least have some understanding. In fact, at that time there were two U.S. officers on exchange with whom I worked. One was Quiglensky. The other was Jim Vorosmarti. I worked with Jim and Stan Quiglensky a bit.

INTERVIEWER: I forgot that Jim had duty down there.

MR. BARRETT: Yes. Jim was the medical officer there. It was about 1972 or 1973, about the time just before I came to the States.

INTERVIEWER: Did the carrier have any medical officers who had any diver medicine training?

MR. BARRETT: No. There were none whatsoever. There were a lot with aviation medicine training. We had a pretty big medical staff, as I recall, with full operating theaters and everything else. But, no, there was nobody like that there.

INTERVIEWER: They depended on you for correct diagnoses if you did have a problem?

MR. BARRETT: Oh, sure, absolutely. I had a chief petty officer clearance diver working for me. Between the two of us we managed the diving program. It went very well. We did a lot of ship support and ship maintenance during the couple years I was there.

INTERVIEWER: I can remember very well the most trying part of mine, but what was the toughest part of your diver training?

MR. BARRETT: The whole thing was an absolute nightmare. It was a bit like sort of BUDS program over here for the SEAL's. The first six weeks was meant to simply break your spirits as a diver and to stress one to the absolute limit. It was tough. Do you know the set up at Horsey Island?

INTERVIEWER: Oh, yes.

MR. BARRETT: I remember one of the weeks we were swimming and swimming and running in the mud, carrying logs around, diving or jumping off heights and heaven knows what. It was an exhausting week. In those days we were still using the pure oxygen re-breather. It got to Friday and we would get out there at the crack of dawn and swim up and down Horsey Lake, which is 2,000 yards. That was a nine and a half mile swim down and back. Then we got out, recharged our equipment, and went back in again. That was like the start before lunch, as it were. Then, you always had to run across the mud flats around the old sunken submarines. Do you remember that at Horsey?

INTERVIEWER: Yes.

MR. BARRETT: There is nothing worse than running through mud up to your thighs. It's absolute agony. Anyway, eventually, we got through the day and were sort of cursing under our breath as the chief petty officer was putting us through this nightmare. By that time it was like

four in the afternoon. We were looking forward to getting the truck, which would come out and truck us back to *Vernon*. He said, "Right, it's four. Swim back." This was from Horsey Island back to *Vernon*. We trudged out across the mud flats into the water and started to swim the whole length of Portsmouth Harbor, even with all the ships and everything around there.

INTERVIEWER: There was a ferry running across, too.

MR. BARRETT: That's right, exactly. About halfway back, there was an old aircraft carrier that was anchored by the reserve fleet. We got up to level with it and the chief petty officer was in a little Z-boat beside us. He said, "Right, there's a rope hanging down from the fantail on the quarter deck of the carrier. Climb up that to the flight deck and when you get up to the deck, look over and I'll tell you what to do next." We went forty feet up a little rope. We were exhausted by this time. Eventually, we found our way up to the flight deck.

INTERVIEWER: It was a ladder or just a rope?

MR. BARRETT: It was just a rope, a thin rope.

INTERVIEWER: Did you take your gear off? Did you have your gear on?

MR. BARRETT: We were just in fins with our rubber bags and neck rings. We were in surface gear. Then, he said, "Okay. On the flight deck, you see the gun sponson, which is three decks up. Go up to there." We went up there. He said, "Right, jump off." It was 75 feet. We did that. Then, we had to swim, as I recall, about three times around that circuit and then back to the *Vernon*. We got back at like eleven at night or something.

INTERVIEWER: Perhaps he was a masochist.

MR. BARRETT: Yes. It was the worse day of my life. We also never had anything to eat that day. We had no chance to stop for food. We were ravenously hungry and absolutely exhausted.

We'd already gone from eight to six people on the course, as I recall. Two people dropped out that day. I'll never forget that day. It was the worst day of my life from a training point of view.

I think once I got through that, though, I could get through anything. Of course, once you had six weeks of that type of stuff, at the end of it you just knew that, you and the enlisted guys who had gone through it could pretty much take on anything.

INTERVIEWER: In the U.S. Navy, when I went through diver training, we began our training with Mark V, or the hard hat. Then, we went into SCUBA gear after that. Was it the same in the RN?

MR. BARRETT: No. It wasn't, because the orientation in the U.K. had much less to do with salvage, and much more to do with EOD and special warfare. Most of our work was swimming, rather than diving, I would say. We started with an O<sub>2</sub> re-breather, which was almost like Emerson-type equipment. We used closed circuit oxygen equipment for shallow water assault work and long swims. We would start with that and then go on to mixed gas, and I don't mean oxygen-helium gas. We used enriched 60/40, 32 1/2 or 67 1/2 mixes for work to 180 feet. The work was all EOD oriented. We were also doing demolitions. We were blowing up stuff and locating mines and countermining. The orientation was much more toward the EOD, special warfare and mine warfare, rather than the diving and salvage. It was all non-magnetic equipment. It was that type of stuff.

INTERVIEWER: What areas in diving equipment, and even diving physiology, do think need support in the service?

MR. BARRETT: Unfortunately, I'm so long out of that business.

INTERVIEWER: How about looking backward?

MR. BARRETT: At the time, there were no doubts. That was at the time the Mark X system was just coming in. The whole sort of PO2 controlled systems, just having a diluent gas and the oxygen in separate containers, was in the early days. That is now, of course routinely done. I suppose the other major area that needed improvement was the whole sort of thermal-management of diver heating and inspired gas heating. When I came to the States, my orientation changed entirely for shallow water EOD, because I immediately got involved in the deep saturation work. As I said, I was the program manager for the push-pull system. That was for very deep work. There we were, looking at inspired gas heating, retrieval and reprocessing of the helium in the bell.

INTERVIEWER: What about communications?

MR. BARRETT: At that time, everything was hard wire. There were no through-water comms. I remember doing some trails with the SEAL's in Roosevelt Roads on some rather crude through-water communications. But in those days, concentration was mostly on hard wire. Again, the programs that I was involved in always had umbilicals. You were always tethered. It was no problem to have a hard wire. The problem was helium unscrambling.

INTERVIEWER: That's what I think.

MR. BARRETT: Yes. In general, most of us who had spent much time either in the bell or topside generally found that you did better without the unscrambler than with it. You had the chief diver, who had done so many saturation dives that he could understand it without any problem whatsoever. I think that generally, I didn't find the unscramblers were that much use.

INTERVIEWER: Did you have any dangerous or life-threatening experiences? I know you mentioned one experience with John Rawlins.

MR. BARRETT: Yes. John and I were in the chamber in Alverstoke. We were doing, and I don't even remember why, some 300-foot air dives in the wet port, and swimming on a swim machine. Of course, air at 300 feet is really thick to breathe. John and I were in the chamber and he'd gone down and done his half-hour on the swim machine or something and come out. I went down and did mine, and I fell unconscious. I just blacked out. It's horrible to breathe at that depth. Anyway, Rawlins pulled me out of the water and got my equipment off. I pretty well came quickly to. The only reaction I got from Rawlins, as far as sympathy went was, "That was really interesting Brian. Will you go down and see if you can do that again?"

INTERVIEWER: Good Rawlins science.

MR. BARRETT: That's right. In general, knock on wood, I wouldn't say I had many hairy diving experiences. I spent a lot of time in a Zodiac in the middle of the North Sea in the winter, diving on crashed aircraft in pretty bad weather and pretty strong tides, in very small boats. That sort of stuff was potentially hazardous. But the training and people we had on the clearance diving branch were extremely professional. My life was in their hands on many occasions, as was theirs in mine. I never had anything other than confidence in the outcome. They were very good people.

INTERVIEWER: People here in the U.S. Navy are often very pessimistic about military diving and the future of it. I'm just wondering what kind of feelings you have about that, as far as the Royal Navy is concerned.

MR. BARRETT: Again, I've been over here for so many years and I'm not closely in touch with the feelings in the RN. I think I can throw a little light on that. Back in the late 1960s in the U.K., I indeed went through a conversion from being a clearance diving officer to a mine warfare and clearance diving officer. The clearing diving branch, which was called the CD branch, became

the MCD branch. We'd always had EOD as part of our skill set. We adopted all aspects of mine warfare, mine countermeasures, mine hunting, minesweeping, and mine laying as logical things to add to the clearance diving skill. That coincided with the introduction into the Royal Navy a couple of new classes of mine countermeasure vessels. Each ship carried its own EOD and its own clearance diving team. It was absolutely logical to expand the interest of the branch and its area of responsibility to include all aspects of mine warfare. The role of diving is, in a sense, looking at in the Royal Navy's view a little bit too narrowly, because the mine warfare and clearance diving branches have extremely important roles. In fact, whereas in my day, we were qualifying two or three or four times a year, nowadays, it's a dozen a year, even though the navy is, in total, smaller. Every mine countermeasure ship normally has the commanding officer and at least one or two other clearance diving officers on board. Normally, the commander officer of the ship and one other are on board, out of a ship's four or five officers.

The role that they play is one that is not just diving, but also the other aspects of mine warfare. It gave the branch a bigger responsibility. It's not a very much recognized as a good, worthwhile career. People are being promoted to captain and commodore and so on within it, though, and it's doing very well.

INTERVIEWER: Would you recommend it to any young officer just graduating from your naval academy if he asked, "What kind of future there is for me in diving?"

MR. BARRETT: Yes, I would, very much so. It will always retain tremendous challenge, excitement and interest as a career. But I think the addition of mine warfare means that it could move back into, if you like the mainstream of naval activity, ships to command. My last job was commanding a squadron of mine countermeasures. I was the commodore of the first mine countermeasures squadron. I had ten MCM under my command. It was a perfectly normal kind

of senior officer's job. Again, I'm a little bit out of touch with it, but my understanding is that there's much less orientation toward deep diving, saturation work and experimental work than what we were involved in back in the 1970s. I guess it is for good reasons. It's not really part of their real requirements.

INTERVIEWER: There is submarine rescue, though. You do need a corps of people trained in that kind of deep diving, even though there are now rescue vessels. Sometimes they do need divers.

MR. BARRETT: Yes. I don't think one could expect a navy as small as the Royal Navy on its own to have specialists whom are simply waiting for a submarine rescue problem to arrive. It contributes to the whole international submarine rescue consortium, which includes the deep submergence rescue vehicle, Pisces Five and so forth. I do think that is justification for a diving branch. But having said that, the diving branch has oriented itself more solidly toward the field of mine warfare and clearance diving, and is certainly a very go-ahead and on-going program.

I think that a couple of people around my time and I were extremely lucky. In the late 1960s and early 1970s there were just a few of us who were lucky enough to work in the United States during the SeaLab experiments and subsequently in the experimental deep program. I was just lucky enough to be selected to do that.

INTERVIEWER: It was good timing.

MR. BARRETT: It was. It was a unique experience and one that I have always been grateful for having had the chance to do. Not many people had that chance.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

ORAL HISTORY OF THE MAJOR PARTICIPANTS  
IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS

INTERVIEW OF  
ALLEN CARL BRYSON

## PROCEEDINGS

MR. BRYSON: My name is Allen Carlyle Bryson, but I'm known as 'Carl.' My records use 'Carl.'

INTERVIEWER: Where were you born, Carl?

MR. BRYSON: I was born near Greenville, South Carolina.

INTERVIEWER: When were you born?

MR. BRYSON: On the 30th of October in 1917.

INTERVIEWER: Wow. You told me that you always wanted to go into the Navy.

MR. BRYSON: Yes. I wanted to get into the Navy from the time I was about 13 years old.

INTERVIEWER: What prompted you?

MR. BRYSON: I was big enough, but, of course, I couldn't get in the Navy at 13. In fact, I ran away from home to join the Navy when I was 13 years old.

INTERVIEWER: How come you were interested in the Navy?

MR. BRYSON: Well, I knew some people who were retired from the Navy.

INTERVIEWER: Were they family members?

MR. BRYSON: Well, they were related, yes. I thought the Navy was a real opportunity for an education, to learn a trade, and also would be a good career.

INTERVIEWER: Yes. In those days, it certainly was.

MR. BRYSON: Well, you have to remember, this was in the early 1930s, in the beginning of the Depression. Where we lived, the Depression was really a difficult time.

INTERVIEWER: Were your family farmers?

MR. BRYSON: No. All my family worked. My grandfather was a peddler. We called him 'Teamster' because he had a teaming route between Waynesville, North Carolina and Folsom,

South Carolina. We lived near Greenville. He would stop with us. From about the time I was three or four years old, I used to go on the wagon with him. That was a week's trip in and out of the mountains.

My uncle was also a peddler. He would buy fruit and produce. For example, we'd go to Georgia and buy a load of peaches and take them to North Carolina around Montreat and the Black Mountain area and sell them. We'd buy them for twenty cents a bushel on the tree. We'd pick them. We'd sell them for three or four dollars a bushel at Montreat. Apples were the same. We'd haul apples out. My family made the bulk of its money on chestnuts. But all the chestnut trees died about 1927, so that dried up the real source of income.

There were roads in and out of the mountains and they had cars in the town, but you couldn't drive a car in and out of the mountains. It was a wagon road. As soon as they built roads you could drive cars or trucks on, my uncle went into the trucking business. My grandfather never did. He stayed in the teaming business until about 1932.

INTERVIEWER: You said you had a friend who was in the Navy, and that was how you entered.

MR. BRYSON: I guess he was a distant cousin. But he retired at \$104 a month after twenty years, and a number one mechanic made \$25 a week in those days. Twenty-five dollars a week was a good income.

INTERVIEWER: That was enough to raise a family.

MR. BRYSON: Yes.

INTERVIEWER: What about your schooling? Did you finish high school?

MR. BRYSON: No. I finished grade school. I went to St. John's. I went to high school for a while in Greenville. But I had to work because I lived in town when I went to high school. I'd go

to school in the morning, get out of school at three and go work at four, and work until one in the morning. On Saturdays and Sundays, I worked from seven in the morning until one in the morning. One semester was enough for me. I quit that.

I joined the Civilian Conservation Corps (CCC). I went to Port Oglethorpe, Georgia. Oglethorpe was the home of the Sixth Cavalry Unit. They had about 2,000 horses and 4,000 men there. We were a labor battalion for months there. We worked for the sergeant or corporal, or whomever they detailed you to work for. We lived in tents and wore Army uniforms. We had a captain who was in charge of the company.

We worked there for months until we built a barracks on Lookout Mountain. Then, we moved up there and worked in a rock quarry, and we quarried stone and built roads. We built the road that's now known as 'Government Road.' It goes from Lookout Mountain Cave around the mountain to the base of the cliff. It's a good road.

INTERVIEWER: You were 17 about that time, weren't you?

MR. BRYSON: No, I was 15 then.

INTERVIEWER: You were 15?

MR. BRYSON: I had to wait until I was 17 years old to get in the Navy. I went down to Chattanooga to the recruiting station. The recruiter gave me an examination. He gave me the test and everything, and he said, "You can get in the Navy, but you have to be 17 years old. You have to have a birth certificate, and you have to go into the Navy through the nearest recruiting station to your home. I can tell you where that is if you don't know." I said, "I don't know." He said, "It's in Greenwood, South Carolina." Well, Greenwood is about 53 miles from Greenville.

When I was 17, I got a discharge from CCC, and I went home to join the Navy. I went to Greenwood. There was a fellow by the name of Luke Dirkin. His widow still lives in San Diego.

Luke was a recruiter there. He was a first class machinist. I went because I was ready to go. I thought I was going in the Navy.

When he finished the examination, he said, "Well, I'll let you know." I got the drift that I wasn't going. I said to him, "I'm ready to go." He said, "Oh, I can't send you there. I have a waiting list." I said, "How many are on the waiting list?" He said, "There are about 300." I said, "Well, how many do you send a day?" He said, "Oh, I send two or three a week." Well, you didn't have to be a mathematician to figure that out. I'd be aged before I got in the Navy. He said, "You go ahead home and get a job. I'll get you in the Navy." I went home and got a job with Scurry-Nixon riding a motorcycle. I rode a motorcycle eleven hours a day, six days a week.

INTERVIEWER: What were you doing?

MR. BRYSON: I was delivering small parts and taking orders out and things like that. I was getting receipts signed and collecting money and whatever had to be done.

INTERVIEWER: You had finished high school, though, hadn't you?

MR. BRYSON: No. I didn't finish high school. I only finished the first semester of high school. I didn't finish high school until I was 28 years old.

INTERVIEWER: Oh, wow.

MR. BRYSON: I took all kinds of exams. I took the general equivalency degree (GED) test. I passed the GED test for high school and for the first year and second years of college. But when I wanted to go to the University of Illinois, a GED didn't suffice. I had to graduate from high school, so I went to Moline High School, and I graduated along with all the kids. I had to go before the board of regents just like they did.

INTERVIEWER: You were an old man.

MR. BRYSON: Yes. I was an old man at 28 years old. I worked for Scurry-Nixon in 1934. In 1935, in July, I had a telegram come in. I was going into the Navy. My grandfather was in the hospital and dying. I loved him better than any man I ever knew, and so I wouldn't go. He died on the 6th of August. Then, I had to wait until I was 18 years old to get in the Navy. I would have been going in as a minority when I was 17. I had to wait until I was 18 years old.

I didn't get in the Navy until the 5th of January in 1936. It was an interesting thing. Luke shipped me into the Navy. He went back to sea and I went to school. I was very well read anyhow, because I read hundreds of books. We took examinations, and if you placed high on the examination, you had a chance to go to service school. I asked the chief to which service school I could go. He said, "You can go to any service school in Folsom that you want to go to."

I had just been in the hospital with mumps after I got into the Navy, and I was there 28 days. That was before they had sulfur drugs and all the magic drugs. That was the year that they had the spinal meningitis epidemic in the fleet. They used to bring these people in on one side. I was in the contagious section. They'd bring these guys in on one side and take the bodies out the other. I was going to go to pharmacy base school. I decided I didn't want to go to pharmacy base school, so I told them I wanted to go to machinist base school.

I went to machinist base school and then, I rode the USS *Henderson* from Norfolk to the west coast. I went to the USS *Medusa*, and I was in a machine shop on the *Medusa* for about six months. That was in San Pedro. Then I went to the USS *Mississippi*. The *Mississippi* had been converted or modernized in 1932 or 1933. The machine shop was beautiful. Everything was new and it had a complete shop. It had a good chief by the name of Tommy Ford. Carl Banker from Norwich was first class. They had a second class named 'Buzzy' Blue. There was a fireman in

there by the name of 'Sink.' I think his name was Sink. Anyhow, I was on the *Mississippi* for about a year and I then put in for submarine school.

INTERVIEWER: Did you do that for more pay?

MR. BRYSON: Well, Luke was a submarine man, and my company commander, when I went through recruit training, was a submarine man, and I thought I'd like to go to the submarine program. I'd gone to see the fireman. I didn't know anything about deck.

INTERVIEWER: That was ordnance, a fireman in those days.

MR. BRYSON: No. A fireman was a black gang. You were in engineering.

INTERVIEWER: Do you mean that literally?

MR. BRYSON: Yes, it was literally that way. I went aboard the USS *Barry*, the *DD-248*, and I had to make a cruise out to French Frigate Shoals, then we came into San Francisco with a '65 midshipman from the University of California. What a miserable trip that was. When I left the *Barry*, I left with two other people to go to submarine school, Poncho Black and another fellow. I don't remember his name, but Poncho was a good friend of mine.

We went into San Francisco, and we went aboard the *Henderson*. They had to ride with the passengers, but I went back with the crew. I lived in the machine shop because on the *Henderson* before, I had been in the machine shop. I spent the whole time there, and when I say the 'whole time,' you've got to remember that the *Henderson* did about six or eight knots.

We went down through the Panama Canal and up the east coast, so we were on the ship for a long time. A chief engineer asked me if I could insulate the steam valve for him. I told him sure. In those days, you'd take the asbestos and you mix it with water and get it in your nose and everything. You mixed the asbestos up and put it on the valve, and then you'd take canvass and

wrap the canvass and cut it. Then, you'd take a sail palm and needle and sew it. So, I did this, and it was a pretty neat job.

He came by and said, "Man, how about doing some other valves and piping for me?" Instead of working the machine job, I spent the whole time either playing poker or insulating the steam valves and the steam piping for him. We got into Norfolk and lay there for a while. We had a lot of experiences in Norfolk.

INTERVIEWER: Now, were they female experiences?

MR. BRYSON: No, not exactly that, but we had some interesting naval experiences there. You've got to remember that people had just come back from China, so we had some very interesting people.

INTERVIEWER: I know they developed certain characteristics over there.

MR. BRYSON: Oh, they did. You bet, they developed all kinds of characteristics. Anyhow, it was interesting, the things that happened there. Those people were just waiting to get out of the Navy. They weren't like Poncho and me. We were going to submarine school. Those people had come back from China and they were going out of the Navy. They didn't care anything about regulations. They didn't have full sea bags or anything like that. The inspections they had were fascinating. You had one guy with boondockers, and his pants would be cut off and ragged.

INTERVIEWER: I understand a lot of those guys who were over at the China stations got spoiled.

MR. BRYSON: Life was entirely different in China in those days. We had people there who were on the Yangtze River patrol. In fact, I worked for Leidenhorn, and he was on one of those riverboats up there. You probably remember the Panai River.

INTERVIEWER: Oh, yes, very well.

MR. BRYSON: The lieutenant who got shot in the neck or hit with shrapnel in the neck on the Panai was on the *Mississippi*. I was on deck the day that they decorated him for that. He stood OD watches on the *Mississippi*. He had the deck the day that I left.

Poncho and I rode the dollar line from Norfolk to New York. Then, we rode the Hartford-New Haven Railroad up to New London. Finally, we got to submarine school. When I got out of submarine school, I went to submarine diesel school. The first person I met was Luke Dirkin. He had gone back to sea and made chief, and he was an instructor.

He was doing shore duty at the submarine base. He said to me, "Carl, I don't mind shipping you in the Navy, but I'm not going to do your twenty for you." I said, "You just make like you don't know me, and everything will be fine." Luke's life was interesting. He was a fine man. He wrote letters to me from the time I went into the Navy until I was a chief on recruiting duty after the war, and Luke is still writing instructions on how to conduct myself. He said, "I never lied to you, and don't you lie to any of these boys." I said, "Luke, I don't lie to either you or them."

Anyhow, Luke's life and mine crossed because Luke put the USS *Runner* in commission. I was married at the time. That was when I was on the flag in New London. I was an instructor at the training tank. Premo Baba and Joe Charters were very close friends of mine, and they were on the R-14 with me. I went to the R-14 when I got off the USS *Squalus*. They were on the *Runner*. Galvin was on the *Squalus* with me. Luke was the chief machinist's mate on the *Runner*.

Well, I wanted to go on the *Runner*. I went down to see Luke, and I was first class at the time. Luke said, "I don't want you on here, Carl." I asked, "Why not?" He said, "You're a first class. You shouldn't be first class. You haven't even got eight years in the Navy." I asked,

“What's that got to do with it, Luke?” He said, “Well, you're going to want to go up for chief pretty soon, and I won't put you up for chief.” I asked, “What does that have to do with it?” He said, ‘Carl, there's another reason I don't want you up here. You have a good job. You've got a better job than I have. You've got a better job than the captain on this ship has. Don't get any romantic ideas about this war. This is a filthy war. Those Japanese are mad. You stay right here as long as you can. You're married. You're going to want to go up for chief. You've got a good life here. You stay right here.’”

Well, the *Runner* went out. Luke made two runs and stayed in to get his teeth out. Luke was getting along in years. He stayed in to get his teeth out, and the *Runner* went down on the third run. Of course, Premo Baba and Joe Charters and Galvin were all on the *Runner*. Luke survived the war and made lieutenant. He should have. He was a very qualified person. But it's strange how your life will intertwine. I get letters from Hilda occasionally. She's in San Diego. She and Judd were pretty good friends. When I talked to Judd, I always asked him if he would give my regards to Hilda.

INTERVIEWER: Hilda was who?

MR. BRYSON: Hilda Dirkin was Luke Dirkin's wife. I'd write to her once or twice a year.

INTERVIEWER: Maybe I'll give her a call when I get to San Diego.

MR. BRYSON: Give her a call. Well, when I came here to the submarine school, we came up here from Norfolk. Before I got out of the submarine school, they had the hurricane of 1938 here.

INTERVIEWER: I remember.

MR. BRYSON: That was a real experience. That was a hurricane, believe me. I had bought an A-model Ford. It was flooded down in the parking lot. O.B. Ross was a very good friend of mine. He's dead now. O.B. and I were on Saber Team together. We got my car floated out. We

were just pushing the car ahead of all kinds of accidents. We got the car started, and we got over to the gate, and we were in our blues, and a Marine said, "Park the car over there and get in this truck." I said, "Hey, we're going on liberty." He said, "Liberty is canceled. New London's on fire and you're in the fire party. Park that car over there and get in this truck." That's what we did.

INTERVIEWER: You did that in your blues, huh?

MR. BRYSON: We fought five of them, from that afternoon until about two in the morning, when we got relieved. Then, they herded us upstairs in the police station to keep us just in case they needed us.

INTERVIEWER: There were fires because of the hurricane?

MR. BRYSON: Oh, yes. The embers were blowing all the way over into Groton. New London didn't have any electricity for two or three weeks. They had gas service. Our bootlegger at the Manhattan was a fellow by the name of Louie. After a certain hour in New London, you couldn't get a drink, so we'd always go to the Manhattan. He still had gaslights. It was the only restaurant in New London still in business. We went down there and had some coffee after they herded us up to the police station.

When I got out of school, I went to the R-4. There were six R-boats that never went out of commission. The rest of them were out of commission, along with the O-boats. I went to the R-4 and thought, "This is great, because I've got leave." I went home. I was home on leave. I was home two days and got a telegram to come back to the ship.

INTERVIEWER: That would have been the first of 1939.

MR. BRYSON: It was the first of 1939, yes. I had taken the examination for second class. When I went there, second class came through. I made second class. When the ship was commissioned, I was a second class machinist's mate. When I first went into the Navy, going to school held me

up because you didn't get rated then in those days. There was a time that when you graduated from that school, you graduated as a second class petty officer. But that was not the case while I was there. It held me up a little bit on rates, but I never missed a rate after that. I missed one quarter, but I didn't miss it on the examination. I missed it because of the difference of opinion between the officer and myself.

When I got up there to put the *Squalus* into commission, we had a couple of guys from my submarine school class. Casey was a close friend of mine. Casey and I were stationed in the forward engine room. Admiral Doyle had been in the Navy yard as a member of the staff that was constructing submarines. When the *Squalus* went into commission, they assigned him to it as the executive officer and the engineer officer. Ensign Patterson was a junior officer in the engineering department.

Anyhow, I did all the ordering of engineering stores of spare parts. In effect, I was the engineer officer's storekeeper. Not wanting to waste any of my time, my dive station was in the forward battery, which turned out to be really fortunate for me because nobody got out of the forward engine room.

INTERVIEWER: Yes. That's true.

MR. BRYSON: I don't remember how many test dives we really did, but historically, we were on our 19th test dive. We were loaded with spare parts and supplies. We were ready to leave. The USS *Sculpin* was a week ahead of us. It would have been our last sea operation before shoving off on our shakedown cruise. That year, the World's Fair was held in New York and San Francisco. Were going to make it to both World Fairs. Everybody was happy about that. Needless to say, we didn't make it to either one.

The day that we went out, we had not been in to the base. We had been anchored off the point. On the weekend, Teeter Savage was hit in the eye with a baseball. We were having a softball game and it hit him in the eye. He was in the hospital, and he was a first-class machinist, so he didn't go out on the ship.

That morning, O'Hara came aboard. That was his first trip out on a submarine, and less than an hour later, it was sunk. We got off the shoals on a dive. I had the sound powered phones on, and I heard Casey in the forward engine room say, "Take her up, the induction's open." The induction valve was a big 36-inch, mushroom-type valve. We had a ship's air induction which was, I think, 24 inches in diameter, also. But with the engine air induction, the air came down a huge pipe and went down outside the surface, and then outside the hull. At each engine room you had a flapper valve that was operated by a worm and sector mechanism. You had to stand right under where the air was coming in to shut the valve.

INTERVIEWER: You had to do that mechanically.

MR. BRYSON: Yes, it was done mechanically. It took about three and a half minutes to shut down because we weren't too smart. You have to remember, most of the people came off of R and S boats, and everybody had to study the boat. School of the boat was a daily operation. All in all, there was a shortage of people who knew fleet-type submarines.

INTERVIEWER: That was a state-of-the-art boat at the time.

MR. BRYSON: Oh, you bet it was. If we had been smart we would have had the packing oiled and loosened up so that he could spin that valve. As a result of the sinking, they put a trip mechanism on those valves, and it probably saved some ships after that because you just had to trip that. They had a big lever that was about three feet long. You tripped it and the valve would

fall shut. Then, you took a level and dogged it. That dogged that hull flapper valve. That was done on all the ships.

INTERVIEWER: Now, Judd told me that a friend of his brother's was on another boat. I don't know if it was the *Sculpin* or not, but they had that same problem.

MR. BRYSON: You're talking about Gainer. Gainer's brother was on a boat that had a similar incident occur. It had happened prior to the *Squalus*' accident. You have to remember that information flows very slowly in a bureaucracy, and the Navy was a bureaucracy. Hindsight is really good. I can go back into history of my experiences in the Navy and just point out mistake after mistake by people in the bureaucracy, and those mistakes have domino effects. You put out an ALNAV to do something and it was done throughout the Navy. Everybody did it. If it was wrong, everybody did it wrong. Information never got to the right people. Even if the information got to the right people, if they don't take any action on it, the information was useless. You can know something, but what good does it do if you don't take action on it?

INTERVIEWER: You said it took three minutes to close that valve, but you were on a less than sixty-second dive.

MR. BRYSON: The thing was that you had to stand right under the water that was coming in. If air was coming in, it took three and a half minutes to shut it because it was ----. Casey was standing under the water. When the ship was brought up, his body was still standing over by that valve.

I heard Casey say, "Take her up. The induction's open." That was the last thing I heard. By then, the water was coming in. Everything happened very suddenly. The engine air induction, the air and the water, went to the engine room. On a ship's air induction, the air went through the ship's ventilation system. There were two lines going through each bulkhead, forward to the

torpedo room, and then to each compartment. We got a shot of water and air. You had bulkhead flapper valves on the ventilation system. Of course, when that happened, the first thing we did was shut the bulkhead flappers.

It was obvious that we were in trouble. McLees was standing in the battery well. I remember it so well. That means that it was up over his knees. He was standing on the walk in the battery well. He climbed out of the battery well and went forward to the torpedo room door. When he shut the door, he was in the torpedo room. I was in the compartment with Jacobs and the two Filipino mess boys, Galvin and Elvito. Galvin and Elvito spoke poor English, and jiminy crickets, when they got excited, they hardly spoke English at all. Jacobs was in there. He was the radioman. Later, Jacobs committed suicide.

INTERVIEWER: I wonder why?

MR. BRYSON: I don't know. Luke Gainer was in there with me. Luke was a well-qualified submarine man. He was the chief electrician's mate. He went down into the battery. I think Luke said they were pulling several thousand amps or something like that. Anyhow, they were putting such a load on the battery that the heat from the cells was making fire sputter from the heat. Luke knew that we were on the verge of an explosion. He went back aft to throw the battery disconnect switches, which were against the bulkhead in the aft. It was dark down there. He went down and threw the first battery disconnect switch. The arc carried the circuit, so it didn't break the circuit. When he threw the second one, it broke the circuit. I wouldn't have known to do it. It was a good thing Gainer was in there, because if he hadn't done that, there wouldn't have been any survivors to rescue.

INTERVIEWER: It would have blown up.

MR. BRYSON: Yes. It affected his eyes. Gainer was blind when he died.

INTERVIEWER: It was a big arc.

MR. BRYSON: Yes. It was the arc from the battery disconnect switches when he threw the switches to open the circuit. Anyhow, he did that. We had fresh water coming in, and we stopped that. We didn't know where the water was coming from, but there was salt water getting into the battery compartment. When salt water mixes with sulfuric acid, you have chlorine gas. We had a little chlorine gas in the lower compartment. We dug the hatch down too, but nobody knew where the water was coming from. Afterward, we found that there was a tiny capillary tube that connected the after battery to the forward battery, and there was no valve in that. That was another issue that came out of the accident.

We asked the captain if we could go in the forward torpedo room, and he said, "Yes. Go ahead in." Well, we went up, and they wouldn't open the door for us. We finally prevailed, got them to open the door, and we went in the forward torpedo room. We stayed in the forward torpedo room until the first bell. It was very cold and very dark. It was about 28 degrees in there. Wherever there was condensation, there was ice. Everybody was being very still to conserve oxygen. We didn't have oxygen on the boat in those days like they have today. We had a couple cylinders of oxygen and a bunch of CO<sub>2</sub> absorbent. We were in there. We couldn't hear anything. We had released the forward buoy with the telephone in it, which was a marker buoy that meant a submarine is sunk here. We heard the *Sculpin*'s screws. That was the first sound we heard. We were sending up smoke signals also. We had a signal gun. They spotted one of the smoke flares, and they went over and picked up the buoy on the deck to the submarine. That buoy cable didn't make a good anchor chain. The captain on the *Sculpin* and Naquin had time to exchange a few words, and then the cable snapped.

We were without communication until the USS *Wandank* came. They had an oscillator. They could send signals that we picked up because we could hear the oscillator. But for us to send a signal that they could hear, we had to pound on the hull with a hammer. It was one stroke for a dot and two for a dash. Well, that was rather tiring, and they couldn't understand some of the signals, and we had to send it over again.

To make a long story short, it was a poor communication set-up. I don't know what all the communications were. The captain, I think, kept a log of it. Finally, the USS *Falcon* came up from New London. It was a steamship. They were doing maintenance work. They put the engine and everything back together and got underway, and they got up to where we were.

INTERVIEWER: They came with the bell.

MR. BRYSON: They came with the bell. The first diver down was Savitsky. Somebody had hooked into the ship with an anchor or something. It had a cable on it. It dragged into the ship. When Savitsky came down, he came down the cable and landed his feet right on the deck, within six feet of the hatch. Savitsky was a huge man, a marvelous diver and marvelous person. He landed there. Preseco and I went up into the trunk, and we could hear him talking. We could understand what he was saying because it was so quiet down there.

INTERVIEWER: I understand he was cussing, too.

MR. BRYSON: I never heard him cussing. Savitsky was not much of a profanity man. He was a very, very clean person.

INTERVIEWER: Didn't he get a Congressional Medal?

MR. BRYSON: No. He got a Navy Cross. But he was so huge that his number three suit, which was the largest suit, had to have the arms on it cut and an extension in the arm put on so that he could work. They couldn't do anything about his feet because that was a difficult thing to patch

into, so his toes were always drawn up. Anyhow, it was a good thing he came down because he was a great diver. The cable from the marker buoy had fallen down on deck when it was parted, and it was over the hatch. Well, he had the presence of mind to take that cable and get it clear of the hatch because the bell had a seat ---- on the bell seat, around the hatch. Then, he attached the down-haul cable, and to me, that was the Savitsky's greatest feat in the rescue.

INTERVIEWER: You were down at 240 feet.

MR. BRYSON: Yes.

INTERVIEWER: Visibility must have been almost zero.

MR. BRYSON: I don't think that was the case at 240 feet. It was dark there, of course. I don't think that, at that latitude and at that time of year, during the daytime, the visibility was that bad.

INTERVIEWER: It was May.

MR. BRYSON: Yes. It was the latter part of May, and the daylight hours were not so dark that he couldn't see down there. When Lesker made the dive on the 09, that was 470 feet or so.

That's dark. Of course, when the *Thresher* went down, she was down 8700 feet. That's very dark.

You have to have a light. But Savitsky did a really good job. On the first bell trip, Mr. Nichols was in the forward torpedo room. He went up because the captain wanted an officer representative on the topside. Mr. Nichols was chosen to go up.

INTERVIEWER: He wasn't the executive officer.

MR. BRYSON: He was the gunnery officer. Doyle was a lieutenant. He was the executive officer and the battery officer.

INTERVIEWER: I'm surprised Doyle didn't go up first.

MR. BRYSON: As far as I know, when the first bell trip went off, Doyle was still in the control room. When the bell got there, it brought down a five-gallon milk thing full of soup, and they

ventilated the best they could while they were there. I think McLees went up on the first bell trip. I don't know why he went up on the first bell trip. I didn't expect to go up on the first one.

After the first bell trip, the captain had been in and out of the compartment. They took lungs back there so that they didn't have to breathe the air. After the first bell trip, everybody in the control room came up into the forward torpedo room.

INTERVIEWER: How many hours were you down before the first bell?

MR. BRYSON: Well, we went down at about 8:30 in the morning. Early the next afternoon was when I think the first bell trip occurred.

INTERVIEWER: It was about 30 hours, then.

MR. BRYSON: I would say, yes, it was about that. I came up on the fourth bell trip. I think we were in the bell for about three hours or so because the downhaul cable jammed. I think it was after midnight. Of course, I had been there all that time. We were frozen. Everybody was frozen. I remember it very well. I was watching Mike Coloski in the lower compartment of the bell. When he put the downhaul cable over the ship, he didn't pull the faring over it. But I wasn't bell operator. I didn't say anything about that. Anyway, we dropped a few feet and the downhaul cable jammed. They couldn't free it, so they sent a man down and finally cut the downhaul cable.

INTERVIEWER: That was the last trip, and Naquin was with you.

MR. BRYSON: Yes.

INTERVIEWER: You were on the last bell trip.

MR. BRYSON: Yes. Cravens, Pierce, Persico, Naquin were on it, too. I think eight or nine of us were in the last bell trip. They started to haul the bell up and it had negative buoyancy. The bell had positive buoyancy until the downhaul cable jammed. To avoid it popping up when they were going to cut the cable, they flooded it a little bit. We had a little negative buoyancy, so they

started to haul us up with the up-haul cable. They got it up a few feet found that several strands of the nine-strand cable had parted, so they dropped us back down in the mud. We were sitting down there waiting for everybody to decide what to do. They were afraid to blow the lower compartment to give us positive buoyancy, because we would have shot up like a rocket and hit the ship, maybe even sinking the ship.

Finally, they decided they would blow the lower compartment a little bit. They blew it, and they blew it a little more. They kept pulling it by hand up there to see if they could pull the bell up. They blew the lower compartment a little bit more until they could pull it by hand. If it had parted that cable, it would have parted the air hose and the ---- cable, and that would have been the end of the people in the bell. They were pulling on it by hand. Of course, you couldn't keep adjusting the lower compartment. As we went up, the pressure around it decreased and the air inside expanded, so we got lighter and lighter until we got up to about 150 feet. Then, we went up like a rocket. I mean, zip, we were on the surface. With the great speed of air expansion, it was just like a rocket. We shot right up to the surface.

INTERVIEWER: The story I understood was that the cable was still attached to the *Squalus* on the fourth trip. You started out, and you got jammed, and then they cut that cable. But I didn't know they lowered you back down under the blue mud.

MR. BRYSON: They did. When they started to haul us up and found the up-haul cable was almost parted, they had to lower us down because if that parted, that was the end.

INTERVIEWER: They brought down another cable?

MR. BRYSON: They tried to send down another cable, but that got fouled, and they didn't do that.

INTERVIEWER: You were sort of a cork floating down.

MR. BRYSON: No. We were sitting on the bottom. We swung around a little bit when they first cut the cable.

INTERVIEWER: Then, they lowered you down to the bottom.

MR. BRYSON: Yes. When they decided that they would cut the cable, they had to adjust the balance so that we had negative buoyancy instead of positive.

INTERVIEWER: That was the downhaul cable.

MR. BRYSON: Yes.

INTERVIEWER: I didn't realize that part of the story. The communications in the boat were so that every compartment could hear everything? Was there a loud speaker in each compartment?

MR. BRYSON: There was a public address (PA) system. I was the person in the forward battery. They had the sound telephone call. Casey was the person in the forward engine room with a sound ---- telephone call.

INTERVIEWER: Even if people didn't have earphones, they had speakers in every compartment. You could hear everything.

MR. BRYSON: Oh, yes. There was the PA system. I don't know what you mean by 'hear everything,' though.

INTERVIEWER: In other words, I thought maybe they had this talker between the compartments.

MR. BRYSON: No. We had a PA system in the control room, and you could hear the signals. We passed the word over the PA system, but we didn't have any electricity. After he threw the battery disconnect switch, there was no electricity, so we didn't have any communication like that. The sound ---- forward was all that we had.

INTERVIEWER: The instant that you discovered that your compartment was flooding, you still had electricity.

MR. BRYSON: Yes.

INTERVIEWER: I guess you had battle lanterns later.

MR. BRYSON: We had battle lanterns, yes. But the period that we had electricity, after we knew we were sinking, you've got to remember, we are talking about seconds. We're not talking about minutes. Things happen very rapidly in a situation like that.

INTERVIEWER: Judd told me you had no sense of falling. The boat took about a 45-degree angle.

MR. BRYSON: There was no sensation when the stern went down.

INTERVIEWER: It just sort of slowly sunk down.

MR. BRYSON: You didn't have a sensation of anything, except feeling the upward angle becoming acute. That was the sensation. The boat went down by the stern.

INTERVIEWER: I understand that you almost never felt it going into the mud.

MR. BRYSON: If we did, I didn't notice it. I had other things on my mind at that time.

INTERVIEWER: Was hanging on going through your mind?

MR. BRYSON: No I was thinking about trying to keep the water from coming in things like that.

INTERVIEWER: Was there any panic at all?

MR. BRYSON: If you mean if there was any excitement, yes, there was a lot of excitement. If you mean hysteria, I don't remember any hysteria, though a lot of people may have felt hysterical. It was a very, very exciting moment. If you practice for emergencies, which is what people are supposed to do on a submarine, when the emergency occurs, and this was obviously an emergency, things happen very rapidly. Everybody wants to know what you were thinking.

Well, you didn't think about anything except how to solve the problem and see if there was another problem and then solve that.

INTERVIEWER: It was the immediate problem that was going through your head.

MR. BRYSON: You bet.

INTERVIEWER: I understand during the entire time you were down there, Naquin had to just lay down and quit breathing as much as possible.

MR. BRYSON: He not only quit breathing as much as possible, but it was very cold, and people huddled together to keep warm. Body heat was very important to conserve. Also, the old man discouraged conversation and any kind of movement that would burn oxygen. The air was getting very, very bad. In fact, when we left there, the air was terrible. We had put out all the soda lime, which is a carbon dioxide absorber. We had all the oxygen drained into the compartment. But after the people came up from the control room, the air got progressively worse.

INTERVIEWER: Well, Judd said one of the fellows opened the chart drawers and threw soda lime all over the place.

MR. BRYSON: They put soda lime wherever they could.

INTERVIEWER: I understand Naquin stayed completely in control the entire time.

MR. BRYSON: I thought he did. He was a remarkably fine individual. I was the bridge talker and maneuvering, so I was close to the old man. I knew the old man very well. I don't mean socially. I repeated on the phones every order that he gave because when I was bridge talker, I wore the phones on the bridge. If he gave a signal, I repeated that signal to the control room.

I know that once, I got the signals wrong. When you came in to make a landing in Portsmouth, depending on the tide, you had to drive yourself in there. I gave a wrong signal. The

old man held back on one and all ahead on the other. I got it reversed. Then, he said, "All stop." I told them, "All stop." Then, he gave me the signal again, and I gave it correctly that time. He never said anything to me about it. That was the kind of person he was.

INTERVIEWER: Jim Dothe, up in Portsmouth, told me that he has Naquin's log.

MR. BRYSON: Yes. The skipper told me that he was going to give it to Dothe after the 50th anniversary up there.

INTERVIEWER: He did.

MR. BRYSON: He kept it all those years. He gave it to him for the reunion. I think Jim missed a lot of memorabilia from the boat when Fanny Gerber died. Before she died, Fanny told me that she was going to give me all her stuff. She had a lot. She told me that she was going to give it to me, but I didn't go back to Portsmouth that often. When I had two children, I took two of my children by there to see Fanny. I loved Fanny. She was a lovely lady.

INTERVIEWER: What happened?

MR. BRYSON: Fanny and Hank Gerber ran the club cafe. That was where a lot of the guys hung out when they were off the boat. I always hung out there. I thought they were wonderful. Fanny used to plan our weekend parties. In the winter, Jim Trebentan made his camp available. Jim used to go with us. Fanny would make all the arrangements, and we'd go up on Saturday and spend Sunday up there.

INTERVIEWER: What happened to all the *Squalus* artifacts?

MR. BRYSON: Well, a lot of them are around in different places. Different people have different things. I remember that life ring so well, because when you set the watch, you always brought the life ring out hanging up. That was one of the checks that you did. I was a speaker for the northeast regional convention many years ago. Swede Larson and I worked for an electric

boat company after we got out of the Navy. Swede came in with this big bag. After the speech, he said, "Carl, we want you to have this." I couldn't figure out what in the world he was giving me. He took that life ring out, and I immediately recognized it. This guy had that life ring all those years up there in Portsmouth. He decided to give me the life ring because I was the guest speaker.

I'll tell you another thing. Harold Lancaster and I served together in the tank. Harold was on the USS *Falcon* when the *Squalus* went down. Harold sent me a number of things, including lots of pictures. He sent me an airdog off of one of the portholes on the *Squalus*. He had that all those years. He just sent that to me four or five years ago. He sent me a little document with pictures, showing me from where he got the airdog.

The bell is down in one of the fleet naval reserve places. I have a letter from the skipper's daughter, Lorraine Naquin-Tyler. She sent me a letter with a picture of them by the bell. Captain Naquin's son, Chris, is a retired Navy captain. INTERVIEWER: The original bell is still in existence, then.

MR. BRYSON: Yes. It's in a fleet reserve place down in Maryland, I think. It's in Maryland or Pennsylvania. I don't recall.

INTERVIEWER: I understand Captain Naquin had to go down below the floor plates.

MR. BRYSON: Well, the deck and the forward battery made up the communication area. That was where you walked back and forth. When you opened a hatch, you went down the walkway, and in the battery compartment, there were batteries all over. You had a crawlway. There was only two and a half or three feet of clear crawling space to get around the battery. That was what Gainer was doing there. He was up there because we were going to be pulling the load, and he was going to take the gravities on the battery. That was what Jacobs was doing there. He was the

recorder helping. McLees was supposed to be Gainer's helper, as well. When Gainer started looking for McLees, McLees was in the forward torpedo room. He was stuck with me, and I wasn't too smart.

The only assistance that Luke had was from me. I'd been on the R-4 and I had been studying the book therefor a little while, but I wasn't knowledgeable. I wasn't qualified. I don't know if Jacobs was qualified or not. McLees was a qualified submarine man. He was in absentia, as far as we were concerned. He was in the forward torpedo room. Galvin and Elvito would do anything you told them, but they didn't know what to do.

INTERVIEWER: Yes. Judd was the second electrician.

MR. BRYSON: He was a first class electrician's mate, but he was in the control room.

INTERVIEWER: He was in the control room, where he was supposed to be. Judd told me that Naquin wanted Gainer to get a medal, a Navy Cross or something.

MR. BRYSON: Well, I don't know anything about that.

INTERVIEWER: But the admiral said, "Well, that was his job."

MR. BRYSON: That is something that I don't know anything about.

INTERVIEWER: That's all I know. Last night, you said you felt that Gainer was upset or ticked off.

MR. BRYSON: No. I don't think he was ticked off, but he was bitter, and I think he was justifiably so.

INTERVIEWER: Why was he bitter?

MR. BRYSON: He was bitter because of the lack of information, the way in which we lost the ship, the similarity between the problem we encountered and the one his brother had encountered previously, and the lack of communication and getting that information through. Also, Gainer's

loss of eyesight, I think, was directly traceable to his experience in throwing the disconnect switches.

INTERVIEWER: You said he died blind.

MR. BRYSON: Yes. He was essentially blind. This was told to me. I have a couple of Gainer's letters in my possession, official letters. First, I have his official statement at the Board of Inquiry and second, I have the statement he submitted voluntarily. It's quite lengthy and quite detailed. It describes not only the situation in which he was involved on the ship, but also his conclusions and analysis of the lack of communication.

INTERVIEWER: I would assume you would give copies of that to the Portsmouth Museum.

MR. BRYSON: I would not.

INTERVIEWER: Why?

MR. BRYSON: Because the way I came into possession of them, I would not give copies out. I intend to keep those. When I finish writing, I intend to use them as my authentication of what I have to say. I'm writing a book. I don't know if I'll ever finish it or not, but I'm in the first draft now.

INTERVIEWER: Is it a book about your Navy experiences?

MR. BRYSON: Among other things, yes. That was a notable experience in the Navy for me. I had a number of experiences. You don't go through the Navy and have just one experience.

INTERVIEWER: No, especially with a war coming.

MR. BRYSON: Well, I had experiences both before and after the war. I had a lot of experiences in the Navy.

INTERVIEWER: Did you get involved in the salvaging of the ship?

MR. BRYSON: Oh, yes. I was in the hose gang. After we came up, I was frozen. I went in the recompression chamber, not to be decompressed, but because I was cold. Everybody else had gone into the hospital, or at least the first three bell-loads. They kept those of us on the fourth bell trip on the ship until the next morning. They put hot towels on our feet. In about a minute, the towels got cold and they put on more hot towels.

The next morning, everybody who was in the fourth bell cup went aboard the USS *Harriet Lane*, a Coast Guard cutter, and we went to the hospital. I didn't want to go to the hospital. I wanted to go to the Club Café or some other place, but we went to the hospital anyhow. I felt good after I got warmed up and got a bite to eat.

INTERVIEWER: You were still young, too.

MR. BRYSON: Oh, sure. Then, during the salvaging, I worked in the hose gang.

INTERVIEWER: Do you mean after the *Squalus* was brought in?

MR. BRYSON: No. I mean during the salvaging of it. I think there were 28 or so hoses. The hoses had to be made up, and they had to be hooked up by the diver, and then they had to be buoyed off and marked and everything. Then, when they got ready to ----, the hoses from the ship and those that were buoyed off had to be hooked up properly. That was the gang that I worked in. We handled the hoses. I worked out of a boat. I worked on a barge. They had barges alongside. I worked throughout the salvage.

INTERVIEWER: It was three months.

MR. BRYSON: Yes, it was about that long. There were lots and lots of people and very few places to berth. One time, I was berthed aboard the USS *Sacramento*. It had been out in China for years and had come to be decommissioned. They didn't have much coal on it. They had B

and C bunkers, and they had coal only on C bunkers. I was wheelbarrowing the coal from C bunkers across A and B bunkers so that the smart guy could shove it into the firebox.

INTERVIEWER: That was after you came out of the *Squalus*.

MR. BRYSON: Yes.

INTERVIEWER: Naquin told Maderes that he was going to go out.

MR. BRYSON: We didn't know if we were going to have a bell or not. We had planned an escape. The first person to go out had to release a buoy up to the surface, flood the compartment, open the door, and put the line out that had the buoy on it and let it up to the surface. Then, he had to quickly make it clear of the door so that you could open and shut the door. When he had that done, we would make the escape.

The captain selected the Greek because when you see the Greek today, he's a tiny person, but he used to be a powerful man. He was short but very powerful and was a well-qualified person. He was a third-class torpedoman on the ship. But as the Greek said, he made second class so many times that it was a very familiar change.

INTERVIEWER: He kept losing it, huh?

MR. BRYSON: Yes. Anyhow, he was the one who was selected as most capable to do that. I might add that I felt very secure in that because I thought he was most capable, too. But we had grease and everything because of the cold water. All the procedures were understood. The only problem was that, later, the oxygen supply was in question. You had to charge that lung with oxygen.

If we had needed to make the escape and launch, somebody may have made it, but that's academic. It's my personal opinion that it would have been a miracle if anybody had made it. I'm

not saying it would have been impossible, because there was a history of a Greek going down 256 feet and slipping an anchor.

INTERVIEWER: Maderes did that?

MR. BRYSON: No, not *the* Greek, *a* Greek. By the way, Greek Maderes was not a Greek. He was Portuguese. His nickname was Greek.

INTERVIEWER: I understand that in submarines, everybody seemed to have a nickname.

MR. BRYSON: A lot of people had nicknames.

INTERVIEWER: What was yours?

MR. BRYSON: Nobody ever called me by a nickname. They called me 'Bryson' or 'Carl.' If they knew me well, they'd call me 'Carl.'

INTERVIEWER: When the *Squalus* was brought into dry dock, did you get to work on it at all?

MR. BRYSON: Yes. I had to stay there. We had to take everything out. We were fully loaded with engineering supplies and engineering spare parts. We had to take all that stuff off the ship, lay it out in a warehouse, and tag it for the Board of Inspection and Survey to come and survey.

INTERVIEWER: Well, Judd told me it kind of ticked him off that guys were just standing on the dock and weren't doing anything, and you guys who had gone down and come out were doing a lot of the work.

MR. BRYSON: I was never conscious of that.

INTERVIEWER: He also said that in the aft three compartments, the two engine rooms and the torpedo room, bodies were still there after three months.

MR. BRYSON: Yes, sure, all the bodies were still there, except Thompson's.

INTERVIEWER: He got jammed in there.

MR. BRYSON: Well, Thompson's body was never found.

INTERVIEWER: The water was so cold that it preserved the bodies pretty well.

MR. BRYSON: Yes, they said that. They had some of the crew help with the bodies. I was not involved with that.

INTERVIEWER: I thought it was pharmacist mates that had to come down and do that.

MR. BRYSON: I was an escort to Copperhill, Tennessee with Elvin Deal's body because I was the best man at his wedding. My family functioned down in that section. I went with his body to his home. His wife was there when I got there.

INTERVIEWER: That was pretty rough, obviously.

MR. BRYSON: It was rough on his family. They were having a bad situation there in those days anyhow. People were carrying guns and shotguns and everything because it was a copper mining area, and they were having a lot of union trouble.

INTERVIEWER: Do you think we've covered everything?

MR. BRYSON: Well, I think so. When I took Savitsky's job at the tank and the 09 went down, I was in the shower. I had just finished a class. The guy came in and said, "Get your toilet articles and some dungarees together and get on the USS *Chewing*. You're going to Portsmouth." I said, "I'm not getting on the *Chewing*," because Tutt was the master diver on it, and I didn't care much for him or his brother, either. He said, "the 09 is down, the *Falcon* is in a four point over the 09, and Captain McKinsey asked for you by name, so you're going." Ed Baker, three other guys and I went aboard the *Chewing*. We worked all night. We made up three sets of lifeline air hoses out of new hose, put tests on them and stopped them off. We made one of them with three lines.

Lifeline air hoses and electric cables that were for electrically heated underwear.

We got up there the next morning and were transferred to the *Falcon* with our gear.

There were two or three divers who went down. It was an overcast day. I dressed and tended

without a shirt on, and I got blistered. Metzger made the dive with the heated underwear on. But when he got down, they didn't have enough electric cables. When he got to the bottom, he didn't have any electricity in his electrically heated underwear. He was the one who got down to the boat. They decided there was nothing to be done. They wouldn't try to salvage the boat. That was the end of the operation, when he made his report.

INTERVIEWER: I didn't know there was another ship that went down.

MR. BRYSON: Oh, yes. The 09 went down within five miles of where we were, but they were in 470 feet of water.

INTERVIEWER: What caused it to go down?

MR. BRYSON: Well, there's speculation on that. The 09 had been in Philadelphia for twenty years, and they put it in commission. I figured it was rusted tanks. Maybe a guy hit the bypass a little too heavy with HB air, or maybe the tank just caved in or whatever. It shouldn't have been in deep water that deep, not for testing. Those old boats were all in bad shape. They were rusty.

INTERVIEWER: You said you were working at the tank.

MR. BRYSON: I was an instructor at the submarine escape training tank.

INTERVIEWER: Was that over the tower?

MR. BRYSON: Yes.

INTERVIEWER: That's the famous tower.

MR. BRYSON: Yes. Then, when the *Thresher* went down in 1963, I was the engineer on the USS *Sunbird*. We were standing in from a two-week operation. We got the message. We turned around and it was a 19-hour trip. The USS *Atlantis* and the USS *Skylark* were up there. The seas were building up, and debris was coming up from the *Thresher*. I had the deck mid-watch. If you saw something and you went down, you lost it in the wash, so I told the skipper, "Let's go

upwind and drift through.” We drifted through and picked up lots of personal gear and stuff like that from the *Thresher*.

INTERVIEWER: There's a movie of which I have a copy. It's called *Submarine SI* and was made in New London. Wayne Morris is in it. Were you involved with any of that?

MR. BRYSON: No. I was involved with the movie *Crash Dive*. Jimmy Gleason played the chief of the boat. Tyrone Power was in it. It was made on the USS *Marlin*. I had a picture of Tyrone Power and the crew at the top of the tank. I gave them a copy of that picture up at the submarine escape place. They have a new submarine escape place. It's named after him. It is called ‘Morrison Hall.’ His son gave the dedication address. I went and gave them a copy of that picture with Tyrone Power. That's my claim to fame.

INTERVIEWER: Did you happen to see that movie, *Submarine SI*?

MR. BRYSON: Years ago, I think I saw it. I don't even remember it.

INTERVIEWER: I was just wandering how accurate it is.

MR. BRYSON: I think that was made on the USS *Dolphin*. Denarksy was on that boat when they made that film. He was a second classman on the 14 boat with me.

(Whereupon, the INTERVIEW was concluded.)

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF CHARLES W. BEIL

Kensington, Maryland

Thursday, September 4, 2003

## PROCEEDINGS

EM1 BEIL: I'm EM1 Charles W. Beil. I've been at Naval Special Clearance (NCS) Team One for about a year.

INTERVIEWER: Where did you come from?

EM1 BEIL: I came from SEAL Team One.

INTERVIEWER: Was that here, in Coronado?

EM1 BEIL: Yes.

INTERVIEWER: You made Special Clearance Team One's first operational funding, to Operation Iraqi Freedom, right?

EM1 BEIL: That's correct.

INTERVIEWER: What was your assignment?

EM1 BEIL: Basically, our mission was to go ahead and defeat mines in the water. Our operating depth was around forty feet.

INTERVIEWER: What dive equipment did you use?

EM1 BEIL: We used the Viper rig.

INTERVIEWER: Was that the Viper VSW?

EM1 BEIL: Yes.

INTERVIEWER: How do you like that rig?

EM1 BEIL: I actually enjoy it quite a bit. There is only really one drawback on the rig and that's the flow rate. Basically, it feeds you 4.5 liters a minute, and it's just too much. It's too much because if you are a combat diver, which is my background, you're always moving, you're always kicking out. You try to make a timeline to meet your goal. It's a little different.

INTERVIEWER: What exactly is different, the civil I-5?

EM1 BEIL: Oh, yes, absolutely. Comparing the Viper to Drager, I prefer the Viper. I prefer the configuration, the way it sits on the back and everything. I find it a lot more comfortable in the water, period. It's just that flow rate, in particular, that I don't like. It's just pumping out so much

that you get the chipmunk cheeks. You're off-gassing terribly. That is about the only drawback. My understanding is that people are trying to work that out to get it turned down.

INTERVIEWER: Yes. I think they are at the experimental level, in fact. You deployed to Operation Iraqi Freedom with Gunnery Sergeant Doss, on his dive platoon?

EM1 BEIL: That's correct.

INTERVIEWER: What did you do?

EM1 BEIL: We went in. Initially, we were prepared to occupy Umm Qasr for four days. That was what we were taking in, everything necessary for four days. We were taking all the bullets, food and water that we would need for four days.

After that, tasking was extended considerably. We ended up being there for just over three weeks. During that time, our dive platoon's mission was force protection. Basically, while the British and the Australians were clearing Umm Qasr, we were making sure there was nothing in the water. We made sure that they slept well at night. That was our job.

INTERVIEWER: Why was that? Doctrinally, you guys were there to dive for mines or dive on mine-like contacts. How did you end up doing force protection?

EM1 BEIL: Well, sir, the way it worked out as a dive platoon, we had, I believe, 17 individuals. The group consisted of five SEALs, nine reconnaissance Marines and three EOD techies. So, with our particular background, coming from reconnaissance teams, we were, by far and away, the most qualified to provide force protection.

INTERVIEWER: But doctrinally, you wouldn't be providing force protection. You are expected to have force protection provided for you, right?

EM1 BEIL: Yes, sir. In a perfect world, it would have been a dive platoon clearing Umm Qasr, the whole port. But it was what it was. With war, things come up.

INTERVIEWER: With your background, you guys had the flexibility to do that?

EM1 BEIL: That's correct.

INTERVIEWER: What did you do, in particular?

EM1 BEIL: Well, I was one of two pig gunners on the M-60. Along with that, we established our perimeter, which was the port itself. It was fairly large but I believe we had five main posts and from that, we worked in two-man teams, just keeping watch, making sure that nobody was getting in. There was a great deal of looting going on throughout Umm Qasr. Naturally, with electricity, food or water as scarce as it was, people were scavenging for anything they could get.

INTERVIEWER: Most of them that were trying to break through your perimeter were looters, you think?

EM1 BEIL: Oh, yes, absolutely. If there had been any weapons, there wouldn't have been any more looters. We'd have taken care of that rather simply. But, yes, as soon as they came around, we just gave them a shout and instantly their arms went into the air. They knew the deal. It was 24/7 for just over three weeks. We did that. It wasn't bad at all. It could have been a lot worse.

INTERVIEWER: What kind of a rotation did you guys get?

EM1 BEIL: Well, it actually varied. For the most part, at first, it was just the Guy Platoon.

INTERVIEWER: That was not a whole lot of guys to spread out for security purposes.

EM1 BEIL: No. I spent the first four days at one post. It was just my buddy and me.

INTERVIEWER: You had to take turns taking naps?

EM1 BEIL: Oh, yes. You had to have 24-hour coverage.

INTERVIEWER: How did you get re-supplied with food and things like that?

EM1 BEIL: Well, Gunny Doss was, naturally, in a supervisory role. He and the leading petty officer at the time, Michael Groman, set up the rotation so that they would come around to the posts and re-supply us with food and water, as needed.

INTERVIEWER: How long were you actually in Umm Qasr, then?

EM1 BEIL: I want to say it was about three and a half weeks.

INTERVIEWER: Then, you went back to the USS *Gunston Hall*? Was that the ship you were on?

EM1 BEIL: That's correct.

INTERVIEWER: Was that it, when you guys went back to the *Gunston Hall*, or did you go on to the the other port?

EM1 BEIL: No. Actually, the Guy Platoon didn't go on. We were called back to the *Gunston Hall* and we went.

INTERVIEWER: Did you get to dive at all when you were there?

EM1 BEIL: Personally, no. Some of the guys in the platoon did dive. It was the real world, so you treat it as such. You just never know. You never know. But it ended up that the guys didn't find anything. That was good, too.

INTERVIEWER: You were there to verify the state. Were it unclear, then you would have cleared it.

EM1 BEIL: Yes, absolutely.

INTERVIEWER: Can you tell me about your interaction with the British and Australians? Did you have any interaction with those guys?

EM1 BEIL: Personally, it was quite limited.

INTERVIEWER: Was that because you were on security posts?

EM1 BEIL: That's right, but we had a British ship pull in. They were nice enough to accommodate us a few meals. That was definitely a nice change from the old meal-ready-to-eat. That was quite nice of them. Yes, the British and the Australians, I believe they provided a barbeque or two, if I remember correctly. That was nice.

Conditions were actually better than I thought they were going to be. I was expecting to go in and find everything just bombed out and destroyed. But the warehouses were nice. They were intact. The weather was not bad. The conditions were really good. The guys in the platoon, the guys who actually did get into the water, they pretty much could go slick. Any gear that you can cut down on will naturally reduce any magnetic signature that you can give off. Naturally, your gear is already low mewed, but the less you have to wear, the better off you are. I'm not sure how the viz was. I wasn't down there. They said that it was okay. The water was nice and warm.

INTERVIEWER: What's your background, as a SEAL?

EM1 BEIL: Let's see. I started out with the Charlie Platoon, Team One. I arrived there in 2000.

INTERVIEWER: Were you fresh out of BUDS?

EM1 BEIL: Oh yes, I was fresh out of BUDS. I hopped into the Charlie Platoon. I did the whole workup and at the last minute, I got picked up for the desert patrol vehicle platoon and deployed to the Middle East, Afghanistan, and did some time over there. I finished up with the deployment, came back to the world and decided that I was going to move on. I came over to NSC Team One and in four months I was in Iraq. But I have absolutely no complaints. It's been really good.

INTERVIEWER: You've done a year here and you will stay here for another year or so?

EM1 BEIL: That depends. My clock is ticking away. My clock is ticking down and it depends on whether or I get a school that I've been requesting. I keep getting a handshake and a promise. These guys are pretty good about it.

I'm confident that I'll get my free fall, plus I really do like the command. There are some great guys with whom I'm working. When I first arrived here, I was a little skeptical about that. I thought reconnaissance Marines were all going to be 'belt babies,' just robots. But these guys are very professional. They've got their acts together. They are great to work with.

INTERVIEWER: Do you think working in a hybrid unit like this is a good thing?

EM1 BEIL: Oh, my viewpoint on it is that I think everybody should do it at least once. You learn a lot. I had no idea what a reconnaissance Marine was. Now, I'm impressed.

INTERVIEWER: Is there anything that we didn't talk about that I should have asked about? Is there anything else that you want to discuss?

EM1 BEIL: I'm trying to think of points on the Viper itself. Like I said, aside from the flow rate, I don't see anything wrong with the rig. No, nothing really comes to mind.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF CHRISTIAN J. LAMBERTSEN

Kensington, Maryland

April 2003

## PROCEEDINGS

INTERVIEWER: We're going to start way back. Where were you born, DR. LAMBERTSEN?

DR. LAMBERTSEN: That would be May 15, 1917. Did you mean when?

INTERVIEWER: Where were you born?

DR. LAMBERTSEN: In a small New Jersey town called Westfield. It is up in the northern part of New Jersey. Very shortly after that, we moved to a town called Scotch Plains in New Jersey, which is a tiny town of about 3,000 people.

INTERVIEWER: What about your schooling? What do you remember about that?

DR. LAMBERTSEN: Well, I certainly remember that. As I began, because it was a small town, the schools were small. However, the elementary school at that point in time was very new and looked large. The principal in the school was once the teacher of my father. It's that kind of a relationship that I remember. I know there was no high school in the territory. I remember when it was built and the big impact that had on the community.

INTERVIEWER: Were there teachers that you really remember as having influenced you?

DR. LAMBERTSEN: I know that there were two important ones, in high school, especially. I'm not going to be remembering back who might have influenced me in elementary school. I wouldn't remember their names now. In high school, there was an English teacher who was very imaginative and a big help in stimulating my constructive writing, I also remember well a mathematics teacher who was extremely fine. All of them were positive characters who took an interest in the students.

INTERVIEWER: From there, did you go on to college?

DR. LAMBERTSEN: I did. It may help, and I think it might be of some interest, that this was now the middle of the Great Depression. The high school class had about a hundred students and I think I was the only one, out of the whole class, who then was able to go on to college after

graduating. I think that is important because things in those days were so absolutely out of control, financially, for everyone, as you can probably imagine. I now remember, as you ask the question, that I didn't go right on to college.

I went to an institution that was established to help situations of my sort, a nighttime junior college. I went for two years there. It was about twenty miles away. I had a job during the day and went to the junior college at night. I was their top student at the end of two years of junior college.

The faculty at the junior college was made up of moonlighters from Rutgers, Princeton and Columbia Universities who were teaching at night at the junior college and in their own schools during the day to try to help the situation that existed at that time. The situation, in which people were unable to manage to get into college, is what I mean. At the end of two years, as their top student, the teachers took me under their wings and went up to Rutgers with me and insisted that I be admitted in spite of my not having been part of their system. I was admitted into the first year of Rutgers after two years of junior college and graduated at the end of my sophomore year.

INTERVIEWER: Were you focusing your interest at this point toward medicine or medical research?

DR. LAMBERTSEN: At the time, I was about as ignorant as you can imagine. In a small town, there was no great awareness of what medicine was, other than what the local practitioners practiced. There was no concept of research, either. In my mind, purely the thought of going down the medical pathway had been ingrained early and it never occurred to me to do anything but proceed.

In the course of the college work, whether it was the junior college or not, it was clear that there was great general interest in the sciences. At Rutgers, in my two years there, I worked

in laboratories of different disciplines, like genetics. We had genetics in those days, too, as you know. I also worked in botany laboratories and in biology generally, so I had a lot of laboratory experience in just two years. Rutgers really stimulated that interest and I applied to medical school afterward, but only to one school. It didn't occur to me that one ought to apply to more than one school and no one bothered to tell me that. By the way, I was, indeed, commuting during the time and didn't get the chance to live on the college campus. That was part of life in those days. You did whatever you had to do. I worked as a carpenter, helping to build houses during the day. I think that led to my ability to use time well, because study time was not very plentiful.

I still came out very high, scholastically, at Rutgers, as I had in junior college. I applied to the University of Pennsylvania (Penn) and went for an interview. When you interviewed at a medical school, your goal was to get the interviewer to treat you well in the selection process thereafter so that you would be chosen. I didn't know even that. I was so unaware, coming from a small town.

When I finished the interview, I simply asked the dean whether I would be accepted and he said yes. That was the beginning of a very fine situation because the medical school at Penn was a great experience right from the beginning. Again, no one had any great financial capabilities. Tuitions were low, but they existed. This was the period of time from approximately 1939 through the next four years, or the tail end of depression. A very fine situation occurred in the country. The Progress Administration evolved and there were dozens of tiny jobs at 25 cents an hour, of which I had a half dozen. Those jobs helped me get through the first part of medical school. I then got the one scholarship that existed at the medical school and then the whole situation was under control.

INTERVIEWER: Were you beginning to focus your interests in research, in the breathing

apparatus?

DR. LAMBERTSEN: I did, yes. This story may not have much relevance, but in the course of remembering where we were, you stimulated it. There wasn't much time in those days. There was a lot of action, and yet, it felt loose and easy because everybody was so constructive in the course of backing up whatever was going on. The interest in what you call 'research' came out of the fact that the courses that we had were, in themselves, so stimulating. The teachers in those days were focused on teaching and dealing with the students, as opposed to chasing after graduates, and there weren't any graduates to go after at that point, that close identification occurred between teachers and some students. I was one of those who had a lot of close identification with different teachers.

INTERVIEWER: Were some of those professors that you really enjoyed?

DR. LAMBERTSEN: Yes. There were quite a few, but in particular, an Englishman who was probably near retirement age but incredibly dedicated. For instance, when we had a laboratory situation in the medical school, in physiology, he joined in those experiments. He was right there, helping to design experiments with the students. As a result, it wasn't just a routine experience. We invented things to accomplish.

INTERVIEWER: Was he Cockburt Bazet?

DR. LAMBERTSEN: Yes, he was. He was Henry Cockburt Bazet. I think that out of that was where the pattern of thought of a heavy outdoor life really began for me. I did enjoy swimming and did develop a heavy breath holding capability, which was extreme when I was in an athletic situation. This was not formal, but this was in the course of doing things in the medical school.

That meant that coming into the physiology laboratory there was suddenly an interest in learning about breathing and respiration. That opened up ways to make things happen in the student laboratory that hadn't happened before. It wasn't research. It was just doing experiments.

One of those experiments was to breathe oxygen and hyperventilate to reduce the carbon dioxide pressure in the body. This was a conceptual thing that, when done severely, allowed me to hold my breath for ten minutes. That was a big step in our laboratory, the student laboratory, and that's because it took a lot of time for the carbon dioxide to build up again. The oxygen was there. Now, there came a point at which that teacher and I began to have even more stimulating interactions and I had priority access to any materials, parts, equipment and so forth in the teaching laboratory, after hours. That was what the relationship was like. Other relationships I had were good, as well. I think the relationship with Bazet was one that was such a focus. It went on for the full four years afterward.

INTERVIEWER: Were you then beginning to focus on this research that Bazet was encouraging you to do on a breathing apparatus?

DR. LAMBERTSEN: Yes. That is exactly right. It was on human breathing and why people breathe like they do. There are reasons and they were largely unknowns at the time. The physiology of the human system made it obvious that there should be ways to capture an atmosphere and re-breathe that atmosphere.

INTERVIEWER: You mentioned earlier that you have had many professions, one of which was a carpenter. Were you good with your hands? Did you have access to the necessary parts and materials?

DR. LAMBERTSEN: I was good with my hands. I was mechanically oriented and conceptually mechanically oriented. The material to which I had access was laboratory junk. Nobody bought new equipment in those days and there were old, used breathing bags and old odds and ends of tubing and whatever. Doctor Bazet, however, was so imaginative that when I began to do something, he could see that I needed more equipment. Therefore, he thought he would write to the head of an anesthesia company and communicate that he would like to have one of his

students get some parts so that the student could go on with a development that had been started. That led to the next step.

INTERVIEWER: Was there any direction toward developing something of a practical nature?

He was an Englishman, and with the tenuous situation in Europe at the time, was the idea in his mind, or in yours?

DR. LAMBERTSEN: Yes, it was. That came up very early because Doctor Bazet was not only a great citizen of the United States at that time, but his connections were strong. His awareness of what was happening in England was strong. Can you picture France in 1940? France was finished and the Battle of Dunkirk had just happened. Since that was the situation and Europe was really overrun, across the board, and the regions around the Mediterranean were also being overrun, Bazet knew, as I did, that Britain was really in a severe difficulty.

I don't know whether he influenced me or not. I don't think he did, but radio did. Radio was our source for what was going on every day, here and across the ocean. I'm sure that as I began to put the system together, I didn't think that it might have a military application.

That was the beginning. I built and tested it at my base of operations, a summer job with the Ohio Chemical and Manufacturing Company. That was the same company that Bazet had written to for parts. The president wrote back and said to send me out. He said that they would give me a job for the summer. That was where I put a system together. Once it worked, it was obvious that it should have military application.

INTERVIEWER: Was it the re-breathing mask on which you were working?

DR. LAMBERTSEN: It was a re-breathing system that provided pure oxygen and removed the carbon dioxide in a small canister, allowing you to do rather severe exercise for about half an hour underwater and swim neutrally buoyant. That means you weren't a diver walking on the bottom but a free-swimming diver, and it worked like a charm just from the very beginning.

INTERVIEWER: Could you describe what that unit looked like?

DR. LAMBERTSEN: It was pretty flimsy. I had to make it happen in such a short time because it took only a few weeks to construct a good, working system that summer and trying to improve upon it. Imagine two breathing bags, one behind each shoulder, connected by tubing used in anesthesia machines. That tubing led to a container that had sodalime in it and an alkali material that removed carbon dioxide, and a single tube from that canister up to a mask. The mask was one of the first aviation masks ever built. Coming from the pipe stem to the mask was a step in aviation.

They used to simply stick a wooden pipe stem in the mouth and take oxygen while flying at high altitudes. No full-face mask was used, just one that covered just nose and mouth. Goggles were made with a welding system that allowed you to seal the goggles against the water outside, and a bit of lead to counter-balance it so that it was neutrally blended. There were no swim fins.

INTERVIEWER: Were you influenced by any of the diving literature by other researchers who were doing work like this?

DR. LAMBERTSEN: I'm sure I was heavily influenced by, first of all, the USS *Squalus* event and the fact that there was a submarine escape apparatus that seemed sensible. It was, as you probably know, something that was useable to come up from the depths, but not to go down into them. It was not a diving system, but an escape unit.

I was stimulated by some of the more popular books. I don't even recall the name of the author now, but there was one book, *Danger Is My Business*. It was obviously the sort of thing I read with great interest in diving.

I think it was obvious that it was a different situation. It wasn't the big hard hat diving with the big suits and the 200 pounds of weight and walking with hoses to the surface. You were a free agent and that was very different.

INTERVIEWER: Was it the prototype that you had made?

DR. LAMBERTSEN: It was originally intended to be a life saving apparatus to be put on, quickly, by lifeguards if someone went down in the water. It was to be able to be put it on within approximately two minutes. A lifeguard would get in the water and be able to stay there to recover that person. That was its initial purpose. Once it worked well, and with the unfolding events in the world, the concept evolved toward having a military use.

INTERVIEWER: Were you still working, as you said, with a shoestring budget?

DR. LAMBERTSEN: Still, I had other jobs, yes.

INTERVIEWER: Did the Ohio Chemical and Manufacturing Company provide you with the materials?

DR. LAMBERTSEN: They gave me a summer job. I don't even recall whether there was any reimbursement, but that job allowed me to do what I wanted to do with their materials.

INTERVIEWER: Did you graduate from medical school in 1940?

DR. LAMBERTSEN: I graduated in the early spring of 1943.

INTERVIEWER: There was a military obligation on everyone at that point. What did you do?

DR. LAMBERTSEN: Well, mine was easy, because I made a commitment while I was a freshman in medical school and saw what was going on. I just signed up with the reserves at that point.

INTERVIEWER: Was that in the Navy?

DR. LAMBERTSEN: No, it was not. I'll tell a story that you will enjoy. I tried to join the Army Reserves. In the Navy Reserves, you had to go through a medical exam. They asked a simple question: "Do you have any medical problems?" I mentioned hay fever, and that disqualified me from joining the Navy. It was not sensible, but the medical examiner at that point was not very aware. I just switched over and joined the Army.

INTERVIEWER: Did you become an Army medical officer in the Reserves?

DR. LAMBERTSEN: Eventually, I became an army medical officer, yes.

INTERVIEWER: What was that experience like? What was your obligation there?

DR. LAMBERTSEN: After the first year of medical school, I was connected with the Office of Strategic Services (OSS), which was evolving. In 1940, I built and tested an apparatus, and then demonstrated it to the Navy. After having demonstrated it to the Navy, they concluded that there was no sensible application for it in the Navy's system. It was 1941 and Pearl Harbor hadn't happened yet. We weren't yet at war and we weren't really doing a lot to help on the other side because there was a bit of resistance in the country to getting involved in the conflict.

The OSS had its seed planted by General Donovan's mission to Britain to learn how likely it was that Britain would be able to sustain itself against imminent invasion. Paris was gone and the British forces were driven out of Europe, so there was an extreme situation in the world. On that basis, I made another visit to the Navy, at which time the fledgling OSS personnel, the few that existed, caught on quickly and decided that we would join forces. I became an unofficial component of the OSS as a sophomore in medical school.

INTERVIEWER: Were they particularly interested in your breathing apparatus?

DR. LAMBERTSEN: They were interested in the concept of having men to be able to do what they felt was needed, namely unconventional warfare, and that included sabotage.

INTERVIEWER: Did you ever meet with General Donovan?

DR. LAMBERTSEN: I did, yes, but it was a very simple kind of meeting. He didn't come to demonstrations. He was much too occupied for that. I don't recall much about it. It would have been in an office. The commitment that the OSS be formed was not really acted upon until 1941, until the months before Pearl Harbor. The OSS was officially formed by then, though, and that meant that once Pearl Harbor happened, the U.S. was in the war, and my role began to

accelerate. It accelerated in terms of training people, because the OSS had recruited individuals into teams of swimmers and trained them as individuals capable of handling almost anything in the water.

INTERVIEWER: Were they trained as operatives?

DR. LAMBERTSEN: Yes. They were trained as operatives, in all but the final training section on underwater activity, and I conducted that. I carried that out as a civilian, initially for the first group, and, since I was a reserve army officer, I was forced to continue medical school, because the medical department would not allow students to do anything but finish medical school. I had to work with the OSS while I was completing medical school.

INTERVIEWER: That was a very odd arrangement, wasn't it?

DR. LAMBERTSEN: It wasn't an arrangement. It was simply what people did. Nothing was arranged. I just did whatever they needed me to do.

INTERVIEWER: Did they call you?

DR. LAMBERTSEN: I went, and my dean wrote a letter to the faculty, directing them that I had his permission to do whatever I felt like doing when I wanted to.

INTERVIEWER: Did you have, being in medical school and then getting out of medical school, an obligation to go for Army training?

DR. LAMBERTSEN: Yes. I had to, but as a medical ROTC student, I went to field training during the course of one summer. That was part of it, and as I left the medical school, I went into the Army and had to go through both field training again and through a period of hospital training. They were a few months at a time. During that time, I continued to work with the OSS.

INTERVIEWER: Where was the training?

DR. LAMBERTSEN: Field training was in Carlisle, Pennsylvania. The hospital training was in Santa Barbara, California. How does one continue to work while going through training? I was

redesigning the apparatus and making an improved one that would stand up under military conditions.

INTERVIEWER: You were affiliated with the OSS at that point. Was it was a really top secret operation?

DR. LAMBERTSEN: It was, indeed.

INTERVIEWER: Did you then go down to the Caribbean with the OSS group, to train?

DR. LAMBERTSEN: My obligations to the medical department of the Army were finished. My orders were already cut to go to the OSS. I reported into Washington, D.C. and immediately went on with an assignment.

I went into the headquarters of the OSS, which had a maritime unit with a unit head. The head of the maritime unit was the former mayor of Providence, Rhode Island, and a Navy lieutenant. He was the head of a large maritime unit by that time.

Men were recruited and had their primary training during that past year. As I reported to that office, I asked the head of the maritime unit what he would like me to do. He replied that I ought to tell them what I wanted to do. We agreed that I should go out to the Ohio Chemical Company for a couple of weeks and put the advanced equipment into production.

INTERVIEWER: Did you have only one prototype unit at this point?

DR. LAMBERTSEN: Yes. That is correct.

INTERVIEWER: How many people needed the equipment?

DR. LAMBERTSEN: There would have been, by this time, some fifty or more, but not hundreds. At that point it was about fifty, but they recruited another group after that. The total number in training was about a hundred and the total number of pieces of equipment built was about 250. My main point is that the first task I had to do was to convert a prototype that I had made by hand. In three weeks it was in production.

INTERVIEWER: Were there any modifications in the production model?

DR. LAMBERTSEN: Oh, yes, of course. They were improved in the quality of their materials and in the construction of the mask. We couldn't make new things. We had to adapt to existing things. There wasn't time to do what is done now. We could not spend ten years designing a mask. I took a sand blaster's mask and rebuilt it in order to give it better vision and mounted valves, allowing you to choose whether to breathe air while the mask was on. It also allowed you to drain water from it if you got water in the mask and to shut it off so that if the mask came off or you took it off, you didn't sink. You could float on your breathing bag. All those things were done within a three-week period with good machinists and people in the anesthesia company. They were not diving equipment manufacturers.

INTERVIEWER: You weren't really concerned with the monetary arrangements? Did the OSS take care of that?

DR. LAMBERTSEN: There were none. It wasn't worth talking about. The monetary arrangements were never even considered. The first purchase of equipment was four units of the pre-final apparatus and couldn't be afforded by the OSS because the OSS had no budget. They split the cost with the British. The British paid for two and the OSS paid for two at something like \$150 each. That's why finances were not something that got in the way.

INTERVIEWER: Did the British have an interest in this because they were having a problem with what was called 'shallow water blackout'?

DR. LAMBERTSEN: Yes. The British had gotten from me, and then from the OSS, the message that there was something that they would be interested in. My professor helped with that back in 1940. In the fall of 1940, he wrote a letter to the person I think was called the 'Director of Scientific Research and Experiment,' and the admiralty. That letter announced our message to the British and they were hungry for everything because they had needs of the same nature.

They sent a couple of British medical officers to here by boat to talk about shallow water blackout. They were losing men with their primitive diving systems. The reason was inadequate training, not the equipment proper. The problem was with the lack of oxygen when they did not remove the nitrogen from the breathing system as a routine task.

INTERVIEWER: Did they have an interest all along? Is that why they partnered with you?

DR. LAMBERTSEN: We had close communication all along, yes. In the beginning of 1944 we had promptly sent a team of swimmers using the primitive equipment at an OSS maritime station in England. That was before the final model was sent over to England, and they had only a total of four units to prepare for missions on submarines, which they never got to do.

INTERVIEWER: General Donovan, as I understand, was developing a doctrine for the OSS and this maritime unit was going to be the way that doctrine was carried out. What was that doctrine, as you remember it?

DR. LAMBERTSEN: I do know that the knowledge that led to the doctrine was that the need existed to help surgeons in the resistance in occupied countries. That force was not going to be able to do it under the circumstances of near total completion of a conquest. Entering by air was a one way street but entering by sea was a two-way situation. His doctrine, and the reason for ultimately establishing a maritime unit, was that he wanted full use of that sea entry for delivering agents, for recovering agents and for sabotage.

INTERVIEWER: Did you provide him with the tool he needed?

DR. LAMBERTSEN: It was such a strong part of the maritime concept that it became almost a focal point for building other kinds of concepts around it. That was why when it became sensible to think in terms of longer-range activity that a swimmer could do on his own there was a rapid acceptance of the concept of incorporating Britain's submersible canoe that it had developed. The swimmers with whom I had developed the tool and brought together under the maritime unit

allowed us to have a swimmer delivery capability, by which individuals could go for long distances, become swimmers and then come back as swimmers and come back the long distance. We expanded the concept in flight. It all happened in months.

INTERVIEWER: Was Dennis Roberts the head of the maritime unit?

DR. LAMBERTSEN: Yes.

INTERVIEWER: What do you remember about your relationship with him?

DR. LAMBERTSEN: I remember him very well. He was good, honest, and a tremendously positive person. My knowledge of where he came from came later. I didn't know that he was a great water man. He was a great sailor and boat man. He knew the sea, and he knew a lot about it.

He was a Navy lieutenant in charge of a worldwide operation and it always surprised the Navy that he had Navy commanders around the world and was their boss. They didn't like the thought of that. The current Navy doesn't understand how that can work. As I remember him as a person, he was the one with whom I spoke when I finally came in, a brand new army officer reporting for my functioning assignment. His statement was that we think you ought to tell us what to do.

INTERVIEWER: You were an Army lieutenant at that point, weren't you?

DR. LAMBERTSEN: I was an Army first lieutenant, yes.

INTERVIEWER: Did you have, as an Army lieutenant, a considerable amount of influence over what was happening there?

DR. LAMBERTSEN: From that point on, I had absolute influence over what happened with what we called 'operational swimmer activity training.' As we went to the point at which the equipment was committed, I came back from Ohio Chemical after those few weeks and went down to the Caribbean. On the way down, I very rapidly wrote a manual so that I'd leave

something behind if I disappeared. Having gotten down there, we already had the first big OSS group in training with the prior equipment, which was not, in my judgement, suitable for military operations.

INTERVIEWER: What was that equipment?

DR. LAMBERTSEN: It was my second model, the one that I hardened from the life saving system into what the OSS could see was useable for several hours in the water. It didn't have resistance against corrosion. It didn't have all the life saving features or floatation features that you would have in case of emergencies. It was the first functioning true underwater closed circuit breathing apparatus. That was what it had as its mark, as opposed to breathing in and out of bags. It was a system that let you breathe out through the canister, leaving the CO<sub>2</sub> to be absorbed, breathe the next one out, and have that absorbed. The men who were there were all Navy men, and as I came in, they went out, and they had gotten their training only through a preliminary start of training a couple of their people and, subsequently having them become trainers. That was just breathing system training.

They had already had the ranger training and all of the small boat training, and therefore, were assigned to the Navy. The Navy requested them and assigned them to their new underwater demolition teams. They were assigned to team ten and became the nucleus for that.

When I went down, it was after the first group had gone through less than what I considered thorough training, but there was no choice. I had to make the new system come into being.

INTERVIEWER: What time period was that?

DR. LAMBERTSEN: It would be about the spring of 1944. They were leaving and I was going down there to pick up the training. I had a limited influence on that first group.

INTERVIEWER: Did the first group go out with the Navy?

DR. LAMBERTSEN: They went with the Navy.

INTERVIEWER: Were things developing in the Pacific war, as far as the amphibious operations in the islands? Was that why they needed these people?

DR. LAMBERTSEN: They were doing a great job, all of them. The Navy was doing that. But it began at the same time. In 1943, we were beginning in the OSS, so we started together. Our OSS people went to the heads of the Navy system in Fort Pierce. The head of that was Draper Kaufmann, who was a very famous Navy person and once head of the system here. It was obvious to our OSS people that there was no way that they would be able to be saddled with having to learn how to breathe under water at the same time, because they were going to have to use massive numbers of people and work in daylight.

INTERVIEWER: Was the OSS training you spoke of in the Caribbean out of Fort Pierce?

DR. LAMBERTSEN: Yes. The Navy training was at Fort Pierce. The OSS training was on a very small island about three miles long and one half mile wide, off of Nassau. It was under British jurisdiction then, but the British were not even allowed to fly over the islands. In other words, the British military was not even allowed to fly over the island because of the security of the training. We simply took over that island and used it as a training base, while we lived on the shore and came to the island each morning, back and forth. We had no special facilities.

The nature of the training was that the second group was now under a different training system, and I was named as the trainer. I was the medical officer and the trainer, and it was obvious that I had to become the demolition trainer, as well, because we had no adequate demolitions. We had to design and build the kinds of things we needed to use. We were working in water with systems that would behave and go off when they were supposed to go off, and not just blow things up. As a result, we had to design and build some of the kinds of equipment with time delays that would not be ruined by an accident of moisture. I think the important thing was that the second group of OSS people had the chance to train on the final apparatus, and that

meant their skills were very far above those of the previous groups.

INTERVIEWER: They not only had to be trained as swimmers but also had to be trained to use your mask?

DR. LAMBERTSEN: Yes. That was not hard to do because they were all water oriented and volunteered for something that had to do with water. That was all they did. They didn't know what it was going to be. The training was very specific in terms of how you learned to avoid getting killed in the process. Therefore, they started off with great confidence and had no difficulties.

INTERVIEWER: Were you then involved not only with the mask you were making? You were a demolitions expert also?

DR. LAMBERTSEN: I had to be. I had to do that because it was imagination that was needed. I had to ask myself, "How do you put these things together? How do you make all of this fall into place?" To work at night and to learn how to go from one place to another and not be seen meant we had to devise the navigation system, something that would attach to the breathing system so as to be there, visible, as you were swimming.

They now use an equivalent but hold it in their hands instead. They call it an 'operations board.' Are you familiar with the attack board? The Navy SEALs now use the equivalent, and they use it as a hand held device. We snapped it up in front so that it would come under our faceplates as we were swimming and could hold a course and find the course back. We made things in place in the field to expand the operational capability. We ended up being able to talk to each other underwater, and that was lost instantly after the war. It was thrown away.

INTERVIEWER: How was that done?

DR. LAMBERTSEN: I got earphones from the British air station and took them apart and made them into mouthpieces to mount in the mask. The diaphragm of that earphone became a

transmitter that took the sound waves of voices into the water. Then, the ears themselves were the receivers, and for something to the order of 75 feet or more, we could talk to each other. That was lost right after the war and never came back.

INTERVIEWER: Was that stage of the operation pretty much the way you had been working your whole life to that point? Was there no procurement officer? Was there no way? When you needed something, you found a way to get it?

DR. LAMBERTSEN: That was the first stage. But then, the OSS was evolving. One of the things that evolved was what I remember was called a 'research division,' and it was there to devise things that were needed. When I devised the speaking system and sent the details of it to the OSS, not knowing even that they had it because we were not talking to each other, we were off doing training, and they then immediately provided enough good ones to go around.

INTERVIEWER: What was the island called? Was it Treasure Island?

DR. LAMBERTSEN: Yes. That's right.

INTERVIEWER: What was the administration set-up of this maritime unit, while you were there? Was there an administration set-up?

DR. LAMBERTSEN: You're a very wise man. We had someone who was at a base, even though the base was nothing but a house. Whatever was needed, he got. He was a reserve naval lieutenant commander and had no connection to, or functions with, the training. The next person was called the 'training officer' and was a Marine captain who had been hurt badly in Guadalcanal. He was named Sullivan and was appointed the training officer, but he was not the training officer. He was just named that. He was really the authority over some young characters that were these brand new, young guys from the Coast Guard, the Navy, the Marines, and the Army. They were the swimmers. He was what you would call the 'head of troops,' but there were only about thirty troops.

INTERVIEWER: Did he have any natural ability to do this?

DR. LAMBERTSEN: He had none.

INTERVIEWER: He didn't?

DR. LAMBERTSEN: No. He was a Marine. He had a natural ability but he didn't need it for that. He needed to be that figure and he was. He never took his shoes off, never got them wet, and he never went near the water, but was respected by the guys. Administratively, but organizationally more than administratively, the total of about thirty people was divided into three platoons, such as they may have in the SEALs at this point.

The platoons were not divided in accordance with whether they were Army, Navy, or Coast Guard, but they were Army, Navy, and Coast Guard all together in the same group. Whereas the previous group one was all Navy, that one was a mix. Each of them had a lieutenant junior grade as a head. One had a Marine second lieutenant, one a Coast Guardsman lieutenant junior grade and one was an Army head.

Men of different backgrounds headed the three platoons within this group, but it didn't matter. They were all there because of what they were doing. It had no relevance as to whether they were from the Coast Guard or whatever. They all had heavy water experience beforehand. My roles were multiple and without anybody saying what they were. I was there to make something of the system. I was also medical, so I was also there to take care of any medical problems.

INTERVIEWER: You had no boss?

DR. LAMBERTSEN: I had no boss, no. When the head of the base began to intrude on the training and interfere with what I thought needed doing, all it took was a telephone call and he got the word from headquarters to get out of the way. That was the way it was. I never thought of it that way. There was no officiousness on my part. I was brand new. I was just doing it, and it

worked.

INTERVIEWER: That would never work today.

DR. LAMBERTSEN: No. It wouldn't work today. It would not work at all.

INTERVIEWER: It was a very unique time.

DR. LAMBERTSEN: I think that you get the feeling that this was loose, but purposeful and dedicated, on the part of everybody. Security was so high that I didn't even know what was going on the other side of the world. I didn't even know what the Italians had been doing. I didn't even know that, in spite of the fact that we were generating an equivalent.

The men with whom I worked were very much security conscious and I was very security conscious. We had a big storm once and it washed the whole bloody bunch of us away from land. We were scattered out there but wearing the underwater breathing apparatus, and those people had trained with it and had the equipment that could float them, but only if they used it so that it would float them. One of them got scared and took his equipment off because he knew he could handle himself in the water. He was just plain scared, and it meant that he decided to ditch his equipment, whereas the others did what they had been trained to do, namely turn the valve off and float on your breathing bag. It became a life jacket. I raised so much grief with those characters at the end of that that they all went out and found that equipment.

INTERVIEWER: Was it expensive equipment?

DR. LAMBERTSEN: Well, it wasn't the cost. It was that I didn't want it to be picked up by somebody.

INTERVIEWER: Oh, is that right? The security was that tight?

DR. LAMBERTSEN: Yes, and I gave that guy so much grief that he thought I was the worst guy in the world. He told me he should have drowned himself. You know how it was there. It was a hard wartime situation that caught up everybody. There was no administrative interference from

the OSS. There was absolute commitment from them. However, the real question was when would a group of that sort really be ready? One had been sent out and absorbed in such a way that it was obvious it probably wasn't going to be used, even though the equipment was sent off. The best equipment was sent right off after it. They took the equipment they used for training and had delivered it to Pearl Harbor. This was the advanced equipment that I had finished getting produced.

INTERVIEWER: Was that the Underwater Demolition Team (UDT) group that you're talking about?

DR. LAMBERTSEN: With the one that went into the UDT, we assumed everything was going to be fine, but it was not. They did a great job in bringing swimming into UDTs, and I mean real swimming, because the UDTs did not have much swimming training or guaranteed swimming capability. They were just generating people so fast.

We had some of the world's best swimmers in that first group, Olympics-type swimmers, candidate swimmers. One was called the 'fastest swimmer in the world.' They were the kind of people that we had. They were in the teams out there, such that the head of the Pacific fleet wrote to Donovan to thank him for having given him a chance to have people upgrade the swimming in the UDTs, and that was a great thing. They brought fins into the UDT system, the swimfin, which they hadn't had.

How do you work when there seems to be nobody in charge? One of the things that had to be decided was when those groups would be ready to go. Roberts came down with the headquarters staff of the maritime unit to appraise the situation, more or less. It was not an officious bunch coming down. They were coming down with full confidence that things were okay. I did the obvious thing. I set up a nighttime operation for them and let them be the targets.

INTERVIEWER: Was this that famous incident?

DR. LAMBERTSEN: Yes. You know just what I'm driving at, don't you?

INTERVIEWER: Yes, I do.

DR. LAMBERTSEN: Everybody agreed that there would be a live attack, because there was no point in doing something if it was not real. At that point, it was not a peacetime situation and the need was to get as many people involved as possible, even though ultimately one person may have done a task.

The eighty-foot boat, the only boat we had, with everybody on it as observers, team members and the people visiting from Washington, became the target. The rubber boats were called LCRs then, or landing craft rubber, and paddled by inflatable boats. We paddled about 300 or 400 yards from the boat.

I chose the youngest swimmer in the team to join me as a partner in making this run on the boat. I was going to do it because I surely didn't want it to fail. We stuck together on the way from the rubber boat and hit right on the anchor line of the boat. Our targeting was using compass and having, not anchor line, but the heavy chain anchor. We hit the anchor chain, and I had communications so that I could talk to my partner. I told him to just stay put while I took one half pound of TNT. It wasn't big, but it was big enough, and it had time. What we called 'time pencils' were delay detonators set at a half an hour. The boat had a big, five-gallon bucket over the side with a rope, and everybody was looking for action. They saw nothing of what we did, and time passed, so they assumed it had failed and begun to pay little attention until someone pulled up the bucket and found the charge in it. That meant that my partner was sitting on the anchor and waiting for me to come back. It was all moving quickly at that point in time.

I had to get out of the way of the anchor. There we were, and the anchor came up, the bucket came down, and the boat took off like a shot. There were two people under the water in the dark with the rubber boat out there somewhere, not in connection with each other. Darn it if a

fine young fellow didn't just keep calling through the water, "Oh Doctor, where are you?" over and over and over again, and I honed in on it. I honed in on his voice, and we swam back, and that was the end of that. Roberts decided we were okay.

INTERVIEWER: You were ready?

DR. LAMBERTSEN: We were ready. That was readiness. It was a live charge that went off. We swam far enough away to get out of the way of the blast. That solved the problem of readiness, so we were immediately able to wrap up and proceed.

INTERVIEWER: Where did you go from there? Where did the team go?

DR. LAMBERTSEN: We went back, quickly back. We broke up into two teams. I know that our primary task was to go to Guantanamo Bay to very carefully arrange things between the head of the OSS and the Navy to use our trained swimmers to help judge the security of the bay's defenses. It was a well-planned Navy operation in which we joined the Navy and that meant joining them at Guantanamo.

But the techniques of what was done were techniques that we decided upon together. I was delayed only a bit in getting there because I had gotten a hand infection, and we got some of the first penicillin that had been made to cure that infection, so I joined them at the beginning of the Guantanamo operation. Are you interested in knowing what the nature of the operation was?

INTERVIEWER: Yes. That was going to be my next question.

DR. LAMBERTSEN: That was when I thought that it would be wise to point out two separate things. One was a full-scale attack on the harbor as though it was an operation similar to what we did with the 80-foot boat, and it was done. We had the benefit of a submarine that time, but I don't remember its name.

They approached within about a mile or two of a secondary submarine, offloaded the rubber boats, and the swimmers, in their rubber boats, were able to get over and through the nets

with those boats. They then entered the harbor. It's a big harbor, of course. They had designated targets within it. They were derelict targets, so that they could actually make limpet attacks on the targets, and they did that successfully.

That was kind of an all night mission. There were boats, Navy and otherwise, observing other boats. The second part of it was a multi-day thing that went on probably for almost two weeks during which the swimmers were demonstrating what they could do as individuals to the net defenses themselves, as opposed to planting charges on shipping vessels. It was astounding what could be done because of the way in which we were able to use charges. It usually involved linking charges using primacord, which is an explosive cord that once it's set off by a cap, the explosion instantly travels down that cord, no matter where it is and how it's laid. We were able to drop torpedo nets right out of existence simply by having swimmers put lumps of plastic explosive, like composition C, which was an original plastic explosive, in the shackle like fittings. After having run primacord through them so that the primacord flashed through in a fraction of a second, each explosion went off, the torpedo nets disappeared, and it was a mess getting them up off the bottom thereafter. Nevertheless, that was one example of the kinds of things that they did.

They even went so far as to try to prevent the gauge from opening by rigging systems that linked the two giant gauge systems so that they at least had to not do as they were supposed to do. I don't know whether they could have been broken open or not, but nevertheless, the trials were made. That could be done. Torpedo nets could be raised from the bottom by a sort of block and tackle. They could raise whole sections so that you could take people and get them underneath the nets if you couldn't get through them. I think it was that kind of multiple tasks that then made the ordnance that the senior Navy group was involved with it. I have a good story about their security, which was beautifully documented and put away so tightly that it didn't

come out until about four years ago.

INTERVIEWER: It came out recently?

DR. LAMBERTSEN: Oh, yes. It was a very tight report. I did not see it until it was finally released about four years ago. It was hidden in all of these archives under much security so that it was not released. That's why I never saw the results of it until just a few years ago.

INTERVIEWER: You had a two-fold out of it? This operation also showed the offensive capabilities of this new system?

DR. LAMBERTSEN: Yes, but it was designed to show defensive faults and it didn't.

DR. LAMBERTSEN: That, at the beginning and middle of a war, is not the sort of thing that anybody wants floating around. The Navy did a proper job. They did a beautiful job of managing that effort, backing it up, and the OSS people came in to be actors in the scene. I consider that a Navy operation.

INTERVIEWER: The people were trained. They were using your unit. They were well trained and they were ready. Were they ready to go to war at this point?

DR. LAMBERTSEN: Yes. Yes, they were.

INTERVIEWER: Where did they go?

DR. LAMBERTSEN: You have to realize how ignorant a first lieutenant in the Army was when the world was geared around secrecy. The OSS had to make things happen and let you know what was sensible to let you know, as a first lieutenant, even if I had to make the whole system work. All I knew was that we were going to be going over to what was called the 'southeast Asia command,' and the word was that it was a base in what was not a war zone. It turned out that Donovan had come to an agreement that we could use this group. That was the key element. We were going to join the system. I never knew anything about that.

We split. The men were put in their pathway for being sent over, and I had to stay put for

a couple of weeks anyway, in order to get some more documentation into the system so as to not just walk away and leave things out of control. I'm trying to picture now how they went, and I have a hunch that some may have gone by ship. I don't know how they went, because I was delayed in getting over there due to the fact that I had to ultimately pack up the equivalent of what I would need for almost two years and create medical support. My block was there because I was on another track. I generated containers that were tough containers, field-like containers full of whatever I thought I would need, medically, in a remote region to back up the people where there was no one else to help in any way. I went so far as to pack sterilizing equipment, instruments, things that you would not think of, in terms of ordinary odd medical backup for something, drug supplies, and tropical medical. I had to invent this by myself.

There was no one in the OSS who said, "Well, there's the stuff you ought to take." I had to create not only the equipment requirements for the swimmers, but also the medical support requirement at the same time. That was where the block came. I was then off on my own without any of this business, since it had gone with the swimmers.

I traveled from Washington, had to wait for transport, and that took some weeks. That was the disconnect that I mentioned. I left New York and flew to the Azores and then on my own across Africa and India to get to Calcutta, and then I kept on moving down into Burma.

INTERVIEWER: What was that trip like? That must have been a tremendous trip.

DR. LAMBERTSEN: It was on the very fine aircraft called a C-47, which was a two-engine plane with bucket seats. That was what you did in those days. The air transport command existed. They were the kinds of planes that flew the hump over Burma and China then. I had to realize how it was that I was disconnected, and it was because I had to find my own way to where the system was, and as a medical back-up for the swimmer group, I had to be there, and that was it.

Now, at the final stages, the travel was with troops who were going down the coast on foot and by jeep to get to a point where we then took off for an amphibious landing, which my crews were already loaded up for. I joined those people in their landing, and we ended up as backup in the last part of his campaign.

When that was under control, I left, came back and picked up the training of the swimmers and submersibles into swimmer submersibles or what we called 'swimmer delivery techniques and tactics.'

INTERVIEWER: The British had something called the 'Sleeping Beauty,' as I recall?

DR. LAMBERTSEN: Yes. That's the one I'm talking about.

INTERVIEWER: What was that like?

DR. LAMBERTSEN: The British had an equivalent unit, which was a Sleeping Beauty. It was a one-man submersible that was indeed like a steel canoe. It had buoyancy chambers for and aft so that you could let those chambers be filled with water or with air and float, sink or become neutrally buoyant. There were something like four batteries of the sort that we'd put in an automobile, a motor to drive a propeller, and the planes on the stern would allow you to go up or down with the Sleeping Beauty. As you sat in it, you were a breathing apparatus. The British used that system. They had planned to use it heavily in that whole Southeast Asia region against the Japanese there. They had it all. They didn't have the chance to do it, but they, again, had problems with losing people in training.

That same early process that I had to go through with British officers was showing them how to avoid hypoxia. I had to do it all over again in southeast Asia when the SRS knew that we were finally over there, and together we made contact in the head of that system. I then had a proper liaison with their Sleeping Beauty efforts. They turned over a couple of Sleeping Beauties to us, and I used them to teach our swimmers how to become their pilots.

At the same time, they were already expert swimmers, and for that reason, we had almost immediately swimmer delivery capability. The SRS retained their Sleeping Beauty non-swimmer capability, as they did not have the ability to truly swim outside.

INTERVIEWER: The British had a different concept of the swimmer submersible than we did?

DR. LAMBERTSEN: They had the concept that the submersible and the pilot were a unit resistance factor, of which, of course, I knew nothing. We were considered part of the OSS, and it was something that existed without even my understanding what it was when the first contacts began, because they were just direct contacts with people, a Marine captain or a Navy lieutenant at a swimming pool, for example. That was the OSS, as far as I was then concerned. I then learned that there was an office behind it, meaning some people were there. It was a secretary and a Navy lieutenant who seemed to be in charge, and as a medical student, I got to think they were perfectly fine people. They kept in close touch with me.

Then, as it opened up, I don't believe I saw any real change in the way they acted over the following several years. They kept that personal communication approach and never seemed to be in a hurry. I'm sure they had a lot going on. It got to be touchy only when we were in a remote place in another part of the world. My memory tells me that when I showed up at the Southeast Asia command, having gone through the system and then come back up through, I discovered that people there lived a different, disconnected life.

The medical officer at the OSS headquarters was in a town called Candy and had decided that he was now on the OSS staff. I had to disconnect myself from the clutches of the OSS medical department that was so pleased to finally have another medical officer.

INTERVIEWER: But you had another agenda?

DR. LAMBERTSEN: I was still absolutely inexperienced in terms of what was going on in the background because I was focused on doing what we were making happen, and to extricate took

a little bit of time, but it was done. I just wasn't going to do it.

INTERVIEWER: The British had a different concept of the relationship between swimmer and submersible than we did?

DR. LAMBERTSEN: Yes.

INTERVIEWER: What was that difference?

DR. LAMBERTSEN: The difference was very sharp. I think Britain never developed real underwater swimmers. It developed great divers for going up and down because it had the big explosive ordnance disposal, and therefore, their equipment, if you couldn't swim with it, didn't make any difference because you were going to be going down and walking around on the bottom. When you were in the Sleeping Beauty, their concept was that you were in it until you reached your target, and then, if you had to get out, you got out. You had a lanyard connecting back to the Sleeping Beauty so that you were never really a free agent, whereas the OSS groups began as long-range underwater swimmers who could find their way and do things and come back again and find their way back without that transport. Once we got to use the Sleeping Beauty, we had the advantage of the ability to go without wearing the swimmer out and still have additional reserves of swimmers.

INTERVIEWER: At some point, you introduced this method, this new philosophy, if you will, that you had developed to the Navy. When did that happen?

DR. LAMBERTSEN: That was very definite. The war had ended, and now I think the OSS had ceased. As we won victory over Japan and the atomic bomb was dropped, and I believe, without concern over that date exactly, it was close on to the fall of 1945.

INTERVIEWER: I'm concerned over whether it was on my birthday. I was born on that day.

DR. LAMBERTSEN: When was it? What was the date?

INTERVIEWER: It was August the sixth.

DR. LAMBERTSEN: On September 20th, Truman wrote the letter to Donovan that thanked him for his service and terminated the OSS. Can you almost picture that anyone like me would think that was a very bad thing to do? It was obvious that if you were the President, you were not going to want an OSS laundering around inside the country with the kinds of situations that it had built into itself, and therefore, it was not too surprising to me later on. What was necessary was to somehow keep from losing what we had done, and so contacts were made with the Navy.

You asked about when the Navy picked up the swimmer delivery concept and made it part of its own activities. Put aside the fact that there was Army people in there and the Coast Guard, as well. The whole aim was to salvage the concept by broadcasting it. I got to the office of the maritime unit, a physical office in Washington, and it was tearing itself apart; packing up its papers, throwing them away, burning them and doing whatever. When I came in from a long trip back from the west coast I discovered that at that point the OSS was finished.

I was able to get the Navy lieutenant administrator of that maritime unit office, a John Moran, to simply type and sign a secret clearance to open the underwater apparatus and use it, right then and there, in an office, with nobody else there but Moran and myself. That meant I could go and, for the first time, discuss it and talk to someone about it.

I chose to go to the head of the Army engineers, a Lieutenant General Wheeler, I think his name was, and the Commandant of the Coast Guard, and to the head of a few ships that still had a diving section. By going there, I left equipment with each one and managed to obtain equipment from Washington storehouses. The store was clean. I actually got a sergeant and a truck and went and loaded the equipment onto the truck and went to each of the headquarters and deposited two sets of equipment with each one along with the manuals that I had generated before going over. Moran had all of this material. Then, I had to report for duty as a medical officer because I was no longer part of the OSS. I was an Army medical officer at that point.

There was no OSS, so I reported back into the medical system.

It took almost two years before the Navy picked up on the fact that they had been given the open equipment, unclassified, and to have any of it filtered through to anyone in the Navy, such as the amphibious forces, who might have been interested in it. I didn't know that there was such a point of contact.

INTERVIEWER: This Moran fellow, in the OSS, and you just decided it needed to be declassified?

DR. LAMBERTSEN: We did it.

INTERVIEWER: That was it?

DR. LAMBERTSEN: Yes. There may have been some background instructions he had, general instructions, but it was a really catastrophic circumstance for the OSS to close and we had to save it at the same time, save and close and preserve.

INTERVIEWER: You knew at that moment that if it wasn't saved at that point, all the work would have been right out the window?

DR. LAMBERTSEN: At that point, I think the real key was what I didn't know. The swimmers were all in that month it took to get from the OSS closure to my getting back into the report and finding that there was nothing there because there were transportation problems. Moran also had to be the personnel officer for the OSS.

I knew that the men were gone and that meant there was no system at all, and unless something was done, there would be no equipment even. About all I knew was that there was a storehouse in which we had kept the supplies for the OSS.

INTERVIEWER: You went and delivered the units to the Coast Guard, the Army, and the Navy?

DR. LAMBERTSEN: Yes. I simply got a paper receipt, and I've still got the receipt I got from the Navy. It reads, "Ships written, received two Lambertsen units from Captain Lambertsen,

signed somebody.”

INTERVIEWER: But the Navy didn't pick up on it right away? Which of the other services did you have? Was it the Coast Guard and the Army?

DR. LAMBERTSEN: Yes, it was the Coast Guard and the Army. The situation was different. With the Coast Guard, the Commandant was so fascinated by what happened and delivered them right to his office. He took me home, I had dinner with him, and his son was out, so he said, “I've got a bed for you. We'll just talk some more.” That was quick and immediate, and then instantly I was asked, as an officer, to go to the Coast Guard station and set up a training program for the air/sea rescue system at Mayport in Florida.

With the Army, it took a little more time. It took the better part of a year, and then, a system existed. The Army engineer research and development command got the word from Lieutenant General Wheeler's office, “Let's see what you can do to evaluate this potential for...”

INTERVIEWER: But the Navy was the last one to pick it up?

DR. LAMBERTSEN: The Navy was the last one, and it got the word from the Army. The Army informed the Navy, and that led to the head of the amphibious forces, Atlantic, and a Lieutenant Commander Fane, who was the recent head of two underwater demolition teams (UDT), classical underwater beach reconnaissance teams, and he was quick. Once he got notice that there was something going on, he and the Army talked. The end result of that was that I got an invitation to come down and train the Navy UDTs in underwater swimming.

INTERVIEWER: Had the unit changed significantly since they were used during the war at this point?

DR. LAMBERTSEN: Had I changed?

INTERVIEWER: No, had the unit, had the breathing unit change?

DR. LAMBERTSEN: No, not a bit. They were the same. At that point they were the same

stored, original batch. One batch was made and they were exactly the same one that we used during the war. They lasted for almost 15 years.

INTERVIEWER: At that point you were helping to train the UDTs. You were a civilian at this point, were you not?

DR. LAMBERTSEN: At that stage, yes. I had to stay with the Army medical department for about a year because I was a physician and people were hurt, so medical officers stayed on. I managed to get leave of a month or so to go and train the Coast Guard. That training was very fast moving.

Then, I was discharged from the Army and joined Penn. That would have been 1946. It was only a year from the time the atomic bomb dropped. In the fall of 1946, I joined Penn. Within a month or so, I went down and dealt with the Army, and in 1948, the Navy, and stayed with them for ten or more years.

INTERVIEWER: They used your re-breathing apparatus for a number of years as the UDTs' main unit?

DR. LAMBERTSEN: Yes. That's right.

INTERVIEWER: They gave it up at some point, didn't they?

DR. LAMBERTSEN: What they did was very clear. Two things, I think, happened. Leaders changed and therefore, direct communication changed. I think if you picture that if something was made and went through some several years and then some ten more years of working in the field with the Navy, it wears out. Parts wear out. They never bothered to follow up and keep spare parts and things like that.

As things began to get a little lean and the leadership changed, meaning Commander Fane, who was very keen on the whole thing and moved out and began doing other things on the west coast, there wasn't equipment in being, and no manufacturer in being. By no manufacturer

in being, I mean that the Ohio Chemical Company, which had manufactured, for essentially nothing, almost as a gift, these units for the OSS, did not continue to produce them. They knew that their field was not making diving equipment; it was anesthesia equipment and so it was said that it was only sensible that they not make more of them.

There was no such thing as civilian self-contained diving. There were no self-contained civilian divers. I wasn't pushing it because I knew they would get hurt. I purposefully never pushed closed circuit breathing for civilians, and I still don't. What the Navy began to do was scrounge around to try to find what it could use. The aqualung came along, and it was obviously an attractive thing, but it was not useful. It took several years for the Navy to admit that it wasn't useful.

INTERVIEWER: Why wasn't it useful?

DR. LAMBERTSEN: Well, I'm thinking entirely because of the weight and the ability to use extremely heavy equipment. They were used to picking up something with one hand, slapping it on, jumping off the dock, and taking off and that sort of thing. That kind of thing with any duration at all was only a half an hour or so in the course of an ordinary depth run. If you left the bubbles out of it, you dumped every breath as it expanded in the water.

It was not useful for submerged activity. It was not useful for working in and out of a submarine. You couldn't crawl in and out of a submarine lock escape trunk with it. You could get two people in, with difficulty, instead of four people in with ease and all that. It just didn't adapt to any of the things that the closed circuit oxygen breathing adapted. They began to just reach out and try to find what they could get, and they got some old, Italian equipment that had been good for the torpedo men, meaning the charioteers. It did beautifully for them because they were sitting quietly and steering a torpedo. They didn't do any exercise. They were not working.

Its ability to handle the carbon dioxide absorption was not adequate for underwater

swimming. Its positioning, its buoyancy characteristics, were not geared for it. The Drager was a foreign unit that emerged, but it was designed as a submarine escape apparatus and modified to quickly meet a possible market. It became a commercial kind of thing, but was poor, and as a result, there was no source of equipment. So, they played around with it and ended up, more or less, just using the aqualung for a good number of years and lost a lot of the capability. That's the answer. Oh, I neglected one good part, I think. The Army had taken a different approach, and as we finished an evaluation of all existing equipment, it was obvious that it was sensible to go ahead and try to use new materials that were emerging and reconstruct the capability of building an improved, better self-contained diving apparatus. We did it, and I then found a manufacturer, a helper, not for selling it, but for building it. It was named the Emerson Company. It made polio resuscitation equipment.

INTERVIEWER: They made iron lungs?

DR. LAMBERTSEN: They made clearing lungs and those kinds of apparatus. Someone who knew breathing and knew how to put tubing together became a partner with me. We were intellectual partners because I needed someone who could make what I wanted to make. We made a good, new Army apparatus, and yet, by that time, the Navy had begun to try to establish what it would do, and somehow it would not connect with the Army.

The correspondence that went back and forth was beautiful. It was that of how individual naval officers were trying to crack their own problems with their own Navy to try to get communication going where they knew equipment existed. Finally, we just turned the thing around and I said, "Let's now call this new apparatus the 'Emerson equipment,'" and it solved a lot of the problem of people thinking, "It's just the Lambertsen apparatus again." When we did that, it opened the way to a pathway, a long, long run. It took nearly ten years to go from that immediate reconstruction in the Army to getting the Emerson, what's now called the 'Emerson-

Lambertsen; or the 'Lambertsen-Emerson,' or whatever, but then called the 'Emerson,' into the fleet. That ten years was a very poor time because it was a time when the Seal system hadn't emerged in full and the amphibious forces had not any picture of how they would use the UDTs with swimming equipment.

We had a limbo situation. The UDTs had poor equipment and were struggling to get some equipment that would work. The Emerson became that unit in the Navy. The Army and Navy tried to work together temporarily, but then it wasn't worth it, and so the Army went through extreme evaluations and put it aside as something that was just not going to meet its evolving purposes. That kind of equipment couldn't stand the heavy power-shoot operations and that kind of thing. As a result, the Army development was documented in full and put aside, and the Navy evolution occurred through the Emerson into other forms of equipment and finally into the Drager, which is now called a LAR-5. The now conventional Navy oxygen re-breather used by the SEALs is the Drager LAR-5. It's been in operation for almost 15 years now. It's a long period of time we're talking about.

It began as a submarine escape apparatus, but it had a manufacturer that knew how to make that kind of equipment, so it kept going. Finally the Navy slid over, and once we stopped worrying about whether our source of supply would exist if there were another war. We stopped worrying about that and decided it didn't matter what the source was. We took the best we could get where we could get it, and that happened, and the LAR-5 was the best, and it is good.

INTERVIEWER: You were involved in a project with both the USS *Grouper* and the USS *Quillback*. What was that all about?

DR. LAMBERTSEN: First, with the green UDTs, the good surface swimmers who had never dived, I was to make them good underwater breathing apparatus swimmers and self-contained divers. That was done in Little Creek, Virginia. Then, promptly, to make them more operational,

we had the submarine service provide the *Grouper* with which to train them in locking in and out of submarines on the bottom and underway. That was where the *Grouper* came in.

It was in January of 1948 that they got underwater training and their diving training. Immediately we put it to work, and it was always Fane and me doing it together. It was not something in which he was an administrator. He was right in there with them as a swimmer. He was the first trainee and the first everything else. From going from the *Grouper* and having them learn the lock-in, lock-out sort of activity, there was the need to try to have them learn how to work with the *Sleeping Beauty*. That happened in the fall of 1948.

By that time, they had been through a lot of things in the Navy. They were taken up to New London, to the submarine escape tank and used that as a place to train. They were learning how to lock-in and lock-out and practicing so that we didn't have to have a whole submarine. You could run people through again and again and again until they get so used to it that it became so easy that it was natural.

They then went to the *Quillback*. With the *Quillback*, the task was to have them do heavy work on the deck of that submarine. We used it first on the bottom and had them go through handling the *Sleeping Beauty* and learning how to secure it and getting used to the thought of it. Some of them trained a little bit in the use of it as pilots. Some of them trained to become the trainers of the pilots, the maintenance and such things.

Having done that, we had the opportunity to go back to the *Quillback* and do a long run on a straight course in order to demonstrate coming down on the submarine and landing on the it, and having a small two-man deck crew positioned to help secure that submersible and demonstrate that, and then have it take off and demonstrate that. But the key to it was taking two people, Fane being one, and teaching him to be an underwater cameraman, and we had one of the few underwater cameras in existence at the time, I think. The inventor of the underwater

camera was Fenamar Johnson and he was a neighbor of mine. He had been taught to use the SCUBA equipment for the first time while he was down with the submarine.

They sat in the gun chairs of the *Quillback*, and the cradle for the Sleeping Beauty was up forward. Each had cameras, and each had fifty feet of film and a single shot with a line from the bow to a buoy, about a submarine length to a buoy. The requirement was to have the *Quillback* come up and the Sleeping Beauty, which I piloted, come in from the side as the submarine approached. We then had to thread a bowline through a loop in the buoy and hang on for dear life to that bowline while the tanks were vented and by using the diving plains to go down and sweep over the bow over the rail of the craft. We also had to have the help of one of the crew members pulling on the snared line and into the cradle, tying it up quickly, and then untying it and taking off again. That was the *Quillback*. The point I'm making is that the deck crew was the thing that made it work, because even coming over the rail, I lost a stern plane. It hooked on the rail and ripped off.

The main point of all of that was that it demonstrated in one shot with two good guys on the cameras that it had happened. Once that had been done, the film became the message that was sent by Fane and me with reports up into the system that then acknowledged that it existed and that something could be done.

The key guy in that whole thing, I think, was Admiral Fife. The reason he was key was that through all that kind of an operation, with people outside that submarine and all those things happening, that was hard work going on there, and hard work meant more oxygen pulling and more of everything. It was touch and go.

He, on occasion, rode that submarine when things of that sort were happening, not that particular one, but he did that, and he did it with his neck out so far, because there was no communication between the inside of the submarine and the outside of the submarine. Nobody

inside knew what was going on outside. They only knew that the periscope had signaled an okay. The submarines came in from the side, and if they swung around, they wouldn't see it. That was all the information they had. Men could have been swept over, had convulsions, passed out or had equipment troubles. There was just no way to communicate. Those people, the skipper of the submarine, and the admiral, who stuck his neck out, I think, were real characters.

People like Fane were doing that as though it were nothing. We were just doing it, because by that time he was a good expert, confident swimmer like the rest of them. None of them were in any way non-confident, and he, as a person, had his neck out, too, because, after all, he was the skipper of the team. The only one who didn't have his neck out, I guess, was me because I didn't belong to anybody. I know that was all. You asked about the *Quillback* and I gave you a story.

INTERVIEWER: Yes. As far as you were concerned with your career, did you go further with the Navy in doing that kind of work at that point?

DR. LAMBERTSEN: Yes. I went down two paths. One was to stay with the teams on both sides of the country because it had to be transferred over to the west coast. They were two separate things, two separate fleets. Yet, we had the beauty of having west coast people train with the group. The communication was always great with anybody who was in that team. I had free wheeling communication, even though I was back in Philadelphia.

I stayed with them for almost 15 years. At first, helping one skipper of the UDTs after the other with the tasks that they had, I would simply go down as an advisor or an unofficial friend, or whatever. I knew them all. They would come to Philadelphia for communication, as I had a laboratory there. That never disconnected.

Then, the big connection was to try to stimulate the improvement in the ability of the equipment to work and the understanding of what the stresses were on the people so that the

dangers were lessened. I set up laboratory systems to study the kinds of underwater activities. That sort of thing became broader because of the implications that the studies had on other things. It had therapeutic implications, for example, in medicine.

INTERVIEWER: It had implications for hyperbaric medicine, and that type of thing?

DR. LAMBERTSEN: Yes. It had implications for that, anesthesia and aerospace aviation. It became a very broad relationship over a number of years.

INTERVIEWER: Was there really a medical thread that went through everything you did, from the very beginning?

DR. LAMBERTSEN: Yes. That's right.

INTERVIEWER: [Does it extend] all the way to what you're [doing now?]

DR. LAMBERTSEN: That's right. Eventually, it became a very strong one that caused the Navy medical department to begin to send its special submarine medical and diving medical officers to my place for a year or two for joint study. We had a flow of people who were not operators in a UDT or fledgling Seal system, but rather in the medical department. They then carried it back, and I think I had about 15 naval medical officers who came through the last one only about four years ago.

INTERVIEWER: Did you ever do any work with George Bond way back then?

DR. LAMBERTSEN: We had good, normal communication among equals and that kind of thing. I didn't work with him, but we had good communication. He liked to, as I did, talk over these things. I was not on what you would call a team of Navy people working on the initial Navy saturation diving effort. The fact was that once it became a difficulty for them, I had to go through the task of setting up a separate operation at 400 feet and doing a saturation run there with only two people and a very simplified system. That was done together with a person called Edwin Link. He and I joined forces to do that task. As soon as it was over, he forgot we were

involved.

INTERVIEWER: He had a business interest, I believe?

DR. LAMBERTSEN: He had business interest. That's right.

INTERVIEWER: During your work in the 1960s, you stayed at Penn. Was Penn your home and where you did all your work?

DR. LAMBERTSEN: It had to be. I had no choice because once I built the laboratory there, there was nothing else like it in or out of the Navy at that point in time. As a result, I could not walk away from the laboratory and go somewhere else. I did get away for one short period, around 1951 or 1952, for the only sabbatical I've ever had in my life, and that came at a bad time, as far as the Navy under water team evolution went. We got together again.

INTERVIEWER: You had other duties at Penn? You had teaching responsibilities?

DR. LAMBERTSEN: Yes. I was a full-time career person in the university, and it was in the medical school. I taught pharmacology. When you did that, you did it for several months a year, and then you did research for the rest of the year. The research and teaching were interwoven.

INTERVIEWER: You did a lot of work with breathing. Did the National Aeronautics and Space Administration (NASA) really get much from your research, or were they off, starting from scratch on their own? Was there any cooperation between you and NASA?

DR. LAMBERTSEN: Yes, there was. NASA started from scratch. The Navy had been around a long time, and so it built on itself, but NASA had to build from nothing. As it formed it had to reach out and get people who were skilled or experienced. It reached out to the Navy, and first thing you knew, NASA was made up of Navy, Air Force and Army people. Medical officers were one component of it, and there were mathematicians and others, such as astronomers. Those people all knew me well, so we were all partners. Those Army, Navy, Air Force medical officers and I formed an informal group in which I was named as the head of the National

Research Council. It was a space science board and a major unit of the National Research Council, and I was the medical member of the Space Science Board. Therefore, they asked me to form a committee on man in space, and I reached out to and used those skilled external people to generate support for NASA, meaning to generate skilled judgements and information. There's too much of the story there and you don't need all that now.

There were eight panels of eight people each that set up a research program for NASA. That came out of their assumption that if those kinds of personalities could help make undersea work, they ought to be able to help aerospace things work, as well, and it was a good philosophy then.

INTERVIEWER: Doctor, when you talked earlier about some saturation work you did with a pair people at 500 feet, was that before or after the termination of SeaLab III?

DR. LAMBERTSEN: It was before. They had done a 200-foot run successfully. The pressure for doing the 400 foot run was from Link, who was a competitive character and very self-oriented, and he only came to my place for help when he couldn't make it work. Once he came, it seemed sensible at that point, since my laboratories were being torn apart in order to rebuild them. It seemed sensible to go ahead and have a field operation, so I joined forces with him. I didn't initiate that project. We just made it work. By having my people, I was able to get a chamber manufactured specially for the project, and that was the sort of thing that Link loved to see happen. He didn't like to spend his own money.

Since I was a consultant to the union, I was easily able to get them to manufacture a chamber that would allow us to bring up the saturated people from the bottom and tie them into a deck chamber, which I called the 'deck decompression chamber.' That was the first deck decompression chamber, and we chose 400 feet because I couldn't imagine there were any good reasons for not doing it at 400 feet. Helium was helium, and the general point was that it was

necessary to keep control of that operation on someone else's ship, and that led to a very interesting relationship between me and Edwin Link, who was not used to having someone else in charge on his ship.

Yet, if it hadn't happened that way there would have been extreme safety hazards. I actually went and checked out all the equipment and the chambers on his ship, and my crew became the operators and did the studies of the subjects in my laboratory. It was a joint project, but the performance of it was done from Philadelphia from my laboratory, as was the safety aspect and the scientific component. As soon as the operation was over, the words 'University of Pennsylvania' were removed from the National Geographic story. It became a Link operation. That was worth putting down for fun.

INTERVIEWER: Did you consult also with John Craven at the Deep Submergence Systems Program (DSSP)?

DR. LAMBERTSEN: John Craven and I did not consult. We talked to each other. We were kindred spirits and had a lot of communication, because of a lot of, again, mutual respect, I think, and it's still there. You asked why we did it at 400 feet or what?

INTERVIEWER: Yes. What sort of thing did John Craven need from you, based on your experience with breathing and deep submergence?

DR. LAMBERTSEN: What did John Craven need? Are you talking about later on, after the Polaris development and so forth?

INTERVIEWER: Yes.

DR. LAMBERTSEN: You mean under the subversive activity?

INTERVIEWER: Yes.

DR. LAMBERTSEN: I didn't have anything to do with that.

INTERVIEWER: Did you have much to do with any of the SeaLab projects?

DR. LAMBERTSEN: Again, since Doctor Workman was one of my students, and he worked in my laboratory before getting involved with Doctor Bond, it's obvious that we were in a lot of communication, but I had no role, no authority, no direct relationship to the projects. At the end of it, after it had its usual problems, people got called on to be part of a review group. I was part of the Smithsonian's review of the project. That's all.

INTERVIEWER: The 1960s were when the SeaLabs were in operation and a lot of the work that John Craven was working on. What were you working on? What of research had you involved yourself in at Penn?

DR. LAMBERTSEN: I think of the largest thread was on oxygen itself, without regard for what it was used. There was so much time spent on using the oxygen breathing apparatus and studying people as astronauts, in terms of whether they could breathe oxygen at a low pressure that didn't poison them and not have their lungs collapse. All those kinds of applications to operational things were in the background all the time, but so was the use of oxygen as a therapeutic agent and as a substitute for inert gases in high-pressure exposures. That helped extend our ability to dive without decompression or extend the dive without having so much decompression and to prevent the bends. Oxygen is everywhere.

INTERVIEWER: Was it really the chemistry of oxygen you were studying?

DR. LAMBERTSEN: No, it was the many things that oxygen does. It's a physical displacer of other gases in you. It has physiological effects that are not chemical. It has toxic effects that are chemical and may be similar to the physiological mechanisms that they act on. The main thing is that it's a life substance, and as such, no matter what you do in studying oxygen, it's going to last forever, whereas equipment is going to come and go. Any information that's learned about that element in our shared life system, which is the one that is life itself, [is greatly valuable]. That's your life fire, or flame.

Part of it has always been that the fascination with oxygen as an element of living mammals and humans, so most of what we've done is improve the ability to make use of oxygen without harm, how to interrupt the toxic processes so that you can keep going. We've studied and devised means of alternating the use of oxygen and not using it so that you need equipment that allows you to proceed and get the benefit of oxygen without coming up against some ultimate barrier. Then, you try to take all of this information and put it together as a data system so that other people like what you do. You're making a data system of taped conversations. What was necessary, I feel, was to build a data center not of odd papers here and there, but of the fundamentals of this information. They will then be available, permanently, to individuals who aren't able to repeat these experiments, because we're not going to be able to do over again everything we have done in the past. It won't be allowed or it won't be affordable. Saving the data and putting it together such that it can be made use of is a big part of my own life. For some purposes, it's the other end of the extreme, hypoxia, or not having enough oxygen. That's the high altitude.

We've had expeditions on which some of our people have gone to Mount Everest for physiologic reasons. In aerospace work, the emergency in an aerospace system, wherein you may lose gas and not have enough oxygen pressure to stay alive, has to be prepared for. There are things that can be done to try to improve the timeline of that failure so that you may have time to get out from under it again. One of those is fire in a closed system, which is really hell on wheels, as you can imagine, and yet the fire is oxygen burning something. To be able to put out fire in a space in which you are, without putting yourself out at the same time, is a part of the work that we've done.

We're generating ways to use carbon dioxide as something that doesn't just make you breathe more and make you uncomfortable. It makes you breathe more and helps your breathing,

especially making your blood flow in spaces better so that your brain works longer, so you can keep a brain functioning with a little carbon dioxide while your atmosphere doesn't have oxygen enough to sustain you. You are able to think and act and do things. These are related to diving, to aerospace work and to just plain fire fighting. Oxygen is a life substance, and we need it, and sometimes we can help sustain ourselves. At other times, we poison ourselves and disappear.

INTERVIEWER: Do you have any last thoughts? Is there anything that I may have asked you that you didn't think I would?

DR. LAMBERTSEN: How in the world do you get people to not talk so much around the barn when you're trying to find something out? I know this is unusual for me. I don't have much chance to do this kind of talking.

INTERVIEWER: Thank you. Thank you very much for spending time with us.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF CLAYTON DECKER

Kensington, Maryland

April 2003

## P R O C E E D I N G S

MR. DECKER: My name is Clayton Decker. I was born and raised in Peonia, Colorado. My grandparents had a cattle ranch there, and I was born on December the 12th, 1920.

INTERVIEWER: You were born on a cattle ranch in Colorado. Wow.

MR. DECKER: Yes.

INTERVIEWER: I was raised in Queens in New York City. They didn't have much of that there. Can you tell me what it was like to grow up on a cattle ranch? I haven't the foggiest idea.

MR. DECKER: Well, it was interesting In Colorado we have, you know, the Rocky Mountains running right down through the middle of the state, and so we experience all four seasons fully. As a matter of fact, the little valley in Peonia that I came from is referred to as North Fork Valley. My grandparents settled in that little town in 1882, and there I was. I graduated from high school there and was raised on their cattle ranch. In 1940, I graduated from high school. I married a high school sweetheart right after I graduated. I attended agriculture college in Fort Collins, Colorado, for two years. When the war broke out and Japan bombed Pearl Harbor, like many of the other college students, I wanted to go and fight for my country. I discussed it with my wife, and it was agreeable with her. At that point in time, we had a youngster who was a year old.

Then, I had to make the decision as to what service I should join. I used to think about the Army. I thought, "Well, I like hiking, but I didn't know whether or not I wanted to do that much hiking." The other thing that I had heard about the various services, if you were going to join one of them, was that you had to take two main things into consideration. One was a nice, warm bed, and the other was the chow, and I thought, "Well, now, if I join the Navy, I'm going to have both of them right along with me wherever I go."

I selected the Navy. In Colorado, in Colorado Springs, we have the big air academy there and so forth. I said, "Well, here I am on a cattle ranch." I'd never ever flown in an airplane. The closest I'd ever come to riding in an airplane was a roller coaster ride. I joined the Navy then.

INTERVIEWER: Let me take you back, before we move into the Navy, to your years on the cattle ranch. I'm from New York City and I know what different kinds of asphalt look like, but that's about it. You had just come out of high school, and you were on your cattle ranch. Tell me, what you saw around you; what did it look like?

MR. DECKER: Well, of course, it was beautiful, the country itself. Mount Lamorn looms right there, and then, we ran about 1,000 head of cattle, and a lot of people have asked me, "Well, what did you did with those critters in the winter time?" That was a good question.

Each fall, before winter set in, you shipped cattle, and of 1,000 head of cattle, we would ship around 400 every fall. It still meant you had around 500 or 600 head of cattle that you had to feed all winter long. That was the biggest chore during the winter months. All summer long, we cut hay. We stacked it. The time I was on the cattle ranch was before baling ever came to pass. We'd stack haystacks and have to take it out daily and feed it off what we called 'slips' or 'sleds' because there would be snow on the ground. The other thing was all the chores we had to do on a cattle ranch. I was about three miles outside of town, and went to school in town.

We also milked cows. Unfortunately, my grandparents never knew much about dairy cows, so we'd get those wild range cows. They'd have a calf, and we'd bring them in, and believe me, if you wanted to milk a range cow that didn't want to be milked, you had to almost hobble her. Well, you did hobble her and put a pole along side of her and everything in order to milk her. My chores, morning and night, were milking two cows daily. I got my chores done in the morning, got my books together, and headed for town. Often, I'd have to walk, and it was close

to a three-mile walk. I did have an auntie who was a teacher and I would ride with her occasionally.

It was a great experience. I just turned eighty this last December, but when I look at the experiences that I had as a youngster, I often think, “Oh, how I would love to have had my youngsters grow up in that very same environment.” It was slower living, but we had everything. We had a great school system and a hospital about thirty miles away. Delta was the county seat in Delta County. We experienced everything that people did in the big cities, but that country living was great, and I missed it after I left. Now that I'm eighty years old, my present wife and I get over to my old hometown of Peonia every opportunity we get.

INTERVIEWER: In school, were there any teachers you remember who were particularly good, or people who excited you about learning or intrigued you about the larger world?

MR. DECKER: Yes. As a matter of fact, when I was in school, before I went to college, during the last two years of high school in Peonia, Colorado, I decided I wanted to be an animologist. There was a deputy state animologist out of Denver, which is the capital of Colorado. There was a deputy state animologist living in Peonia who ran an experimental orchard to study moths. I thought, “Oh boy, he had me talked into becoming an animologist.” He said, “Hey, Clay, you get a degree in animology. You can go to work for Standard Oil Company and you can wind up down in South America at one of these big oil companies as an animologist.” Boy, that was for me. I mean, in the little hick town of Peonia, Colorado, the highest paid job in that little valley was a job in one of the two coal mines just up the river about ten miles. The boys who worked in the coal mines made pretty good money.

But during my junior and senior years of high school, I worked for Harry Newton, the deputy state animologist, and we ran moth control traps. In other words, there was the life cycle of a moth and a lot of people wondered when you were to spray fruit to prevent worms from

eating apples or pears. Well, they had to be told, and the state animologist would be the one that would tell them that.

We ran what we called 'traps' through the orchard. Every morning before I'd go to school, I'd go down and run the traps. We'd find out when the moths were flying at their peak. We figured that in about eight days following that peak flight was when they would lay their eggs. They were laying eggs while they were flying and those eggs would hatch. If the farmers or the ranchers on those orchards got that spray on their fruit then, as soon as that worm came out of that egg and took its first bite, it was going to get a bite of poison and it'd be gone. Oh, I thought that was great. I went up to Fort Collins after I graduated from Peonia High School and I did take animology, and there, another person who encouraged me was George Stafford. He was assistant principal, and he was a biology teacher. He really encouraged me to pursue animology, also.

INTERVIEWER: Did your family, your new family, when you married and had your first child, stay on the same farm with your grandparents? Did you work the farm as a family?

MR. DECKER: No, we didn't. The lady I married, the young lady that I married, her father was a coal miner, and they lived up the river about ten miles in the little town of Somerset, Colorado. After we were married, we lived with them. We moved in with them in Somerset. I got two years of college in. But in the summertime then, after I got to college, in order to make some money, I had to mine coal. The only money that really you could make of any consequence came from working in the coal mines. The two summers of the two years that I did intend college, I worked in the coal mine there at Somerset. Of course, fortunately, that was one of the things that helped me get in the submarine service, too. If you work in a coal mine, you certainly can't have claustrophobia. I worked in the coal mines, and, as a matter of fact, our son was born in June of

1941. Back in those days, and people today don't even believe this, you'd call a doctor and he'd make a house call. He'd come to the house, you know.

Well, when my first wife was ready to have this child, he not only came to the house but she had the child on the kitchen table. I helped by giving her the mask over her face. I mean, it's hard to believe, but there again, I'm eighty today, but if you go back a good number of years ago, that very thing still happened.

INTERVIEWER: What's it like inside a coal mine?

MR. DECKER: It's spooky. The job that I had was interesting. I was in the coal mine those two summers that I worked, which were the summers of 1941 and 1942. People don't realize it. In Colorado, they were called 'slope mines.' In the eastern country, they were shaft mines, but in Colorado, they were slope mines. Only four people each night would go in on what we called the 'graveyard shift,' so that meant that I went in around five or six in the afternoon and I got out around one or two in the morning.

The spooky thing about it that a lot of people don't realize, is that at midnight you have, because of the nature of the chemicals and metals and so forth in the mountain itself, the biggest change. It's sort of like the rumbling of an earthquake. Around midnight, the coal mine will do that. We used the term 'bumping.' I mean, it will actually bump and shake, and if you are up on the face where they were digging the coal, often times that coal would fall in front of you. My job was to go to the very bottom, two miles on the slope down in that mountain. The first thing that I'd do was to go clear to the bottom daily. I had charge of the big water pump.

They had a big, huge electric water pump, but the pump itself, of course, was driven by an electric motor. The pump needed a packing lens packed on a daily basis, and my job involved this old rope packing. I'd take the nut off the old rope packing, I'd put new rope back again, put it in and start it back up again. Of course, you wore a light on your cap, or your hat. In some places

in the mine, the ceiling was low. You'd actually have to stoop. Every passageway had a track, so you walked the track. You stayed on the track. So many people have a misconception. They think that in coal mines, because coal is black, everything is black. It is not so.

There were four of us who went in. Another chap was called a 'rock duster.' They used a dust, which we found out later was really bad for your lungs, but they called it 'rock dusting,' and it was white. It looked like flour, like the stuff your mom used to use to bake bread with. You had a paddle you'd put on your hand, and you'd just scoop this rock dust, and you'd throw it against the wall. You'd throw it on the ceiling, and you'd throw it on the deck, or the floor. The reason was that they were feeding air into that mine constantly. That one main passageway, where air was blowing in from outside, had huge big fans, and there was another exit where there was a big fan sucking it out. You had a good flow of air down in there all the time. Well, something happened if they did not put that rock dust on that coal dust. It never happened during the time that I was there, but I was told that a fire could start by spontaneous combustion. You could actually get an explosion if that rock dust got to flying around and igniting itself, so they put on the coal dust so that it did not do that.

They also had what they called a 'shot firer.' That man would come in with us during the graveyard shift and drill a hole. The boys that worked that day, for the last duty of their shift, would drill holes where they wanted the coal blasted. They didn't do any blasting. They would fill the sandbags, those little round bags about as long as a yardstick. He put a stick of dynamite in those holes, tamped it, put in the little bits of paper bags, stuck them in there and tamped them, and backed off a couple hundred yards and actually blasted that face of it for those boys. That coal was all down for them to do their work when they came on shift. He was called the shot firer. There were huge rooms in which they got coal. When they cleared out of a room and pulled

the tracks, as they pulled the track, to hold the ceiling up, instead of having to build fillers, they would leave big pillars of coal. You could reach around them

The last man who went down with us would go in and chop at those pillars. He had one mule. It was called 'stump pulling,' and he'd go in at night and pull the stumps. It was just the four of us who would go in at night.

When I would finish my job packing the lens on the pump down in the bottom, I would come up, and then, since they had electric motors, those electric motors had to be put on charge. It meant that I had to check the batteries, add water to the batteries if needed and put them on charge. Then, if I had any time left, I would go and help the rock duster a little bit to finish off my full eight hours down the mine on my shift.

INTERVIEWER: It sounds like they kept you busy.

MR. DECKER: Yes. It was a great experience, though.

INTERVIEWER: I take it that it was in 1942 that you discussed with your family the prospect of actually going to war?

MR. DECKER: Yes.

INTERVIEWER: Perhaps the warm, dustless bunk and good food attracted you to the Navy, aye? Where did you go to sign up for the Navy?

MR. DECKER: I joined the Navy. Of course, actually, there was a recruiter who came to Peonia, and I joined the Navy with him, but I was sworn in over in Denver. Of course, when I joined with this recruiter, a Navy recruiter, who came to Peonia, there were four of us who joined at the same time. He gave us chips to ride the train, the four of us, into Denver, and we joined after we signed up when we got to Denver. It was Christmas Eve, 1942, when I got on a troop train to go to Farragut, Idaho, to boot camp from Denver.

INTERVIEWER: They picked a bad day, didn't they? Well, it was war, I guess. You went to Farragut, Idaho, to boot camp?

MR. DECKER: It was a brand new camp that they had set up there.

INTERVIEWER: I imagine it would have been.

MR. DECKER: I'm sure you've heard of it.

INTERVIEWER: Tell me what boot camp was like.

MR. DECKER: As a matter of fact, at Farragut, there were actually seven camps in the Farragut complex. The camp that I was in was called 'Benyon.' I don't know who represented it, but probably someone who was a naval officer would be my guess. I can't remember. But I was there for three months.

Then, we were asked, "Have you given any thought about what do you want to be?" If you'll recall, back in those days, right arm ratings pretty much meant activities in the Navy, activities that pertained pretty much just to either boats or ships. I say 'boats' because, if you'll remember, we called submarines boats. Left arm ratings, you know. I just wasn't that well acquainted with it, and I went with the right arm rating and asked to go to torpedo school.

Little did I think, at the time. I didn't understand it well enough. I'll tell you what happened later on. After all, what did a torpedo man do after he got out of the Navy? Who was selling torpedoes or buying torpedoes, you know? I ended up being a left arm rating, but I did select a right arm rating. I selected torpedo school. From Farragut, Idaho, I was sent down to Norfolk, Virginia.

INTERVIEWER: Let me ask you to pause for one second. Getting back to Farragut for a moment, it was just carved out of this little place in Idaho as a training base. What did it look like when you got there? What did the base look like?

MR. DECKER: Well, I came from Denver and the Rocky Mountains. Denver is referred to as the 'Mile High City.' Somebody was telling me to go east, west, or north. Hey, the one thing about it is if you're around Denver or Colorado Springs or what they call a 'front range' and you lose your direction, you look towards the mountain. You know you're looking west if you look up and see the mountains. You can say, "Hey, that's west, sure enough." In Colorado, we have what we call 'foothills.' You leave the plains, but Denver is considered a mile high. I don't know, but the fourteenth step in front of the capital building in Denver is a mile high, and it has a big plaque there that says you're a mile high when you stand there on that step.

If you go west, the first things you encounter are foothills. You start climbing, and then you get up into the high country. Well, at Farragut, that really surprised me, coming from the mountainous country. When you get up in Farragut, the ground is flat, and there's a mountain over there, and it's flat, and then there's the mountain. There are no foothills, no nothing.

I got along fine at Farragut. I was there for three months, and I got some good training. I can remember writing my grandmother a letter back on the cattle ranch. I wrote, "You know, grandma, this place is so neat and so clean, but I didn't realize that I'm the guy that's having to keep it that way." I learned to wash my own clothes, make my own bed, and a lot of things that I hadn't had to do before.

Believe it or not, fellows, I was there for three months and I don't think I saw the sun shine over a half a dozen times. It was kind of depressing, I guess. That's the word. It was kind of depressing to me. Clouds hung low. It was overcast most of the time, and it was, of course, snowy. It has winter months there. There was a little town right by Farragut. The only nearby town of any consequence was Spokane, and if you got a 72-hour liberty pass, you could get into Spokane. They didn't have a USO in Spokane.

I made one trip to Spokane, but again, I was married, had a two-year-old son, and liberties didn't mean as much to me as it did most of the other guys. I was kind of glad to get out of Farragut and head for Norfolk, Virginia, on a troop train, a big troop train.

INTERVIEWER: How old were you then?

MR. DECKER: I was born in 1920, and all this took place from December of 1942 until about the first of March in 1943. That was when we went down to Norfolk.

INTERVIEWER: You were 22 years old. Tell me about going cross-country on a troop train.

MR. DECKER: That was a good experience. I enjoyed that. I really did because, again, I was from in a little cow town like Peonia, Colorado. I was on the train with all these guys and treated royally. We would stop and get lunch, wherever we might stop. Oh, we made one stop overnight in Chicago, coming out of Farragut, going east, of course, and two of the lads who were in the group going to Norfolk had parents in Chicago. They got invites to go with them to their homes, but they didn't. We just pretty much stayed around the train there and spent the night there in Chicago.

Then, we went on to New York City. Again, we had a little delay there. It was the first time I had ever seen any big city like that. The biggest town I had seen up to that point was Grand Junction, Colorado. Well, I had seen Denver also, excuse me. I was familiar with it. But I mean, seeing Chicago and seeing New York was, for this cow town boy, a new experience.

Then, we went on to Norfolk and got involved with the torpedo school and the torpedo class, which was interesting. It really was interesting. There again, we would say, "Hey, we want to do our part." We were at war with Japan. We said, "Let's get with it." Of course, the one thing that I did do that I probably wished I hadn't done in Norfolk was getting one tattoo on each arm. Down the line, I'll tell you that those tattoos worked out favorably for me, and I'll tell you about that experience a little later. While in Norfolk, I got tattooed, one on each arm, and they both

have to do with Navy, except that one of the tattoos, though it doesn't show anymore, has my name, my first wife's name, Lucille, and my oldest son's name, Harry.

By the way, my son, Harry, my oldest son, in June, will be sixty years old. Anyway, the names have faded so that you can hardly read them. But I did get tattooed. The other thing that was exciting for me at Norfolk was that the torpedo class I was in was a class of 26 men, and believe it or not, I came out number one in the class. I had the top score in the class, and that gave me a rating of torpedo man third class from Norfolk.

INTERVIEWER: What sort of things did they teach you about the torpedoes?

MR. DECKER: While we were there, the steam torpedo, the Mark XIV, was the only one that we worked on. I didn't become acquainted with the electric torpedo until after we had made at least one patrol. But the steam torpedo, we learned all about it. We could tear that motor down and put it back together. We learned everything there was to know about that steam torpedo.

INTERVIEWER: How long did the class last?

MR. DECKER: The classes were all day sessions. Of course, there were no classes Saturday, and of course, no classes Sunday. In the Navy, breakfast was beans because, hey, the galley had to get squared away so that we could have parade day. Everybody was in their whites and out on the compound when they were called. Those boys in the galley had to have everything ship-shape for inspection.

Beans for breakfast? You bet. Saturday morning we had beans for breakfast. I enjoyed Norfolk. I made several liberties to town in Norfolk with the boys. Back in those days, you could get one of two things. Most popular in the pubs was either Valentine's Ale or beer. We'd go to town and have our share of that and then back to the base. It was late summer before that class was over. As I said, I was number one in the class, and so I was given a third class rating. Do we want to move on to the next stage, then?

INTERVIEWER: Yes, we do. Where did you head after Norfolk?

MR. DECKER: We were given an opportunity then. The submarine service was strictly voluntary, but we could ask for submarine service, PT boats, Navy air, as far as torpedoes were concerned, and I believe the other option was destroyer duty. Destroyers had torpedo tubes at the time. It was one of the four. Well, there were three other lads with whom I became very well acquainted with both in boot camp and at torpedo school. They and I decided we would volunteer for submarine service, and we did. Of course, that was just the beginning. They sent us from Norfolk, Virginia to New London, Connecticut. It was very interesting.

The very first person who interviewed me at New London, at the submarine base, was this chap who, right off the bat, said, "Why do you think you're qualified for submarine service?" I told him, "Well, maybe I've got a pretty good answer. I worked in a coal mine, and I think that would prove that I don't have claustrophobia." He said, "That's a good thought. That's a good answer."

I found out later that, as a matter of fact, they absolutely did check to find out whether I did, in fact, work in that coal mine. They found out that I did. Anyway, I was accepted. I was accepted into the school to become a submariner.

INTERVIEWER: What was sub school like?

MR. DECKER: I enjoyed every minute of it, I really did.

INTERVIEWER: Was there a lot of classroom time?

MR. DECKER: Yes. There was a lot of classroom time. It's interesting to talk to submariners from back in my era. They can remember the S boats and the R boats pretty well. By golly, when I went to sub school they had the old O boats, and I trained on an old O boat.

INTERVIEWER: Really?

MR. DECKER: We would go out on an O boat about once a week during the time we were going to school at the sub base. One of the lads asked me, "You don't have claustrophobia because you worked in a coal mine, but are you fearful that maybe one day that iron tube will wind up being your tomb?" I said, "Well, absolutely." I think that with every submariner, it has to go through his mind. It certainly did go through my mind that very possibly that that could happen. But my goodness, I really looked forward to my very first experience making the escape at the hundred-foot tower.

INTERVIEWER: I was going to ask you about that. Did you really look forward to that?

MR. DECKER: I could hardly wait to get involved in that. There was an instructor. I'm sorry. I don't remember his name.

INTERVIEWER: That's all right.

MR. DECKER: One name I can remember from the sub base belonged to a man who very interesting, in the days that I was there, and maybe you've heard this name before. He was Spritz, Charles Spritz. We called it 'Spritz's Navy.' Now, he was a Navy man. As a matter of fact, he was one of the divers who went down for the USS *Squalus*. He'd take the new recruits coming in, like us, and he had a battery of Marines. They had a brig and everything else, and believe it, he was a tough one on the young guys. Really, I've thought about it since those days with Spritz, and that man really made men out of a whole lot of young lads like myself, a young man off of cow ranch in Colorado. He really did. He knew what he was doing and how to control men and tell them to get up, brush their teeth, get going and that sort of thing.

INTERVIEWER: Was he a chief?

MR. DECKER: Yes, he was a chief.

INTERVIEWER: Tell me about your escape training for the tower.

MR. DECKER: There was one lad with whom I was with in the barracks at New London. His father, and I'll see if I can get this right, his father was, gee, you know, since I've become older, and I don't think it's Alzheimer's, but names are harder to remember. His dad was one of those guys who, when they built the Holland Tunnel, they called them groundhogs or...

INTERVIEWER: They called them 'hoggers.'

MR. DECKER: He was a hogger.

INTERVIEWER: They were hogs and sand hoggers.

MR. DECKER: His dad was a hogger. It was interesting to him because, if you remember, before they would allow us to actually go in and make the escape, we had to go into a decompression chamber. He used to tell us about his dad being a hogger, and that while working in the Holland Tunnel, they had to do that very same thing before they would go and put in a shift to work down there. The thing that we discovered in going into that decompression chamber was that you got a bang when they put that pressure on you. It's misconceiving to the average layman. You say, "Decompression chamber," but they put pressure *on* you, even though they call it a 'decompression' chamber.

Anyway, when that really got hot and heavy, you looked at somebody else and if they just smiled at you, you thought that was the silliest thing you had ever seen or heard, you know. The other main thing about it was that we were told the reason it was done. Let's say that maybe you went through the procedure just yesterday and overnight you developed a cold or a little ear infection or something like that. It would show up as soon as they put you in that decompression chamber. Well, that told you not to put that man in there and put a hold on him because something was not right. But the training in the chamber itself, man, I have to tell you, was the thing that saved my life, absolutely. The training in that escape chamber was what saved my life. You were standing in that room, in the escape chamber at New London. For those of you who

haven't done it, they dropped in a one hundred-foot column of water. You were standing in water. The thing that dropped down the center was what they called a 'skirt,' and it came down just about chest high. It filled you up with water up to the bottom of that skirt. When they opened the hatch and dropped that column of water, it was a little scary. You were standing there and it came up and then settled back down. It was the same experience as you got up in the escape chamber when you made it on your own.

Even though you built up the pressure outside to exceed the outside pressure by five pounds, when you opened that hatch, that water wanted to come in. The water right there would come up under your chin and settle right back down again. That was kind of a hairy experience.

There was another thing that really fascinated me at the time, and it was the early summer of 1943. I was going through submarine school in New London. There we were, with our lungs on, mouth pieces in, nose clamps on, and we'd wrapped our legs around the line, stopping at every knot, every fathom, every six feet, exhaling, inhaling, as we were told to. You had these lads who were instructors swimming around you, just in their swimming trunks and, if you remember, there were blisters on the side. They could swim into those blisters and get a breath of air and come back. Little did we know then that it was going to be the procedure down the line, the free ascent, or 'blow and go.'

It was interesting to me because, I would be looking up, letting the knots pass through my hand, and I stopped and hesitated and exhaled, and inhaled. Then, there would come one of those instructors right up to me. Of course, when you talk under water, the bubbles just come out. They said, "You're going too fast," or they might have come up and said, "Slow down a little bit." You could hear them. They'd come right up to your ear and then boom, they'd scoot back in for another breath of air, but they'd be right there watching you. It was a great experience, oh my. After my first time, I said, "Hey, let's go again."

INTERVIEWER: How long did it take you to make the full ascent, while you were training, all the way up the tower?

MR. DECKER: On the hundred foot tower?

INTERVIEWER: Yes. How fast do you go?

MR. DECKER: Well, we were told not to go too fast.

INTERVIEWER: Was it seconds or minutes?

MR. DECKER: Oh, it was a matter of a minute or two, I'd say. You hesitated just long enough to exhale and inhale. Now, another thing was that on your lung, initially you charge it. There is something else that I'm going to ask Captain Momsen, too, while we are here visiting. I'm told that after the initial charge, the little canister in that device is soda lime. Is that what it is?

INTERVIEWER: Yes.

MR. DECKER: It was soda lime and it...

INTERVIEWER: It absorbs CO<sub>2</sub>.

MR. DECKER: The reaction is that when you exhale carbon dioxide, the soda lime absorbs the free carbon and evolves free oxygen. In reality, after you use that initial charge that they put in the lung, you are truly on the straight oxygen of your own that you've exhaled.

INTERVIEWER: Yes, you're on your own breath. That's right.

MR. DECKER: It is interesting that during the time you're making that ascent, there are bubbles coming up from that exhaust valve all the time. It's because that external pressure is decreasing, so there are bubbles coming up out of it all the time.

INTERVIEWER: How long was sub school in those days? How long did you have to stay in New London?

MR. DECKER: It was a good three months that we were there.

INTERVIEWER: You would go out on one of the O boats or another training boat roughly once a week?

MR. DECKER: About once a week we'd go out on one of the O boats to get the feel of a dive and being down. I remember it happening. On a couple of occasions, even after guys would say that they were accepted, they went out on a boat, on a run like that, and they would come back in and say, "It's not for me." There was one lad, in particular, in the same barracks that I was living in, on the base there at New London. He just said, "Hey, it's just not for me. It's not for me."

After you were in and assigned to a boat and made a patrol, as I've told friends of mine, all you had to do was go to see the chaplain after a run and say, "Hey, mentally, I can't take it." There were no questions asked. You were out.

INTERVIEWER: What did the O boat that you went out on and trained in look like inside?

MR. DECKER: It was pretty, well...it's hard to describe it.

INTERVIEWER: If you compared it to, let's say, the later boats you went on, how did it look different?

MR. DECKER: It was just almost like night and day, really.

INTERVIEWER: It was much smaller, wasn't it?

MR. DECKER: Yes, oh yes.

INTERVIEWER: Did they have any on-boat accommodations? Did they have overnights when you went out?

MR. DECKER: No. There were none to my knowledge. No, we'd go out for a good part of a day and that would be it.

INTERVIEWER: I assume that they put you in the torpedo room and had you take a look at the way they used to do it?

MR. DECKER: Yes and no. On my first assignment, even though I had a third class torpedo-man's rate, from what you heard as an enlisted man, they'd say, "Hey, when you go as an enlisted man, I don't care if you've got a rank or a rating of any kind. You're going to do your share of peeling the potatoes and everything else. You can rest assured that on a first patrol, you're going to do it. Now, that's all there is to it."

I knew that was going to happen when I went aboard the *Tang*. Back in those days there were not very many boats that had Boatswain Mates aboard. They had a Boatswain Mate. We had a first class Boatswain Mate aboard the *Tang*. I went aboard and I met this lad. Remember that I was off of a cattle ranch in Colorado, and I swore that man must have been related to Hitler. He cracked a whip and basically, it was right arm ratings. We not only had a Boatswain Mate but we had a Boatswain Mate striker and he was kind of cocky, also. The first class Boatswain Mate knew the Navy manual and he could quote it. I mean, you'd ask him what was on page so and so, and I think he could tell you. That nice guy was one of the nine survivors, by the way, and we became very close friends. But I did my share of potato peeling. I stayed out of the way of the Boatswain Mates as much as I could, and I didn't ask to get off the *Tang*. But after that first patrol, I asked the executive officer if I could become a seaman first, and go back to the black gang. That Boatswain Mate is a wonderful guy, and we have a great rapport yet today. We e-mail back and forth, and he knows my wife, I know his wife, and he's got a beautiful home up on Palamar Mountain out in California. He stayed in the Navy and retired as a full commander.

Anyway, a very good friend, a very close friend of mine on the *Tang* told me, "Clay, if you break down first class, come on back to the black gang." I broke down, went back in the black gang and learned about Fairbanks Morse diesel engines. The *Tang* had Fairbanks Morse diesel engines. They were beautiful things, beautiful pieces of equipment in both engine rooms.

INTERVIEWER: The *Tang* was your first assignment right after school?

MR. DECKER: That's right.

INTERVIEWER: You put her in commission out of Mare Island?

MR. DECKER: We put her in commission out of Mare Island. She was built on Mare Island, California.

INTERVIEWER: Tell me about the *Tang*, under construction, and your being there as part of the first crew?

MR. DECKER: When I arrived at Mare Island, I couldn't go aboard the *Tang*. She hadn't been commissioned yet. They put us in the barracks and we'd go down, daily, to the *Tang* to do various chores and so forth, and we had oodles and gobs of civilian people. For instance, we had a Westinghouse maneuvering panel, so we had people from Westinghouse there. We had Fairbanks Morse diesel engines, so we had representatives from the Fairbanks Morse. We would just go down on a daily basis and acquaint ourselves with the boats, help wherever we could, stand watch down there and that sort of thing.

The chap who I mentioned to you about changing my rate, that was where I first met him. His name was George Lofkin and he had just completed five runs on the USS *Tunney* before being assigned to the *Tang*, and he was a First Class Motor Machinist Mate. George looked me up in the barracks at Mare Island, and he said, "Clay Decker, I understand you're married and you have a son who is two years old. I have a son who is two years old. Clay, I just bought a home at 67 Stoney Ford Avenue in San Francisco, and it's on one of those steep hills." Today you'd call it a condo, because if you go out to San Francisco and look, you'll see that 67 Stoney Ford is still there, but the house is split between next door with a common wall. A common wall divided this house from that house, and when you stepped out the front door, you were on the sidewalk. It had a back yard about the size of a postage stamp, but it had two bedrooms. He said, "Clay, I bought this house for \$5,200. I don't know how I'm going to pay for it." My wife was

out there in California. She was a secretary to the chief executive officer at the Kaiser Ship Yard, and she had hired a babysitter. He said, "Clay, how about you and I getting together? We're going to go out on the *Tang*. Your wife and your youngster could move in with my wife. We've got two bedrooms. My wife, Martha, is strictly a housewife. She could baby-sit the boys and take care of them. You and I are going to be on the *Tang*. Your wife could be out bringing in some of the beans." Boy, it just worked out perfect, and we did that.

When George and I went to sea on the *Tang*, our wives were living together at 67 Stoney Ford Avenue in San Francisco. Like I said, George was the one who helped me out then, rescued me from the Boatswain Mate, and we laugh about that, we really did. When we got into the prison camp, we got to know one another very well.

Anyway, George asked for this arrangement, and it worked out great, and we put the *Tang* into commission. We were out at Pearl Harbor, at the sub base on Christmas Eve, basking out on the deck of the *Tang*. It was January. I was looking up at the moon and the stars and said, "Gee, back in Colorado there's got to be a foot of snow on the ground, and here I am out here in beautiful Hawaii, on the *Tang*."

INTERVIEWER: Who was your skipper?

MR. DECKER: The *Tang*'s skipper was Richard O'Kane.

INTERVIEWER: Tell me about the first time that you met O'Kane.

MR. DECKER: He called us all topside, even before the commissioning, and chatted with us, because we came from all walks of life. Like I said, George Lofkin already had five runs on the *Tunney*, but he was brand new to O'Kane.

Dick O'Kane, I think, was an officer and a gentleman. There's no question about that. But O'Kane definitely used the chain of command. In other words, he didn't want just everybody coming to him with any problems, you know. He wanted us to go to the chief of the boat or the

executive officer, and rightfully so. I mean, he had enough on his mind. I'm sure that you've heard that Richard Heatherington O'Kane was a Medal of Honor holder, and I don't know where the title came up, how it ever came about or who started it. As a matter of fact, here at the Academy, one of the leading officers said to me the other day, "I'll never forget the first time I met 'Killer' O'Kane." He got the name 'Killer' O'Kane. People ask me about that and I say, "Hey, look, I don't know." They have to mean it jokingly. The man was married just like I was. The man had two youngsters and I had one. He didn't want to die any more than I did, but he was going out there to do a job. He had a job to do. I think we all have to agree that he and the *Tang* did one heck of a job. So many people don't realize it. They stop and analyze it in a minute. *Tang* only made five patrols, but hey, the *Tang* only fired torpedoes on four of them. On our second patrol, the Battle of Truck Island, we didn't sink a ship. In order to get a star and your combat pin you had to sink at least one ship. We never sank any ships on that second patrol, but we picked up 22 flyers out of the water. I didn't bring it with me today. I wish I had. Back at the hotel I have a list from the Navy Department that I've got a picture of them to show you. This year the VA made me a one hundred percent VA patient. The Disabled American Veterans, the DAV, helped do the paperwork for me. The lad who did it said, "Mr. Decker, are you aware of how many medals you're entitled to?" I said, "Well, you know, I have the Silver Star and the Prisoner of War, and when I go to conventions, I wear them on my little vest. I'm proud of them." He said, "You're entitled to 16. If you don't mind now, one of the things that happens when you become a one hundred percent disabled veteran is that the Navy Department will send you a copy of every medal you're entitled to," and they did that. One of them I got, believe it or not, was because of that second patrol, picking up all those flyers. It is black and white. I am a recipient of the Navy Air Medal. Now, how in the world does a submariner get hold of a Navy

Air Medal? But, fellows, I have one. It's there. They tell me I'm entitled to it, and so it's there.

That was interesting.

INTERVIEWER: What was it like being on patrol with O'Kane? What were his manners like?

What was the ship routine like?

MR. DECKER: Remember that on my first patrol, I was a Torpedoman and peeler of potatoes, and I did my chores and so forth. On my second patrol, I really saw more of the skipper than I did on the first patrol. Back in the black gang and particularly in forward engine room was where I had my station on second patrol, when I went back to black gang. That was where we had our two water evaporators below decks, in the forward engine room.

During most of the second patrol, I got to the point at which you could blindfold me and I could take one apart, clean it and put it back together. I don't think I ever did have both of them going at the same time, because one of them had to be down to be cleaned and so on and so forth.

That was one of the other things that put me on one hundred percent disability. I'm wearing this oxygen. So many people aren't aware of it, but hey, those World War II boats were just loaded with asbestos. The metal covering around the evaporator, when you pulled it off, showed a thick covering of asbestos around the hummer, you know. I cleaned one at least once a day, but more often twice a day I would clean one.

Anyway, Dick would come back, call a white glove inspection, if you wish, but he noticed things. He would tell you, "Good job, sailor, good job, good job, looks good, sailor, looks good." But he was all business. There was no 'ding donging' around. Never did I see him come into the crew's quarters and sit down in the galley or sit down on the table and just chit-chat. The executive officer, Murray Frazee, did. Bill Ballinger, who was the chief of our boat,

put five runs on the *Tunney* before he came to the *Tang*. Bill was one great guy with the crew. I mean, Bill Ballinger was just one of the greatest, as far as chief was concerned.

On that second patrol, I went to Bill first and told him, “Bill, I really think I want to be a Motor Machinist Mate.” “Okay,” he said, “I’ll get it set up for you to talk to Murray,” and I talked to Murray Frazee.” By the way, on the very first patrol, we took turns at bow planes and stern planes and that sort of thing, for some reason or another. Murray Frazee was executive officer aboard the *Tang* and he made floor patrols with O’Kane, as the executive officer. It was Murray Frazee’s job to select permanent bow planesmen and stern planesmen on the very first patrol. Anytime we were called to battle stations submerged, and it didn’t make any difference where you were or what you were doing, you’d drop what you were doing and go to your battle stations for which you were designated. He selected me. Murray is now retired. He lives in Gettysburg, Pennsylvania.

About four years ago, my wife and I visited him, and I asked him, “Murray, how come you selected me as bow planesman,?” Remember that I came off a cattle ranch, and the term, of course, is ‘catching the bubble,’ and you remember our bubble. We had an arc about as big around as your finger, the glass bubble and, for some reason or another, there I was, off a cattle ranch. He said, “You had the sense before anybody else. When that bubble started getting away from you, you knew to tell the diving officer to ask the man to pop some weight.” You remember the movie *Das Boot*? Remember how they shifted weight and sent men forward or sent men aft. Well, I apparently sensed it more quickly than other guys did. I was not going to be able to catch it with the bow planes. I’d say, “Give me some weight aft or give me some weight forward or whatever.”

I used to know the name of that one sub. You remember seeing pictures of it. It came up out of the water from a dive like that. That would put every man on his can back there on that

load, breaking the surface and taking it out like that. I never did that when I came up while I was on the bow planes.

I told Murray, “Murray, by making me permanent bow planesman on the *Tang*, on that first patrol, you really saved my life.” When we hit that convoy on the fifth patrol, one of the first things that O’Kane called for was for everybody go to battle stations submerged. It was two a.m. in the morning and we were still on the surface and everything. That has been the thing that’s been so confusing to a lot of people. What the heck happened? You were at battle stations submerged but were doing everything on the surface. That was exactly what the situation was. But I told Murray Frazee, “Murray, you saved my life because I was back in the forward engine room on the throttles. I was standing watch on the throttles in the forward engine room.” Word came over to go to battle stations submerged. I turned the throttles over to Zofkin and went forward. There I was, sitting at the bow planes in the control room at the front row seat whenever action took place on the *Tang*. I could open the hatch and go up in the conning tower. The ladder was right here. I could reach out and touch the ladder. There was the chart desk right there in the center of the control room. The Christmas tree was over there. The man on the water manifold was over on the starboard side. I just sat right there like this, not going anywhere. We had not called for a crash dive or anything. I was listening to everything that was going on up there with the fire control party. I knew exactly what they were doing up there. It was a front row seat, it really was, the one I had.

INTERVIEWER: Tell me what it was like to make an attack on the *Tang*.

MR. DECKER: The main people, particularly civilians, asked me, “What if you saw a ship? Would you see a target out there?” The World War II Submarine Veterans Organization, about three years ago, had a lottery-type thing, and I won a picture. It’s a good three feet wide and two feet high. It is a painting made by an ex-submariner, and it shows the sub, and the target was

smoke on the horizon. I mean, before you would ever see a target, why, you'd see smoke, because, remember, most of those ships were either oil burners or coal burners. If they were bending it on at all, boy, they'd give off a smoke stream that you could see for miles. Remember, on the *Tang*, in particular, if you were up topside, up on the periscope or as a look-out, we were told that our distance was seven miles to the horizon. I don't know what it was, as a matter of fact. When I saw the O boats, they looked so nice on the water, on the surface. The new nuclear submarines look like humpback whales to me. Of course, they don't stand topside watches anymore like they used to. Either radar or the boys saw smoke on the horizon. As a matter of fact, on that fifth and final patrol of ours, at two a.m., the targets were picked up on the radar, originally.

Like I said, I was sitting there in a front row seat. They called a fire control party, of course. I had been a Torpedoman, the thing for those of you who are qualified and have your submarine qualifying dolphins. On the O boats we were told that you had a good 5,000 lines, bows, gauges or something. When the qualifying officer went through that boat with you and he pointed to something, you'd have better known what it was. If it was a valve, you need to know what the valve was for and what it did. If it was a line, what went through that line? Was it air, hydraulic oil, water? Fortunately, I was exposed to torpedoes, and the fire control party would go up there and they'd talk about putting the data in the torpedo, "Run so deep and blah, blah, blah." That all meant something to me, probably more so than to a lot of the other guys, having been a Torpedoman.

On the same token, the thing that used to interest me the most was why the fire control party was so concerned about turning the gages until they put data into the torpedo. I didn't understand it until it was really explained to me. Of course, it was a Japanese vessel, or a 'maru,' a one or two-stacker maru with so many people. Understand that what they were doing was

figuring out how much water that vessel drew, because we knew how important it was to try to get the torpedo you sent hit it as close to the keel as it could.

INTERVIEWER: Well, there had been some problems with the torpedoes in the past, hadn't there?

MR. DECKER: Yes, exactly. Oh my, yes. Oh, the torpedoes. What a nightmare we had, really. Only on one patrol did we bring back a torpedo, and it had to be an electric one, too. But we had torpedoes. The sad thing was that on a target, maybe close to shore, the torpedo would go under the target and explode over on the beach. Really, I mean, our immediate boss, who was in charge of the submarine fleet out there was Admiral Lockwood. Remember, Nimitz was in charge of the Pacific fleet, but Lockwood was our immediate boss. Oh, we felt so sorry for him. Boy, he was pulling his hair. If I remember correctly, one of the trips that he used to make pretty frequently was to a torpedo factory. I think they were making torpedoes pretty close to Baltimore at a torpedo factory somewhere.

INTERVIEWER: There was one in Washington, D.C.

MR. DECKER: Is that right?

INTERVIEWER: Yes.

MR. DECKER: Oh my, he'd make trips there. That lad that talked at the dinner last night, Peter Maas, commented about dropping one off a cliff or something and figuring out about that firing pin bit. Anyway, we had our hands full with the torpedoes. But there again, getting back to the fire control party, I was told that when Richard O'Kane was executive officer on the USS *Wahoo* he did most of the periscope searching. He did so aboard the *Tang*. We really took our hats off to Admiral O'Kane. Those destroyers would be coming in right down the throat and he'd hang right in there and lay it to them and blow them out of the water.

INTERVIEWER: I just have a quick question, going back to the torpedo situation. When you arrived on the *Tang*, had the torpedo situation been pretty much cleared up? It was an earlier problem, but when you got there, you didn't have that many problems with torpedoes did you?

MR. DECKER: Oh, yes.

INTERVIEWER: You did still have problems?

MR. DECKER: I sure did, yes. Like I said, on the first patrol, it was not so. We got along pretty well on the first patrol. On the second patrol, remember, at the Battle of Truck, we never fired a torpedo. The third patrol was when we actually brought one torpedo back. Dick O'Kane said, "I'm going to take one back. I want Admiral Lockwood to see this hummer." I can't remember, even when we were in the prison camp, ever asking Dick about it. We called him 'Skipper O'Kane' and 'Admiral O'Kane,' but we got to know one another like Dick O'Kane and Clay Decker. It was interesting.

Many people ask, "Well, how well did you know Admiral O'Kane?" and I say, "Hey, look, the Japanese used to throw us in a tub with a bar of soap once a month. I took baths with him." On that one patrol, we brought that one torpedo back. Lockwood, bless his heart, was a wonderful man. He was a great guy. Admiral Lockwood, our boss, never missed being right at dockside any time we'd come in off patrol. He was right there to greet us, right there to shake hands with every man as he got off that boat.

INTERVIEWER: Tell us about that last patrol, when you encountered the convoy.

MR. DECKER: As you all know, they refer to submarining as the 'silent service,' and rightfully so, I guess. From our standpoint back then, we didn't want anyone, particularly Tokyo Rose, knowing where we were going. But until we cleared the torpedo nets and everything, why, we didn't open the orders to know where we were going.

When they opened the orders, the skipper would come on the intercom and tell us all where we were headed, where we were going on that patrol. He did so, even though we stopped at Midway to top off our tanks before we went on to the Formosa Straits. We were headed for the Formosa Straits. Submariners, back in those days, absolutely hated to patrol the Formosa Straits. Today it's called 'Taiwan' or the 'Taiwanese Straits,' but they were the Formosa Straits back in those days. I tell people, and anyone who knows a little bit about the geography of Pacific knows, that the Formosa Straits has, probably, the shallowest water in the whole Pacific Ocean. We knew, all of us, regardless of our rates or how many patrols we had made and so forth, about the Japanese, as far as their depth charging was concerned. It was just common knowledge. You took a 55-gallon drum, filled it half full of TNT and dumped it out in the water. It took in a little salt water, but it would only gain so much weight, and anything so heavy will only go so deep. They were not self-propelled.

The thing that we were most fearful of, however, whether you remember it or not, involved the pressure hole and flood valves. You had your vent valves on your bow tanks. When you went on patrol, it was not so when you were maneuvering and shaking down and you were back at port and so forth, you would use the flood valve and the vent valve both. But when you went on patrol, flood valves opened and locked open. The thing we feared the most was the depth charge going off below us, blowing those ballast tanks clear out of the water and popping us to the surface like a cork. That was the thing we used to fear most. We didn't mind them, too much, going off to the side or right above and so forth. I want to tell you something. The crew on the *Tang* went through some long, terrible depth charging experiences. We really did.

INTERVIEWER: Did it rattle the entire boat the way Hollywood would have it? Did it rattle the entire boat when they went off?

MR. DECKER: Oh my, yes, you bet. Just before they went off, they went click, click. You could hear them on the sub. They went click, click, and bang. Some people ask, "What did it feel like?" It was though you were in a 55-gallon drum with somebody beating on it on the outside with a hammer. Like I said to you before, there were some guys, who, with depth charging, in particular, just could not take it. They'd get in, go to see the chaplain, and that was the end of it for them. They weren't belittled or anything like that. It was just routine to be able to do it that way.

INTERVIEWER: Let's say you were undergoing an attack and there were people on the boat who maybe shouldn't have been there. What happened? Did you restrain them? What happened when it started?

MR. DECKER: No, there was no panicking or anything. It is so interesting. I haven't had anyone explain this to me, but it's interesting. Last year, in August, that Russian submarine went down on the east coast of Russia. The media got a hold of me immediately and, as a matter of fact, you might have seen me on Tom Brokaw's program. Anyway, you know, they were asking whether those guys were panicking down there. Well, I told them, "Look, if they were trained like we were trained, they weren't panicking." Even in that kind of a situation, they weren't panicking. We didn't panic. But the thing that confused me was that they were talking about those guys freezing to death. In many, many depth charge attacks on the *Tang*, if the bottom was 400, 500 or 600 feet below, we went to the bottom and shut down everything. There would be no air conditioning, no refrigeration, no nothing. Talk about silent running. That was silent running. But you could sit on the edge of a stool and bend over, and the water would run off your nose. It was hot, you bet. The only thing I can come up with is that on the boats that I served on, when we dove, they put pressure in the boat. They don't do that today. Is that the big difference, the fact that they put pressure in the boat? I understood we put pressure in the boat. The *Tang* was

supposed to be called a thick-skinned boat, but I understand it was still less than an inch thick. There was the pressure hole. Pressure in the boat may have been the reason for it. Sure, it was hot. You would think that if you were down there 600 feet, sitting on the bottom, it would be cold. The water would be cold. Well, I'm sure it is outside, but not inside. You just sat there and didn't move a muscle and the water would just run off of you.

INTERVIEWER: Did your boat ever go down that deep, down to 600 feet? Its test depth was 450 feet.

MR. DECKER: Have you read O'Kane's book?

INTERVIEWER: Yes.

MR. DECKER: You go back and re-read that. On our shakedown cruise to San Diego, she got away from us and we went down almost 700 feet. We didn't have any problems, thank God. We had a few little leaky lines and gaskets. It wasn't planned. Hey, as a matter of fact, if you read his book, Murray Frazee comments about it. The chief was our chief cook, or 'commissary chief,' I guess you could call him. I almost said his name. Anyway, we got to San Diego. There was no liberty. I mean, we had civilians aboard, you know. We had Westinghouse people aboard. We got to San Diego and I think we tied up next to the USS *Holland*. I can't remember for sure what ship it was. They didn't have a sub base, per se, back in those days, so we tied up and were there just overnight. No one got liberty or anything, and we went back to Mare Island. That chief, he was going to go over, and he was telling the chief of the boat, "I won't be back because we accidentally went down almost 700 feet." He was going to leave.

Now, you read the book again. Murray Frazee, the executive officer, said, "You'd better be back here tomorrow morning, or I'm going to put you before a firing squad!" He did, and it's in the book. The chief did come back, but that was the only run that he made. He made one

patrol on the *Tang* and got off her. You bet, we sat on the bottom many times and let them just go ahead. Have you ever had the experience of someone telling you about using CO2 absorbent?

INTERVIEWER: Yes.

MR. DECKER: That was a five-gallon can. You opened it, and it was vacuumed just like a can of coffee. You'd get those mattress covers, and excuse me for the Navy expression, 'fart sacks,' get them good and tight, and put that crystalline material on there. Hey, we not only did it once. We not only did it twice. We did it at least a half a dozen times. I mean that air just got so bad that you could just watch it. You spread it out on the mattresses and started to get light yellow, dark yellow, light brown, dark brown, and then you almost turned black. Of course, you could bleed out of your air tanks. You could bleed a little bit of air into the spaces then, which, being a motor machinist mate, was one of the biggest things that we were trained to do. Believe me, it was so bad that George Zofkin never made it because he was a Navy-trained man, and he didn't go to sub school. They needed men so badly that he got aboard submarines without having sub school training. But we were told that standing throttles, a diesel engine and a gasoline engine, needed two things to really function, air and fuel. Of course, ignition on a gasoline engine is a spark plug. Ignition on a diesel engine is compression. It's combustion by compression.

That wasn't in the *Blue Jacket* manual. It wasn't way down to him by any high technicians, but George had a big, heavy ball pin hammer. It was a good eight to ten pound hammer. It was a heavy baby and painted solid red. He fixed a clip on the starboard side, and you were standing, facing forward at the throttles in the forward engine room. Right there was that ball pin hammer.

If you went and checked the Fairbanks Morse diesel engines, the main fuel line going to each one of those engines came right up near where your controls were on your throttles. It came

up and made almost a right angle turn to go down to feed your engines. George had it figured out. Have you ever heard the term 'some diesel engines run away?'

INTERVIEWER: Yes.

MR. DECKER: You had a runaway engine. That was one of the things that we feared. George taught me something. He said, "Clay, I got it figured out. In theory, they either have to have air or fuel to run. If I get a runaway, all I've got to do is grab that ball pin hammer, make one swing this way, and hit its copper tubing. If I hit that baby right there, it will bust it. There's the connection, right there, a right angle connection. If you break that connection, there's no more fuel going to that engine. If you swing that way, and back that way, there will be no more fuel." We had our Christmas tree right up there. Have you seen that main induction back there in the forward engine room?

INTERVIEWER: Yes.

MR. DECKER: Was it about that big around?

INTERVIEWER: Yes.

MR. DECKER: When you worked through there and both those engines were running top speed, it would nearly knock you down. The air was coming in there so strongly. Of course, I belonged to this club. They wear one plug in each ear now, but back in those days we never had earplugs. We never had muffs or anything else. When both of those engines were at top speed, if you came into my engine room and wanted to talk to me, you nearly had to do sign language or get right up to my ear and talk.

Anyway, I was told that it wasn't that Christmas tree. When that diving alarm turned red, and if I didn't have those throttles down right then, each of those engines would only have to make about ten to twelve complete revolutions and they would break every man's eardrums on the boat. It would suck. It would take in that much air with that main induction closed. It would

take so much air to run those engines that it would pull the air out of the boat just like that. We never tried it, believe me. But there was the thoughtfulness of George Zofkin. He said, "Boy, listen. When I go back like this and those babies don't respond, I'm grabbing that hammer and I'm raising heck with those fuel lines." He was a great guy.

INTERVIEWER: At the end of the last patrol, when the boat was lost? What happened?

MR. DECKER: Of course, like I said, we got the orders. We were going to go to the Formosa Straights. None of us were particularly happy about that because of the depth of the water, but as it all turned out, it was, you know, in our favor that the water was as shallow as it was. On the morning of October 24th, 1944, at about two a.m., they picked up tips on the radar screen.

INTERVIEWER: Were you on the surface?

MR. DECKER: We were on the surface. I was a bow planesman, all the time. We attacked during battle stations submerged, and many times, we did it both from underneath and from above. We fired torpedoes, submerged, and we fired torpedoes from the surface, but for the most part, I could really watch everything that was going on when we were on the surface. I was sitting there at the bow planes. In that particular case, the one thing that struck me the most was that in previous convoys that we struck, we'd find two ships abreast. They would 'zig' X number of minutes, 'zag' X number of minutes and, of course, the job for the fire control party was to figure out those zigs and zags and time them, put the information into the torpedo, and send it on its way.

In that particular case, there were 35 targets up there, 35 ships, end to end, and they were all apparently going full blast. I mean, all of them, as I said, were either coal burners or oil burners, and the smoke was just rolling out of their stacks. Well, it was like shooting ducks in a shooting gallery for O'Kane. I was told whenever they'd hit a convoy, they'd fire six tubes forward and four aft. We carried 24 torpedoes when we went on patrol.

When they cleaned out the torpedo tubes, forward and aft, they usually got away from the action. O'Kane did it much differently. He got right in the action and would get close enough to the ships that the boys on the bridge said, after we'd fired all the six torpedoes forward and the four torpedoes aft, that some of those ships in that convoy were firing at each other. There were shells flying back and forth over the top of the *Tang*. Remember that if you go aboard a submarine today, practically all of it is done mechanically, in terms of loading the torpedo tubes.

Back in those days, those boys had to do it with a block and tackle. Be it on the surface or be it submerged, you had to have the boat. You had to give those boys a break. You couldn't be going up angle or down angle or doing a lot of maneuvering because it took them a little while to get those tubes loaded again. When we got in there on that first round, O'Kane decided that the hunting was great. It wound up that in that convoy of 35 ships, we sunk 13 of them. The thirteenth one was a troop transporter.

We found out later, after the war, that the convoy wasn't two abreast and wasn't zigging and zagging. If you check the time data, it was just prior to our landing at Leyte, back in the Philippines. We understood that all of that convoy was heading towards Leyte with supplies and troops, because we had hit that thirteenth ship with a previous torpedo that had been fired. There we were. We had fired all but two torpedoes. We had two torpedoes left in the forward tubes, numbers 23 and 24, and we were on the surface. Dick O'Kane had sunk 12 of the ships, had the 13th one up there in his periscope, and binoculars and the boys on the bridge. It was light enough that they could actually see the targets. It was a big troop transport. He estimated that there were about 5,000 Japanese troops aboard. Normally, as on previous patrols, we'd fire from 1,000, 1,200 or 1,400 yards. Picture yourself, there you were out there. You had this luscious target and two shells left.

You know, I'm a big game hunter out in Colorado and have been since the war, and I just quit big game hunting about three years ago. But I could see myself with one shell left in my gun, and there's a big bull elk trophy. I might even go so far as to lay the barrel of my gun across a tree limb to get a good shot. Dick O'Kane's strategy was to go in about 700 yards of that target, broadside, and he called for an 'all stop.' We talked about it in the prison camp afterwards, and I asked Dick about it. He said, "Well, Clay, yes, that's right. I did call for an all stop." Normally, when we would fire, be it submerged or surfaced, we would have two or three knots on the screws. We were not moving very quickly, but in slow motion.

Anyway, he called for an all-stop. He fired the twenty-third torpedo, and she went hot, straight, and heavy, and she did away with that target. I mean, there were 5,000 Japanese, and without a doubt, 4,000 of them didn't make it. He had two men on the bridge with binoculars verify the twenty-fourth torpedo went out of the tube. They followed the wake. It went out about 300 yards and he said it was like if you were going fishing and caught a fish on your line, and you were pulling the fish out of the water, and it was up dancing. He said, "That torpedo stood on its tail, dropped back into the water, and doing a hard left turned on itself." That was when he started pounding on the bridge, saying "Full speed ahead," pounding. If we had managed a knot or two, we would have made it, but of course, that is hindsight. That torpedo hit us after making that circular run. It came around on our port side. It hit us right at the maneuvering panel, which was located just before you stepped through the hatch into the after torpedo room. We would have had the length of the after torpedo room to have gotten out of its path, had we had any forward motion. But we did not.

Anyway, we had such good success. We sunk all those ships, and the crew was really starting to feel jubilant. We were told that after the fifth patrol we were going in for new construction, stateside. As a matter of fact, we had several members in the crew on that fifth

patrol who were part of the relief crew back at the sub base in Pearl Harbor. They knew that or had heard stories, and boy, they just busted their legs to get aboard the *Tang* because they knew that she was going to be going back.

One of the torpedo men up there said, when he padded that breach and the twenty-fourth torpedo was fired, "Let's head for Mare Island." He said no more than that and boom, that baby hit us. Picture this, if you will. There are so many people who aren't familiar with submarines, when I tell them this story, I say, "You know, you have to picture this." The *Tang* was an example. If you took it out of the water and put it in a football field, the bow would touch one goal post and the stern would touch the other goal post. You were looking at 300 feet. We were in 180 feet of water, so we hit ourselves in the stern and started to sink from the stern. Picture yourself at about a 45-degree angle with the stern resting on the bottom. We knew that the bow was out of the water because we could hear the waves splashing on the hull. There I was, sitting at the bow planes, and they were big planes. Today, operating bow planes is like driving a car. The bulkhead behind me was the portside bulkhead of the radio shack.

I was sitting on the bench in the front of the bow planes' steering wheel, and I didn't move four or five inches. I never got a scratch. I wasn't hurt at all, period. But picture this. Right there to the right of me, toward the forward part of the ship, there was the ladder that went up to the conning tower. You had the man on the Christmas tree. You had the diving officer standing right side of the chart desk, which was, on the *Tang*, in the center of the control room. We also had the gyro look at it just below the chart desk. I qualified and got my submarine dolphins on the second patrol on the *Tang*. That was when my training really came in handy. Picture this now. The torpedo hit us. We were sinking at the stern. The lighting all went out. We lost all hydraulic pressure. I immediately flipped the control for the battery-powered lighting. Because I had completed my training as a qualified submariner on second patrol, I was very familiar with

the fact that immediately above the chart desk in the control room, from the overhead, was the big lever that ran forward to aft. At the aft end of it, there was a pin. If you pulled that pin and let the lever swing down over the top of the chart desk, it opened all the vent valves for the forward part of the boat.

Whether you're aware of it or not, everything we were told and everything that worked hydraulically on a World War II submarine, could also be operated manually. There was a function and you could operate it manually. The chief of the boat was on the Christmas tree. He, the diving officer and the man on the hydraulic manifold that pumped water forward and aft for us were clear over on the starboard side. Those men, when that torpedo hit, were just literally thrown. The chief of the boat wasn't knocked out completely, but when I got the lights on, I got over to him I said, "Chief, let me help you." He knew who I was, but he was really stunned. He was the one who told me, "Clay, here we are now, at a 45-degree angle. We've got to get this boat leveled. There is no way we're going to get that forward torpedo room with this angle." That was the thing that prompted me to then crawl up on the chart desk, roll over on my back, throw my legs up around that lever on the overhead, pull the pin, and drop it down. Immediately, we started lowering. The boys up in the conning tower were thrown around also, but the normal way to come down from the conning tower to the control room was feet first.

Now, if you had seen guys come off a watch, they wouldn't touch a step. They'd come down and put their feet sideways, and just grab the handrails. They'd grab it and slide right down. You've seen firemen do that on fire drills. They can do that. We had two men come down, and they were the first two men to come down out of that conning tower. I was sitting right there. There was the ladder, coming down from the conning tower, and there was the deck right there. Two men came out of that hatch headfirst. They dove for that hatch, and they came down. The first man broke his neck. The other man who came down broke his back. They hit that steel deck,

coming straight down. They never touched a rung on the ladder or anything. They just dove through that hole.

The third man who came down was this little red headed lad. I'd have to look in the book to get his name again. This isn't Alzheimer's. I just can't remember his name. Most all the hatches on the *Tang* that opened upward were spring loaded, so that when you would undog and release it, it would itself go up. It had a lanyard on it, and at the bottom of the lanyard was a piece of wood about as long as my finger and as big around as my thumb. A lot of times you could just grab that lanyard and run the line through it. You'd just grab that and pull the hatch right on down, and then you'd dog it. This lad did that. He came down feet first, and he stepped on the ladder as he came down because he was in a hurry, believe me. He came down and just grabbed the line, and instead of coming down and getting hold of the wood, he just grabbed the line itself. When he grabbed that piece of wood at the end of that line it and pulled the hatch to dog it, it got caught up on the gasket where the hatch came down. Even though he got it down and he got it dogged, we had a stream of water about the size of my wrist coming into the control room. That was the time that I went over and helped the chief. The stern planesman, whose name I can't remember right now, got up and helped the boys who were injured.

We had a man with a broken neck and we had a man with a broken back. We had a man sitting on the helm. We had a helmsman in the control room also. Now, he wasn't doing anything. He was just there in case they wanted to switch from the conning tower down to the control room. He had a broken arm. I opened the vent valves and started to level the boat to take her on down. Unbeknownst to me, during all the firing and everything, just prior to the torpedo hitting us, my buddy, George Zofkin, to whom I turned the throttles over when I went forward to the control room when called to battle stations submerged, turned the throttles over to his oiler. George told me that what happened with him. His oiler was a well-trained lad. Hey, we had sunk

ships. We were going to be out of torpedoes. We were going to be headed home. George went up to the galley for a cup of coffee.

He was standing right at the galley. You stepped through and there was the radio shack and then the control room. He said, "I was standing right there, Clay, when the torpedo hit. The passageway there is fairly shallow. It shook me around a little bit, but I just stepped through and pulled the hatch closed." That closed off from the control room aft. You had the after battery compartment closed off from the control room. I was gone and didn't know that had happened, but later on, I'll tell you a little bit about what happened in that after battery room. Unbeknownst to me, George Zofkin, my buddy with whom I had left my family back in San Francisco, was among the survivors in the control room. I didn't know that until we got up in the forward torpedo room.

By that time, I was getting the chief up and helping him. He was bleeding from his head a little bit and so forth, but he was conscious and knew what he was doing. He said, "Okay, let's all move forward now," knowing that we were going to have to help those boys. We had to carry the boys with the broken back and the broken neck. We had to carry them forward. We went through the officers' quarters and the forward battery compartment. In the wardroom was Ensign Ennis, who was an ensign when we put the boat into commission. I said earlier that he was still an ensign on the fifth patrol, and I figured out that the reason for that was because he had taken a steel waste paper basket. Hey, you know, he was smart. He got all the codebooks. He knew where to go to get the books and everything, and he was folding them up, taking pieces of paper and folding them up a little bit. Then, he touched a match to them. God, he was going to burn them! By that time, Ballinger and I were coming through and saw Ennis do this. We stopped him and said, "Let's not do that." You are all familiar with it. The opening in the wardroom going down to the forward battery compartment was a good size. Of course, there was that opening in

the top of those batteries, and you know what was in there. It was sulfuric acid. If you took a piece of paper, wadded it up like that and put it in there, zoom, it was gone. That sulfuric acid would do a number on it right, so that was what we did. We got all the codebooks, opened up those batteries, and put them right down in that sulfuric acid. We figured if the Japanese ever got to the sub, they wouldn't get the codebooks. We got that done and we moved on forward.

Ennis was on up forward then, and so was another officer. He was Lieutenant J.G. Hank Flannigan, a torpedo officer. As of then, nobody had even started to get groups of four together. In my talk the other day, I mentioned a couple of asinine things that happened. Well, one of those things was Ennis trying to start a fire. That was the last thing we needed. We did not need to burn off our oxygen with a fire. When Ballinger and I got up in the torpedo room, right away the chief said, "Hey, I'm going on this way." Just as he and I got up there, there was a group of guys standing right below the hatch and they were talking. He was a chief Torpedoman, and the other guy was a First Class Motor Machinist Mate, and his name was McMeryl, but I can't think of the name of the Chief Torpedoman right now.

Anyway, Chief Ballinger and I didn't see it, but were told about it. Both McMeryl and the Chief Torpedoman crawled up in the escape chamber, closed the hatch and flooded it down. If you remember, that was how you knew whether that hatch up in the escape chamber was open. There was a lever in the forward torpedo room that, when the hatch opened out to sea, came down. It automatically came down. In other words, it worked like this. The hatch opened, the lever came down, the lever came up, and the hatch closed. That was the way you closed the hatch after the four people escaped. You closed it, pushed it back up and closed that hatch. Then, you drained the water down, let it just go down into the bilges, opened up the hatch, went back up and got four more men up there. Those two dudes got up in there. That was the other asinine thing that happened. Those two dudes got up in there and they never let the buoy out, fortunately

for us. I thought about it many times afterward. It was fortunate for us because we used that buoy and that line. I did, anyway, and they were gone. I'm not sure it is even questionable that, if they went out that way, they would have hit that opening in the deck. Anyway, they were gone. We got the story. Somebody was telling Ballinger about what happened and Ballinger said right away, "Clay, you want to go with me? I'm going to be in the first group." I said, "You bet. I'm going."

That was when I first discovered that George was up there. He rolled over to the side of me. There was George Zofkin. I said, "Hey, George, where did you come from?" He told me then about being there at the galley when the torpedo hit, and he just stepped through. We got the new Momsen lungs out and opened the cellophane. They were in the cellophane pack. I put one on and got the mouthpiece and the nose clamp. George reached down and took the wire clip that was on the rubber exhaust valve. He took that clip off for me and saved my life. I would not have taken that clip off. I was told that later on, when we were in prison camp and after we were out of prison camp. Back at sub school, they once brought a brand new lung into class, because when we'd go through the escape chamber at sub school they had just a rack down there. You'd just grab a lung off the rack, one that somebody may have used just two hours before. It didn't make any difference. You could use it over and over.

Anyway, we had the brand new lungs. Why in the world did they ever have that thing? It was flat rubber. It was like when you were a kid, took a raspberry and made it so that water couldn't get it but air could get out. That was the principal of the thing, because the lung wanted to keep getting big like that. Even when we'd use it on the escape chamber, there were air bubbles constantly coming up from it.

Anyway, George reached down and took that off me. Right away, I grabbed another one and I said to him, "Come on. Let's get this on." Remember that he was my buddy with whom I

left my family back in San Francisco. George said to me, "Clay, I have a confession to make."

"God," I thought, "George, why are we talking about confessions? Let's get out of here. What are you talking about, a confession?" He said, "I can't swim." I thought, "Oh gee."

Since then, I've thought about it. I think about when we'd go on rest and relaxation between patrols. We'd go to the Royal Hawaiian Hotel. George and I had roomed together. We'd go out on Waikiki Beach and frolic and everything. I have pictures of us in our swimming trunks and so forth, but George never did ever go in the water. I had never even thought about that before then.

I told him, "George, look, you and I both know if you close that valve properly on that mouthpiece, that thing acts just like a Mae West life preserver. Let's worry about that after we get gone." He said, "Clay, do this. You go with this first wave of four, and I'll come up with the next wave." I thought, "Well, that's fair enough." Ballinger was there and ready to go.

You've seen the escape chamber. It was really 'togetherness.' You had four men standing in there and were allowed maybe a 12-inch step to step out. Remember that when you stepped out, it faced and opened aft. You were looking at the aft of the ship. When you stepped out, you were on top of the pressure hole. You were standing on top of the pressure hole of the submarine. The height of it was about shoulder high. Believe me, Ballinger knew every step that we needed to take. There was no panic. The four of us had our Momsen lungs. You had, in the escape chamber, a gauge giving you the outside pressure of the water.

Fortunately, we didn't have any harm done to our air supply. We had air, which was a very important factor, as you all remember, because on your lung, you initially charge it with an air hose just like you'd fill a bicycle tire. That was the initial charge, and Ballinger was standing next to a lad who's name I can't remember, but who was immediately across from me. There was the hatch, and it opened that way, and I was standing next to it. Ballinger was that way from

me, and the other chap was on my left shoulder. Immediately behind Ballinger was the reel with the buoy and a line attached to it. As I remember, it was about the size of a soccer ball, but maybe not as large as a basketball. It had a lanyard around it that was stapled ever so far so that you could get a handhold on it. Ballinger said to me, "Now, we all have our lungs on." We flooded down with water up to our shoulders. Ballinger opened the air pressure five pounds to exceed the sea pressure. "Now," he said, "Clay, put your mouthpiece in and your nose clamp on and just duck down in the water and try it once in your mouthpiece." I did. I said, "It works well, chief. It works okay." He said, "Okay, good. You're ready. Now, we're going to open the hatch." We did that. I tell people that it was the same situation as the escape chamber. Water did want to come in a little bit. It was a little scary. You opened that hatch and the door swung pretty freely, but the water did want to come in a little bit. It rose up to our chins and settled right back down.

Then, he handed me the buoy and said, "Now, Clay, when you let the buoy out, do this. It's simple mathematics. Count each knot." I did. I was letting the buoy out, and it wanted to go right to the surface. It went right out and straight up and I was counting the knots. I knew when that buoy hit the surface because the line was jumping in my hand. It was riding on the waves. I told him that and he said, "Okay, hold it."

By the way, we had battery lighting in the escape chamber. Outside, it was totally pitch dark black. He said to me, "Clay, let me hold the line." We were loaded. I've forgotten where the Gunner's Mate kept the gun, but whenever you went on topside watch, you'd go and get a .45 from the Gunner's Mate. I've forgotten where the locker was that he kept the .45s in, but he brought some up there.

We knew that we were in shark-infested water. We all had .45s. We each had a shark knife. We tied our pant legs down there because we had sea rations stuck down in our pant legs. Ballinger said, "Now, count the knots," and I did, and it came out right on the nose at 180 feet,

and that was what the gage was reading. Bill just said to me, “Clay, go ahead, put your mouthpiece in and go for it.” He wanted me to cut the line. He said, “Clay, let me hold the line. You reach back over here and cut the line from the spool, but leave enough loose so that you then can take the loose end while I’m still holding the line.”

We were down at the bottom of the ocean and the hatch was open. We had three ladder steps on that escape chamber out there. It was a piece of welded steel not as big around as my thumb. But there were steps, and you came out and get hold of one if you were going to go up. On the *Tang*, the opening in the deck was three feet square, the size of a yardstick. That was the opening immediately above the escape chamber. He said, “Tie that out there for us, Clay.” I don’t know whether I tied a square knot or not, but I can remember I tied about three knots in it. I didn’t want it to get away from us, you know. But I was just reaching out here. I was still inside the chamber and just reaching out there and tying the knots on it. I put my mouthpiece in, my nose clamp on, and proceeded on out myself. I grabbed the line and I followed the line up. It was totally dark. By that time, it was probably six or six-thirty in the morning. It was definitely daylight, because as I started getting toward the surface, I could see the water getting lighter and lighter and lighter.

As I broke out of the surface, my head popped out and immediately I said, “Oh boy. I made it.” Remember that the nose clamp was strictly to keep you from breathing through your nose. I reached up to take my nose clamp off and as I did, I could see that I was bloody. There was the buoy and I was holding on with one hand, and I reached up with my other hand and saw that I was all bloody. I spit that mouthpiece out like that and asked, “Why am I bleeding? I didn’t strike anything coming up. I didn’t get the bends.” But when I was interrogated, after I got out of the prison camp, this lad told me, “Mr. Decker, what happened was probably this. It’s almost like you go to a high altitude. You get a nosebleed or something. You have little superficial blood

vessels in your cheeks. If you came up rapidly enough, they burst, because the bleeding stopped almost immediately.” There was no pain. There was no aching sensation or anything. But the asinine thing that I did was spit that mouthpiece out before I reached down there and turned that valve off. Had I done that before I took the mouthpiece out, it would have acted as the Mae West life preserver. Well, I goofed. The interrogating officer asked, “Well, did you panic, then?” I said, “No. I would not say I panicked. I just didn’t know why I was bleeding. Forget that.”

At about that time, when I was through with all of that, and I hadn't taken the lung off yet, Ballinger came to the surface. He was over from me just a little bit more than arms reach. I could have held on and reached with both arms stretched and grabbed Ballinger. That was what that interrogating officer told me. He was a Navy man, too, but I can't remember names or his rank. I said, “You know, something told me, ‘don't do it.’” Ballinger was drowning. The man was there. His face was bleeding. I could see. He was bloody. He didn’t have his mouthpiece in. He didn’t have his nose clamp on. He was screaming, and water was coming out of his mouth. The man was drowning. The interrogating officer told me, “It's a known fact that a drowning man can pull a horse under the water. If he had have touched any part of you, you would have been with him. You wouldn't be here talking to me today. He was grasping. The man was dying. He was grasping for straws. If he had grabbed you, you would have been down with him.”

Anyway, like I said, something told me not to do it. He was screaming. He was right there, and I did not reach out and grab him. The two bodies of the other two boys never did come to the surface. The only conclusion we could come to, when trying to theorize, was that those two boys, no doubt, when they came out of that hatch, did not get a hold of the line. Remember that it was pitch dark. We were down at the bottom of the ocean there. Picture that. If you were down there, had your lung on and your mouthpiece in but stepped out of the chamber and varied just a little bit, you were going to miss that yard stick square opening in the deck. That was what

we called the 'super structure area.' They wouldn't have known whether to turn right or left or what. Their bodies, no doubt, hung underneath that deck. They certainly panicked and then drowned. It was interesting because in the next wave of four, only one man made it. No other bodies surfaced. There were five waves of fours, and only one man made it out of each wave of those waves. There were five of us up on the surface around this buoy. The sixth man finally showed up. He was a First Class and his name was Larson. He wasn't in as bad a shape as Ballinger appeared to be, but the man was drowning. He wasn't bleeding, but he was spitting water and so on and so forth. Had we had him on a beach, we could have taken Larson and pumped him dry, no question about it. As a matter of fact, we were in the water between four and five hours before we were picked up, the five of us hanging around that buoy. We took turns hanging on to the buoy with one hand and swimming with the other. We took turns holding Larson up because he couldn't do it for himself. He couldn't swim for himself but was still alive. The man was still alive. Two of the youngest lads were named Truckey and Norwanski. Both of them were Torpedomen and both had just come onto the *Tang* for that fifth patrol. They came out of the relief crew. They were the ones who said, "Hey, we're going to go back to the States with this baby."

Anyway, those two young guys told the rest of us that we were right straight off of Fuchow, China. By that time, it was light enough that we could look over and see the Chinese coast. In the morning, the tide was coming out. You've heard the old lesson that you can't swim against the tide. Believe me, you can't swim against the tide. Those two young lads were both young, husky lads. They said, "We're going to try it." They threw their lungs off and started out. They didn't get twenty yards. They were back with us at the buoy. There was no way you could swim against that tide.

If it had been afternoon and the tide had been going in, maybe those two boys could have made it. Besides, they were loaded like the rest of us. We were in the water between four and five hours before the Japanese picked us up. But in the meantime, we all unbuckled our .45's and let them go. We dropped our shark knives, shoes and everything we had. We were down to just our skivvies. That was all we had on when we were picked up. In the meantime, we were holding Larson. We were keeping him up, and a Japanese destroyer escort dropped anchor about 1,000 yards from us. We could see it in the open sea there. It was broad daylight. We could see the Japanese destroyer escort.

They dropped a whaleboat, a rowboat with two men. They were armed. They rode over to us. We all crawled in that rowboat. We got Larson in. One of the Japanese had his gun on us. We were sitting in the back of the boat. He was telling us to sit down and so forth in Japanese, but he was motioning. We could tell what he wanted. The other guy was up in front, in the bow, trying to get the buoy in the boat. He finally gave up. He couldn't get it on. We didn't tell him it was tied to a submarine.

Anyway, they rowed us back to the boat, and they had a rope ladder down the side of the ship. I was the last one out of the whaleboat to go up that rope ladder. I looked back over my shoulder, and those two guys were dumping Larson's body over the side. They didn't even try to give him any artificial respiration, they just dumped his body over the side. Picture it. It was a hot day. The sun was shining. We were on a steel deck in our skivvies. We had not been exposed to any sunlight for a long time. We were surprised, right away, to notice that the skipper and three other men had been picked up in the water. That made a total of nine of us. That was probably the roughest treatment we received the entire time we were prisoners of war. I'll tell you, we decided and theorized, but that ship probably picked up a good number of the survivors from the ships we had sunk.

Now, picture yourself on one of those ships, down in the boiler room, when that torpedo hit. With that hot steam, some of those guys were like lobsters. They were scalded, almost to death, you know. Well, Jesus, they looked at us and said, “Here are the poopers that did this to us.” They'd grab us by the hair and take a live cigarette butt and stick it up our noses. We spent five days and nights on that hot steel deck with no water and no food. Oh, the Japanese word for restroom is ‘binjo.’ They took us to the binjo whenever we had to go relieve ourselves and brought us back and sat us on that hot steel deck. Believe me, by then, we were all blistered. Our lips were blistered. Every one of us confessed to each other that, when we got in the prison camp, we all even tried drinking our own urine.

After those five days, they pulled into Taipai. They tied up there and put black hoods over our heads, tied our hands behind us, and tied us one to another in a line. They marched us, probably in the streets there, down the main street. We couldn't see, but we could hear and feel little old ladies and little kids coming up and hitting us with sticks and so forth. We had to carry a sign. It probably read, and we theorized about this, “Here's an example of your ‘superior race’” or something, because little kids and old ladies were hitting us with sticks and so forth. Well, they took us to an army post just outside of Taipai, in the main town there. I don't know if you've experienced any Japanese military personnel or not, but an officer in the Japanese army was a good example. If he was talking to a subordinate, you could be two feet away, and instead of using a tone of voice like the one I'm using right now, he screamed. He screamed an order to the man. They did take the black hoods off our heads, and we were standing in line. They were screaming these orders back and forth to each other. We thought, “Uh-oh, this is it. This is the firing squad. There's no question about it, because these guys are standing here with rifles.” There were army personnel members standing with rifles. We thought, “This has got to be the firing squad, no question about it.” They were screaming, but that was just their nature. We

found that out later. An officer gave an order to his subordinate. He could be standing right there. He screamed it to him. He didn't just give it to him a little tone of voice.

They threw us in a potato cellar that night and did give us some polished rice. Whether you're aware of it or not, when you polish rice, you do away with a lot of the nutrients. They loved their polished rice. Well, they fed us. Here in the States, we call it 'meal,' or 'chicken feed.' It grows on a stalk similar to a corn stalk. The shape of their heads was like little pellets. Actually, that had more food value to it than polished rice. Our only problem was that we'd never get enough of it.

Anyway, we did get a little ball of food that night, and the next day they put us on a train and sent us clear to the north end of the island to get us prepared to go on a boat ride to the mainland of Japan. They put us down in the hold on a ship loaded with sacks of sugar in a rough sea. We were down in the hold clear up to the bow. We all got so seasick that you wouldn't believe it. We said our prayers. We said, "Jesus, I hope our submarine Navy is not on the ball and does not sink this baby before we get to Japan," because that did happen to Japanese ships. We made it. They landed at Yokohama. It was nightfall when we got into Yokohama. They put us on one of those fast trains. There we were, still in our shorts, and it was cold weather. As a matter of fact, when we got to the station, the first camp we were in was Ofona. It was inland from Yokohama, right at the foot of Mt. Fuji.

When we got off the train that night, it was raining. We were walking in the rain for about two hours before we got to Ofona. Ofona was an interrogation camp. We were interrogated and put one man to a cell, isolated in a solitary confinement sort of thing. The Japanese navy, army and civil defense interrogated us. You name it, and they interrogated us. As a matter of fact, it was interesting. One of those interrogators we finally nicknamed 'Handsome Harry.' He

would show up every once in a while in a tie, white shirt and suit. If you closed your eyes, you wouldn't know that you were talking to an Oriental. He spoke perfect English.

As a matter of fact, the first time he interviewed me, Handsome Harry said, "Mr. Decker, where did you join the Navy?" I said, "Denver, Colorado." "Oh," he said, "Then you're familiar with the Brown Palace Hotel in Denver?" "Oh yeah," I said, "Very much so." He said, "Mr. Decker, I lived in the Brown Palace Hotel for two years while attending Denver University." I thought, "You think those poopers weren't planning Pearl Harbor a long time before it came to pass?"

Anyway, one of the things that Dick O'Kane immediately told all of us was, "Guys, don't take any undue, unnecessary punishment, okay?" The other officers were Larry Savatkin and Hank Flannigan. Larry Savatkin was a lieutenant, and Hank Flannigan was a lieutenant J.G. torpedo officer. There were three of them. The rest of us were enlisted men. If you got caught stealing or lying, it was definitely cause for a beating. He said, "Don't take any undue punishment because you guys don't know anything that they don't already know. I'm the guy they're after, so don't do it." My God, Dick took some awful beatings.

Anyway, to prove that point, and I mentioned it when I talked the other day, one of the guys who interviewed me questioned me about Fairbanks Morse diesel engines. I went by what Dick had told us, and, you know, he was our skipper. We got through with our interview and the interrogator brought in a catalog, a book out that was published with the engine at the factory where it was made. God, he could have caught me in a lie just like that, so Dick gave good advice. There was an officer and a gentleman. I mean, that man graduated from this institute here in 1934 and went out to do his job, and he did it well. Like I said, he absolutely showed his colors with his men there.

I think I mentioned to you guys that he told all of us who were not of officer status in the prison camp, “If any of you guys who want to make the Navy a career, follow me when we get out of the prison camp. When we get back to the States, if you want to stay in the Navy, I guarantee you, you'll go wherever I go, and I'll guarantee you that you're going to raise a rate a year until you become an officer. Then, you're on your own.” Two of the guys took him up on it. The Boatswain Mate was my friend, Bill Liabold . Bless his heart. Bill and his wife, Grace, live on Palamar Mountain outside of Escondido, California. Even today, we have a great rapport. The other guy who took O’Kane up on the offer was Floyd Caverly. He was a First Class Radar Technician. Savatkin and Flannigan were also career Navy men.

However, of the nine of us who did survive, in the sequence of events when we got back to the States, Hank Flannigan was the first man that passed away. Truckey, one of the younger lads, was the next one that passed away. This is almost unbelievable, but Skipper O’Kane passed away on a Sunday in 1994, in Santa Rosa, California, in a nursing home with Alzheimer's disease. Pete Norwanski, who was one of the torpedomen who came aboard the *Tang* on the last patrol, in Baltimore, passed away that same Sunday evening. That boils it down now to only four of us still living, out of the nine. No, excuse me. another has passed away, and he was one of the five who came up from the bottom. He just passed away a year and a half ago in Los Angeles, California. He was a young chap.

Oh, one of the prisoners there when we got there was the ace Marine pilot, Pappy Boyington. Pappy had been shot down about a year before we were captured. He was working in the galley in that first camp. How he got thrown in with the *Tang* group, I don't know, but he did. The Japanese never allowed us to be POWs, or prisoners of war. They contended that on the freighter we sank, about ninety percent of the cargo was munitions. They also contended that 95 percent of the crew was civilian. Therefore, we were at war against their civilian population and

weren't entitled to be POWs. The consequence of that was that we only got half the food rations. The second camp we were sent to had 600 prisoners. We weren't entitled to mingle, fraternize or speak to them or anything. We were kept segregated.

INTERVIEWER: Was that near Yokohama?

MR. DECKER: No. The second camp was on an island in Tokyo Bay called Omari. It had a wooden causeway leading out to it and was just on the outskirts of Tokyo. But like I said, we weren't allowed to speak or fraternize with them. That was the other consequence. We only got half the food rations that the other prisoners got. The other thing involved me, and, of course, Skipper O'Kane. They never notified the Red Cross or our government that we were captured. In my particular case, after I got out of that prison camp, my wife was remarried. Mrs. O'Kane waited for Dick. Anyway, that happened to me, and it happened to Pete Norwanski. He was another one who was married. His wife had also remarried.

We spent our time through the winter months at Ofona. A lot of people don't realize it, but Japan can get a good foot of snow on the ground and zero degree weather. The cells that we had at Ofona were solitary confinements. We were issued three blankets that were the same as our Army blankets, but there was no heat in any of the buildings. As a matter of fact, in that interrogation camp, we never minded being interrogated that much, because when an interrogating officer would come, they had a room set up for it. The Japanese weren't sitting in chairs like we were. They sat on the floor, and what would be your coffee table at home was their main table. The interrogating officer came and put a blanket over that table, and they put a hibachi underneath. From your butt down, you know, it was nice and warm. I would say, "Let's just keep talking. Ask me all the questions you want." We were down there and had warm weather. In the cells, the way we kept from freezing to death was by learning how to take those blankets and wrap them around ourselves. Most of the time that we slept in the winter, we did so

sitting up. You started at your feet and ankles and came clear up, just as though you were a mummy and got right back in the corner. You'd get in a sitting position and could keep from freezing to death.

That was a kind of a tough one. We had allies of ours in that camp. There were some Dutch, British and Royal Navy guys. Back in the days, and maybe they still use it today, but when I was in the Navy, we called the English 'limeys.' Now, they were our allies and they were in this thing with us, but that was just what we called them. Anyway, we had some limeys in that camp. It was interesting in Ofona, in that camp. We had limeys there, too. There was Boyington, our ace Marine pilot. He shot down 28. We'd just go up, pat him on the arm, wanting to touch him, you know. "God, here was a hero," we thought.

Well, let me tell you something. If you stole, what you did steal was food. Anytime you could steal some food, you did. Believe me, guys, I think the worst thing a person can die from is starvation. Anyway, Boyington got caught and had to take a beating. What the Japanese did was line us up out in the compound, Americans and limeys and all. There was a foot of snow on the ground. We were lined up out there. By the way, by that time, we did have some kind of clothing. It didn't amount to much, but we had some clothing, and they allowed us to take one blanket, wrap it around ourselves, and stand at attention while a Japanese soldier beat him. They stripped him to the waist. They'd tie your hands and put them over a hook on a pole, and this guy started beating you until the blood and everything else was running down your back. When this guy got through beating Boyington, and he was practically in Boyington's face, he cut him down. Boyington was standing at attention, and the guy was saying, "Do you understand why I just beat you?" We were all standing at attention, watching this go on. Everybody was just as sober on their faces as they could be. Boyington was standing there, at attention, and he said, "Go screw yourself, little man." I have to tell you something. From that point forward, those limeys had a

number one respect for Pappy Boyington. He didn't have to shoot down 28 planes. When he said that, nobody broke rank or changed expression on their faces, you know.

Of course, the Japanese didn't know English. There he was, standing there in the snow with blood running off his back. He was a heck of a man, a heck of a guy. They took us down to Omari about the last week of February of 1945, and in the barracks there, my cellmate was Pappy Boyington. I could tell you a lot of stories about that. Over there, we'd always call Pappy 'Pappy,' but for the most part, you called everybody by their last name. The way the Japanese work it, the names are reversed. In other words, instead of 'Mr. Weir' you'd be 'Mr. Gary' I was called 'Deckersan,' and Pappy was 'Boyingtonsan,' and so forth. Pappy always called me Deck, which was short for Decker. Do you know something else? Whether you realized it or not, and it was probably because of the Geneva Convention or whatever, all the officers got paid every month in yen. They had no place to spend it. They'd come to our cell once a month and pay Pappy. He probably had enough yen to buy half of Tokyo.

Every morning at the second camp, they would take crews of men out and send them either to the shipyards or the steel mills to work all day, and they'd be back in the late evenings or late afternoons. The only ones who would remain behind were officers. Officers didn't have to go on work details. Boyington finally convinced them to let us do something, just to get out of the barracks. Whether you're aware of it or not, he used to tell me about that Corsair flyer that he flew. "Deck," he said, "the government never built that baby right." He would moan about it. His buttocks and the back of his calves of his legs, when he was shot down, were not loaded, but he had several pieces of shrapnel in him. We got no medical attention whatsoever. But you can take a piece of green bamboo and a piece of glass and sharpen that bamboo so that it is as sharp as a razor. Well, we'd sit out in the compound in the sunlight and he would work a piece of that shrapnel out of the calf of his leg. He'd reach down and hold it. There would be puss and

everything. He gave me this really sharp piece of bamboo, had me just cut it open, dig the shrapnel out, let it bleed there, and then he'd just hold it in the sun light. How he ever kept from getting gangrene, I'll never know.

They finally wound up taking us out while our B-29s were overhead. We were close enough to Tokyo there and whether you know it or not, practically every house in Tokyo was made out of bamboo. The B-29s would come over and drop one incendiary bomb that would wipe out six blocks. Those bamboo houses would just go up like fire paper, you know.

Anyway, we were finally taken out on work detail and the B-29s would bomb out an area. They'd march us out to that area, and back in those days, all of their vehicles were charcoal burners, you know. They burned charcoal, but they'd capture the gas and run it through the carburetor and then run the engine. We went into the bombed out areas, and we'd load the dead bodies on a flat bed. I don't know if you've ever loaded a dead, burnt body, but when you grabbed the skin, it was sticky. God, it wanted to come off on your hands and so forth. We didn't have any gloves or anything, but we had to load the dead bodies and get them out of the way. Then, we'd gather the rest of the debris that was around, put it in piles, like bonfires, and burn it, and then they let us till the soil and plant a garden. It was just something to do. That was the main thing.

But Boyington had a nicotine fit that wouldn't quit. He'd get caught smoking every now and then and he'd take a beating for it. When we'd be marching to those areas, he was constantly looking down at the ground. He'd find Japanese cigarette butts, and by about the time we'd get back to camp that night, he'd have a handful in his pocket.

The next day, if we didn't go out, we were there in our cells. We had an opening about, oh, 12 to maybe 14 inches square in the cell, just right so that during the day, the sunlight would

be coming down through the opening. Do you remember the flashlights from years ago, Gary?

Did they have convex lenses?

INTERVIEWER: Oh, yes.

MR. DECKER: The flashlights today only have pieces of glass for lenses. You could take that convex lens and start a fire with it. Well, Pappy would take this tobacco, and he'd roll it in yen. He'd get about five of them and have me hold the lens. You got up there like that and he'd get one going. Well, Gary, he'd have to smoke all five because the sun would change and I couldn't light another one. He'd just chain smoke all of them. God, what a character he was.

INTERVIEWER: Was the second camp that you were in the last of the camps? You stayed in Tokyo until the war ended?

MR. DECKER: Yes.

INTERVIEWER: What was liberation like? How did you get out?

MR. DECKER: Oh boy, Gary, I'm so sorry. I brought pictures and I have them in my suitcase at the hotel. I sure would like you have one, you guys. I've got a picture that was taken of me when that Russian submarine went down. God, the media came to the house, you know. They got me in limousines and took me to radio stations and everything else. But I've got a picture of me the day I was liberated. By the way, in the Navy Yard Museum in Washington, you can see it. Oh, it's a picture four feet wide and five feet high of us being liberated out of Omari and holding the flag there, the American flag. There's a guy right in the front row with his hand up like that. That's me, and that's in the Navy Yard. I've got a book. Let's see. What do they call it? Oh, it's called 'VJ day.' I've got a fifty-year anniversary book. It's a hardback and it's got that picture right on the front cover of it. That's me.

INTERVIEWER: It's a very famous picture.

MR. DECKER: My first wife and I were talking about the tattoos. There I was, naked. I had just a pair of shorts on. It was an island, you know. It was in Tokyo Bay. Bull Halsey came into Tokyo Bay with the fifth fleet, and he had the hospital ship, the USS *Benevolence*. When that picture was taken, we had already been liberated. The Japanese pulled out about a week before. They pulled out and all they left were four guards at the main gate. We had a general, a one star general from Australia. Military-wise, it was the chain of command, but everybody voted for Boyington to be the top dog when we go to take over the camp. You know his boys of Baa Baa Black Sheep. They didn't realize that he was still alive. We got up on the roof and painted 'Pappy is here.' Oh, Jesus, the Black Sheep squadron went bananas, you know. 'Bull Halsey' came in, and he came to the island with Higgins landing boats and picked us up. That's where that picture was taken.

In the interim, or while we were in the prison camp, the B-29 was developed. We didn't know anything about it. It was interesting. The Japanese used their own numerals, as far as numbers went. One of the first things they taught us to speak in Japanese was numbers one to ten. They used 'A,' 'B' and 'C.' B-29s would fly over and they'd all run into the shelter and leave us up topside.

INTERVIEWER: They rode the Higgins boats in to pick you up?

MR. DECKER: Oh, yes. Bull Halsey then, like I said, was there with the fifth fleet. On the very day that picture was taken it was on the front page of the *Bulletin* in San Francisco. My first wife was working there, and she saw that picture. She went down to the *Bulletin*'s office and asked them, "Could you possibly pull the glossy, the actual picture?" They blew it up, and there were Clayton Decker's tattoos on both arms. I have big newspaper articles all about it, too. By then, my son was pushing four years old. In the pictures, he's sitting right there by his mom, and she's

looking at that newspaper, and sure enough, there are my tattoos, right in the front of that picture.

I've got that picture, and I'll see to it that before we leave, you guys get a copy of it.

INTERVIEWER: We'll get it from the Navy photo collection. That was a nice flag in that picture. Did one of the prisoners embroider that flag?

MR. DECKER: Yes. That was 'Slim' who did that. Slim has since passed away. He had the American flag. There was the Dutch flag, also. Slim Landron was a sailor off of the USS *Grenadier*. The *Grenadier* went down. They scuttled her and the whole crew was captured. There were some of those boys in that same camp. Why they mingled and did things, and the guards isolated the *Tang* guys and didn't let us become POWs, I'll never know. I've never found out.

INTERVIEWER: Maybe the *Grenadier* didn't take out 13 ships in one shot.

MR. DECKER: Yes.

INTERVIEWER: How did they ship you out, on the hospital ship?

MR. DECKER: That's interesting, too. Don't misunderstand me. I don't know that much about aircraft, but I'm told there was about a five-day interim before the Higgins boats came and picked us up. Hey, we broke into one warehouse in that camp. There were 10,000 Red Cross packages. Those jerks never issued them to us. The B-29s had come over and that was the first time we had ever seen them. If you took a B-29 and tried to fly it low and slow, Gary, they were doing it like this. They were dropping foodstuffs to us in 55-gallon drums on parachutes, trying to hit the beach. The Japanese pulled out, but they left, at the main gate, four guards. Two of them faced one way and two had their backs there. They sat there with their guns and just a lean-to shed. A 55-gallon drum of peaches came right through the roof of that shed and killed all four of them. It surely did. Our planes dropped a peach bomb down and killed them.

I was on the very first flight and among the first 21 prisoners of war of Japan to return back to the United States. I was on a C-54 with no seats. It had benches down the side, and it contained only officers. I was the only enlisted man, so I asked Pappy, "Did you get me on this flight?" He replied, "Deck, I didn't have anything to do with it." Well, I know he did have something to do with it. I was on the first flight of 21 prisoners of Japan and the pictures I have in my scrapbook at home and everything that was taken when I landed. We landed in Guam, refueled, and went through a chow line. The next stop was Hickam Field, Pearl Harbor. They took us to the hospital, issued us a complete C-bag of Marine clothes, and after one night we took another flight into the naval station in Oakland, California. They checked us into the naval hospital there.

Dick O'Kane was in bad shape, physically. I mean, I doubted that Dick would have lasted another two or three months had we not been liberated. He was in bad shape health-wise. Most of us had what they called 'dry rot.' What happened was that you took your hand and pushed it on your skin and it would stay indented for a while because the lack of citrus food, vitamins, and that sort of thing. They immediately started treating us for that. I didn't get my discharge right then. I got a ninety-day liberty leave. I went home to Colorado and went big game hunting. I then went back and got my discharge.

In the interim, I found out that my wife had remarried. Of course, the only thing to do then was to go through the divorce procedure, which we did. The only thing for which I asked, and was granted to me, was the boy. By the way, that lad, in June of this year, will be 60 years old.

INTERVIEWER: There you go.

MR. DECKER: He lives in Page, Arizona.

INTERVIEWER: When you got out of the service, what sort of occupation did you take up?

MR. DECKER: I got out of the service and had some friends, two brothers who were born and raised in my little hometown of Peonia. They were in the gasoline business in Denver with the Sculley Oil Company. They were Sculley Oil Company jobbers, and they got me a job there. I was with Sculley for about 15 years, and I was the district retail sales manager in Denver. At one time, I had 62 service stations. I had five city salesmen, of course. I told my wife, "I'm going out and showing these guys how to make money, and I'm sitting on a lousy salary. I've got to get into business of some kind." Gary, I bought a trash business. I started with one truck. I drove it. I got a second truck, a dump truck, and I hired a driver for it. When I sold it 25 years later, I had 14 trucks, and 10 routes. That was kind of my civilian life then.

INTERVIEWER: That's not bad.

MR. DECKER: I turned 80 in December, last year, and my wife, bless her heart, January of this year, she turned 84. We have 'motor homed' all of our lives since. It's not everybody's bag, but it has been ours. As a matter of fact, the motor home we have now is a little mini-Winnebago, class C, and it's number six. We had five previous ones. As a matter of fact, when we get back to Denver from this trip here, we're going to get in the motor home and go to Loflin, Nevada, to a southwest regional World War II submarine veterans gathering. We're trying to keep pumping away.

I have this oxygen thing that I'm on, Gary. A little over a year ago, the VA went into this right lung of mine, and after they came out, they said that I had a nodule in there. Everything was benign. But the first thing they asked me was, "Clay, have you ever been in a bad automobile accident?" I said, "No, I never have." They said, "the only conclusion we can come to is that your right lung is a mass of scar tissue."

INTERVIEWER: Oh.

MR. DECKER: The only conclusion we can come to is that it happened because the Japanese would beat us. They just stripped us to our waists, tied our hands, put them up over a hook, and that right lung probably took more beatings than it could handle. Of course, during my younger years, one lung was good enough, I guess, for me to get along with, but it just showed up recently. The main reason I have to be on oxygen is that my lungs aren't producing enough oxygen to get into my blood stream. If you don't have enough oxygen in your blood to get to your brain, you're finished business.

It's interesting. You remember me using the Momsen lung. One of the things that instructors would tell you was that the biggest factor in using a lung back when we were trained was that no two individuals had physical setups that were completely alike. In other words, my physical set-up and my body are absolutely different than yours. You, Gary, as an example, may be able to actually breathe free oxygen. You may be able to breathe free oxygen longer than I can, or vice versa, you know. That was the thing that used to bother us. In the 100-foot tower, when we were down 180 feet, you said, "Well, look. I can breathe free oxygen long enough to make the 100 foot ascent, but can I breathe it for too long?" They told us that if you breathed free oxygen long enough, you'd get a bubble in your blood stream, and when it hit your heart, you'd be gone.

INTERVIEWER: That's an embolism.

MR. DECKER: That was what we were told. One of the guys was commenting about that when we got ready to put the lungs on and everything. I said, "What other choice do we have with 180 feet? Let's go for it."

INTERVIEWER: Well, thank you very much for coming in.

MR. DECKER: You bet.

INTERVIEWER: Thank you.

MR. DECKER: I thank you all. Hey, you people back here made this little man's day, believe me.

INTERVIEWER: Oh, you bet. You made our days. You made our weeks. We've been glad to do that for you. Oh yes, indeed. Thank you very much, sir. We appreciate it.

# **Closed-Circuit Oxygen Diving in the U.S. Navy**

**CAPT Frank K. Butler, Jr.  
Naval Special Warfare Command  
Detachment Pensacola**

**25 September 2002**

The pioneers of modern closed-circuit oxygen attack swimming were the Italians. In the early days of World War Two, the Italian Navy found itself lacking the surface warfare power of other nations. In an effort to overcome this deficiency, they developed a cadre of intrepid naval commandos who attacked ships riding on torpedoes and using closed-circuit oxygen underwater breathing apparatuses (UBAs). The Italians had been evaluating these methods of underwater sabotage as early as 1918. (1) Operating against overwhelming odds, these commandos damaged 2 British battleships in Alexandria Harbor in 1941, the HMS Queen Elizabeth and HMS Valiant. (2, 3) Later, operating from an Italian tanker, the Olterra, that had been scuttled in 1940 but was later floated and moored in Algeciras harbor, Italian frogmen attacked allied shipping in Gibraltar in 1942/43 and damaged a number of ships. (1)

British frogmen had a measure of success in this area as well, sinking six Italian ships in Sicily in 1943 and the Japanese cruiser Takao in the Johore Straights. (Clark Presswood – personal communication) The biggest British success was the operation against the Tirpitz on 22 Sept 1943. (1) The Tirpitz was one of the most powerful vessels in the German fleet. It was anchored at the innermost end of the 20-mile Alten Fjord in Norway – a harbor protected by nets, mines, and listening posts. Three British mini-sub launched an attack on the harbor – two of the submersibles successfully penetrated the defenses and launched torpedoes. The Tirpitz was not sunk, but was incapacitated for 6 months. The crews of the midgets were captured.

At the start of World War Two, the United States Navy had no combat swimmer capability. Diving was performed using the deep-sea hard-hat rig in which the divers were confined to the immediate vicinity of the support vessel. Combat swimming for the purpose of clearing obstacles for an amphibious landing was not a recognized need. At this time, a medical student at the University of Pennsylvania named Chris Lambertsen was designing and building the United States' first closed-circuit oxygen SCUBA rig. Dr. Lambertsen was a first-year medical student in 1939 when he completed the initial prototype of his Lambertsen Amphibious Respiratory Unit (LARU). (4) He first dove his LARU prototype in 1940 in Lake Nokomis, near Minneapolis, Minnesota (5) to test the functioning of his new UBA. These were the first closed-circuit oxygen SCUBA dives in U.S. history. About 12 dives were accomplished, including one on which Dr. Lambertsen suffered an oxygen toxicity episode consisting of extremity and diaphragmatic twitching. Although he was tended from the surface, the line was improperly rigged and was dropped by the tender. Dr. Lambertsen managed to return to the surface under his own power. (Chris Lambertsen – personal communication) Dr. Lambertsen had a reasonably finished product by the end of 1940. He demonstrated the LARU to the U.S. Navy Experimental Diving Unit (NEDU) in October of 1940 (Chris Lambertsen – personal communication), but there was little interest in this new type of diving apparatus.

Undaunted, in November of 1942, Dr. Lambertsen demonstrated the LARU MK II to individuals who were in the process of forming a maritime unit for the Office of Strategic Services. This classified demonstration took place in the swimming pool at the Shoreham Hotel in Washington DC. The LARU was a distinct improvement over the British and Italian UBAs used at the time in that it had a one-way, recirculating gas flow design that provided much more

efficient carbon dioxide removal than the pendulum (or “counterlung”) design used by the Italian and British UBAs. The Browne UBA was also evaluated, but the LARU was judged the best UBA for use by the Maritime Unit. (5) Lambertsen’s UBA was called simply the “Lambertsen Lung” by the OSS swimmers who used it during the war, (Tom Hawkins – personal communication) with the LARU MK III being the UBA used early in OSS operations and the MK 10 replacing it shortly thereafter. On 17 May 1943, Dr. Lambertsen conducted the first closed-circuit oxygen dive training in this country in the pool of the U.S. Naval Academy. (5) The characteristics of the LARU used by these early OSS oxygen divers are shown in Table 1. (1) The LARU is shown in Figure 1. Dr. Lambertsen graduated from medical school in 1943 and was commissioned as a second lieutenant in the Army Medical Corps.

**Table 1: The LARU Closed-Circuit Oxygen UBA (1)**

 28 pounds  
 Full Face Mask  
 Oxygen cylinder - 2000 psi operating limit  
 Manual oxygen bypass  
 Over-the-shoulder breathing bag  
 Underwater gauge for oxygen bottle  
 Oxygen flow adjustable by needle valve

Also in May of 1943, the Chief of Naval Operations ordered the establishment of Naval Combat Demolition Units (NCDUs) made up of men trained as assault demolitioners to blow up obstacles placed on enemy beaches to prevent boats from coming ashore. (6) The Marine landing on Tarawa, where the landing boats were grounded on an offshore reef, resulted in a heavy loss of life and demonstrated the need for combat demolition swimmers in amphibious warfare. (6) LCDR Draper Kauffman, who was the Commanding Officer of the Navy Bomb Disposal School, was chosen to lead this new enterprise and he set up training for the NCDUs in Fort Pierce, Florida. LCDR Kauffman had originally been denied entry into the Navy because he failed the entrance eye exam. He then volunteered to serve in the war, first with the French Army ambulance service, where he won the Croix de Guerre, and then with the British bomb disposal units. Training at Fort Pierce started in June 1943. Lambertsen demonstrated the LARU to LCDR Kauffman in October 1943, but was again informed that there was no place in combat beach reconnaissance and demolition operations for this radically new device. (5)

Closed-circuit oxygen diving and combat swimming evolution in the United States continued, then, under the auspices of the OSS with Dr. Lambertsen leading the way. One of the major factors that divers using 100% oxygen UBAs must contend with is central nervous system (CNS) oxygen toxicity. The French physiologist Paul Bert had demonstrated that breathing oxygen at increased pressure could lead to convulsions and death. (7) Significant research had been done in this area by Dr. A.R. Behnke and his colleagues at NEDU as they explored the use of oxygen to accelerate decompression from long, deep dives and to treat decompression sickness. Following a series of chamber dives, Behnke and his colleagues published the first set of hyperbaric oxygen exposure guidelines in the U.S. military. (2,8) These guidelines are found

in Table 2. As we will see later on, had they been used as operational limits for OSS divers, the results might have been disastrous. Dr. Lambertsen displayed great insight in making the limits for OSS oxygen diving much more conservative than Behnke's chamber limits. Lambertsen's OSS oxygen exposure limits are shown in Table 3. (9) The increased conservatism in his tables at the deeper depths was not based on any personal observation that immersion and exercise increased the likelihood of oxygen toxicity, but from Lambertsen's realization that there would be a high probability of injury or death should a convulsion occur in a free-swimming diver. (Chris Lambertsen – personal communication)

**Table 2: Behnke Dry Chamber Oxygen Exposure Limits (2,8)**

Sea Level	4 hours
33 FSW	3 hours
66 FSW	3 hours
99 FSW	45 min

**Table 3: Lambertsen OSS Closed-Circuit Oxygen Exposure Limits (9)**

Sea level	24 hours
40 FSW	2 hours
60 FSW	45 minutes
100 FSW	10 minutes

Dr. Lambertsen also realized that more definitive limits needed to be established and requested additional guidance from the Navy Experimental Diving Unit after the war. (Chris Lambertsen – personal communication) This was a prescient action, because the OSS limits are still far less conservative than modern limits. The assertions made in the History of the OSS Maritime Unit (1) would find few subscribers today:

“Diving with the Lambertsen Unit is possible to depths as great as 100 feet. No diver should remain at that depth longer than 15 minutes at one time, however.... A more workable depth is from 50 to 60 feet at which the unit functions perfectly and permits submergence for 45 minutes without danger.” (1)

Despite these permissive deeper limits, the OSS had an excellent safety record diving oxygen during World War II, with very few toxicity episodes and no fatalities. (Chris Lambertsen – personal communication) This is probably due to Dr. Lambertsen's emphasis in training that the swimmers swim no deeper than required by the mission. Most of the diving was conducted between 20 and 25 feet. This chapter of U.S. closed-circuit oxygen diving history ended when the OSS was dissolved by President Truman on 1 October 1945. (10)

After the war, Dr. Lambertsen corresponded with CAPT O.K. O'Daniel to ask if NEDU had any guidance to provide on the subject of oxygen exposure limits for closed-circuit oxygen divers. CAPT O'Daniel responded on 30 September 1946 with the limits shown in Table 4 (11).

**Table 4: 1946 NEDU Oxygen Exposure Limits (11)**

Sea level	17 hours
30 FSW	2 hours
60 FSW	30 minutes

“ The 60 FSW limit has been set by both the United States and British navies.”

The pioneering work of Professor Ken Donald in the area of CNS oxygen toxicity in divers was conducted in the United Kingdom during World War II, but this work was not done until the latter part of the war and was not published after the war. (12) Donald decided that the risk of CNS oxygen toxicity mandated a maximum depth of 25 feet for closed-circuit oxygen divers. He was also the first to describe the role of water temperature, immersion, and exercise in reducing a diver's tolerance to hyperbaric oxygen.

In 1946 and 1947, perhaps inspired by the work of Donald and the experiences of the OSS Maritime Unit, Yarborough and Behnke at NEDU undertook the first tests of oxygen tolerance using immersed, working divers done in the U.S. (3,13) They attempted 71 exposures to 2 hours at 40 feet. 19 of the 71 exposures were stopped because of toxicity episodes. The UBAs used for this study were the LARU and the Browne units and the water temperature was 90 degrees F. At 50 feet, 3 of the 5 divers developed signs or symptoms of CNS oxygen toxicity. At 30 feet, they found that there were no toxicity episodes in 35 one-hour exposures, but two divers had symptoms at 87 and 111 minutes. (3,13) As a result of these investigations, the 1947 NEDU report stated that “For underwater work the safe inhalation of pure oxygen is limited to a depth of 30 feet.” No time limit was imposed.

In an effort to preserve the diving capability developed in the OSS Maritime Unit, Dr. Lambertsen had arranged to have custody of an inventory of LARUs transferred to him so that he could introduce OSS diving techniques to other groups. During the post-war period, Dr. Lambertsen introduced his diving apparatus to U.S. Army Engineers, the U.S. Coast Guard, and U.S. Navy Underwater Demolition Team (UDT) personnel. In 1947, the UDTs, under the leadership of LCDR Doug Fane, saw the advantages of having their members trained in the use of SCUBA gear for combat operations. This decision may have been hastened by receipt of the now-famous letter that Fane received addressed to “Underground Demolition Unit Two.” LCDR Fane proposed this training in 1947, but was informed by NEDU and the Navy Dive School that using this type of diving gear was too dangerous. (6) Undaunted, LCDR Fane invited Dr. Lambertsen to come to the Naval Amphibious Base in Little Creek, Virginia, in January 1948 to demonstrate the LARU to the UDT operators and conduct the first-ever training for Navy divers in SCUBA. (“self-contained underwater breathing apparatus” - a term coined by Dr. Lambertsen) (4,6,14)

Following this successful training, it was time to demonstrate for the Navy how closed-circuit oxygen diving might be employed in an operational setting. Since one of the most secure ways to insert combat swimmers was with a submarine, it was determined that this would be the next step. On 22 February 1948, Fane and Lambertsen accomplished the first free-

swimming, closed-circuit oxygen SCUBA lock-out and re-entry from an underway submarine (the USS Grouper) operating off the island of Saint Thomas, U.S. Virgin Islands. The sub was operating at periscope depth, so the lockout depth would have been approximately 30 feet. Although this would have been within the guidelines of the 1947 NEDU oxygen exposure limits, this was not a conscious factor in planning the dive, which lasted approximately 30 minutes. (Chris Lambertsen – personal communication)

After the success of the Grouper closed-circuit oxygen SCUBA operations, Fane returned to the UDT base in Little Creek and established a “Submersible Operations” or SUBOPS platoon with men drawn from UDT 2 and 4. (4) The activities of this group were extremely classified, even within their own organization. LTJG Bruce Dunning was the officer-in-charge of the SUBOPS platoon, which was the first unit with a SCUBA diving capability in the U.S. Navy.

Fane and Lambertsen next determined to do a study to better define the limits of safe oxygen exposures in free-swimming divers. They arranged a study at the Naval Submarine Medical Research Laboratory escape training tower later that year. This study was conducted by Schaefer and Willmon and was the first time that fin-swimming, LARU oxygen divers were observed in a study under controlled conditions. The divers swam a circular path in the tower at a speed of 0.9 knots in 90-degree water temperature. They did fifty dives with a maximum exposure time of 90 minutes at various depths and had 14 toxicity episodes. (4,6,15) This study also developed the Oxygen Tolerance Test, a 60 FSW for 30 minutes resting exposure in a dry chamber that was designed to test an individual’s tolerance for hyperbaric oxygen. No specific new Navy-approved oxygen exposure limits were established after the trials, however, leaving the 1947 NEDU limit of 30 FSW for an unlimited time as the most authoritative Navy oxygen diving limit at this time.

In October of 1948, Lambertsen and Fane conducted the second operational demonstration of closed-circuit oxygen diving capabilities. This time they were operating from the USS Quillback. The UDT divers were first all trained to operate on the deck of the underway submarine and to assist with rendezvous and recovery procedures. About 8 divers were trained. The dives were approximately 30 minutes in duration at a lockout depth of 30 FSW. Finally, the underway recovery of the British submersible canoe “Sleeping Beauty” aboard the Quillback was performed. Lambertsen positioned himself in the Sleeping Beauty ahead of the submarine on its course. He had a short bow line rigged from the bow to the cockpit of the Sleeping Beauty. After intercepting the submarine, which was towing a buoy, he threaded the Sleeping Beauty’s bow line through a metal loop on the towed buoy and then drove the craft down the line with the submersible’s power to the deck of the submarine. Losing only a stern plane to the sail of the sub, he maneuvered the Sleeping Beauty onto a cradle with the aid of the deck crew. The deck crew was out 30-40 minutes during the operation, again at a depth of approximately 30 FSW. (Chris Lambertsen – personal communication) These operations and the follow-on training demonstrated the feasibility of launching and recovering a free-flooding combatant submersible aboard an underway submarine and paved the way for modern-day SEAL Delivery Vehicle (SDV) and Dry Deck Shelter (DDS) operations. Figure 2 shows UDT members with their

LARUs.

After the successful Quillback combat swimmer operations and training, Fane briefed VADM Jerraud Wright at Amphibious Forces, Atlantic Fleet. He was stunned to receive official correspondence directing UDT to confine itself to conventional hydrographic reconnaissance and beach clearance. (4) Interpreting these orders somewhat creatively, Fane and Dunning continued to develop a submersible operations capability in the SUBOPS platoon. Perhaps appropriately, this training was headquartered in a building that had served recently as the base brig. The four UDTs on the East and West Coast used the LARU for submersible operations and training from 1948 into the early fifties. (Chris Lambertsen – personal communication)

The next event in the evolution of SCUBA diving operations in the U.S. Navy was the introduction of a new invention from France. Jacques Cousteau and Emile Gagnan had invented a new diving apparatus that they called the aqualung in 1943. The aqualung was different from the closed-circuit oxygen SCUBA used previously. The gas cylinders contained not oxygen, but compressed air. This apparatus was an open-circuit UBA, which meant that the diver's exhaled gas did not re-enter the UBA so that carbon dioxide could be removed and the unused oxygen rebreathed, but rather escaped to sea. The key bit of technology needed to make this breakthrough was Gagnan's redesign of a car regulator such that it could sense the ambient pressure the diver was exposed to and provide him with inhaled gas at a pressure that was slightly higher than ambient. Cousteau and others in the French Navy had made many dives with this new apparatus in the years that followed. Fane met with Gagnan and arranged for him to come to Little Creek in the spring of 1949 to teach the UDTs how to dive with the aqualung. (4) The aqualung had some advantages over closed-circuit oxygen UBAs: it was less complex, easier to set up, had a greater depth range, and reduced the possibility of diving accidents. These advantages led many UDT divers to have a strong preference for the new UBA in spite of the tactical advantages of the LARU. In one of the least distinguished chapters of UDT diving history, many of the remaining OSS World War II LARUs were consigned to a bonfire at a team beach party in 1953. (4,5,16)

The early fifties saw the UDT thus introduce open-circuit SCUBA into use in the U.S. Navy. Fane allegedly made the first dive by an American using the new UBA, diving to 100 feet on his first dive. (6) The aqualung was subsequently used by Fane to demolish a wreck in the Chesapeake Bay that was posing a hazard to navigation in December 1949. It was used by UDT in 1950 in Sleeping Beauty and other submersible trials. In 1952, a research program headed by Dr. Lambertsen conducted open-water trials in the waters off of Coronado, California with the aqualung and the LARU to study physiological limiting factors in underwater swimming. (4) This series of research dives was also notable in that it was the first use of the newly developed wet suits by the U.S. Navy.

Another factor that contributed to the unfortunate but temporary demise of closed-circuit oxygen diving in UDT was the July 1952 publication of the first closed-circuit oxygen diving limits in the U.S. Navy Diving Manual, which stated:

“When diving with a mask, oxygen should not be used at depths greater than 30 feet. The time of dive should not exceed 30 minutes.” (17) The 30-minute time limit was very restrictive and effectively put attack swimmers out of business, since most combat operations would entail much longer swims than this. This extremely restrictive limit was short-lived, however. Further research done at NEDU by Lanphier and his colleagues resulted in this overly conservative limit being changed. (3,18) Lanphier did 51 dives using 19 immersed, working divers at a variety of depths. The divers were breathing oxygen (averaging 99.5% purity) from an open-circuit source and the water temperature was 80 degrees F. The limits recommended by Lanphier in Table 8-2 of NEDU 11-54 report are shown in Table 5. (18)

**Table 5: Third NEDU Closed-Circuit Oxygen Limits - Lanphier 1954 (18)**

10 ft for 120 minutes  
15 ft for 90 minutes  
20 ft for 65 minutes  
25 ft for 45 minutes  
30 ft for 30 minutes  
35 ft for 20 minutes  
40 ft for 15 minutes

After several years, the UDTs began to reconsider their infatuation with open-circuit SCUBA. Closed-circuit SCUBA offered the advantages of being much smaller and lighter than open-circuit UBAs that would last for equivalent dive depths and times. Another important advantage was that there is no stream of tell-tale bubbles cascading to the surface as the diver approached a hostile ship or pier, a decided tactical plus. Since the LARUs were no longer serviceable, the UDTs acquired the World War II-vintage Italian Pirelli UBA in the years after the Korean War. (Norm Olson – personal communication) The foremost individual credited with bringing closed-circuit tactical diving back to the teams was LCDR Frank Kaine during the time that he was Commanding Officer of UDT 21 in Little Creek, Virginia but the West Coast UDTs also acquired and used the Pirellis. (Layton Bassett – personal communication)

As shown in Figure 3, the Pirelli was a pendulum-type rebreather, in which a single hose was used both to inhale from and exhale to the CO<sub>2</sub> scrubber and the breathing bag. The characteristics of the Pirelli are listed in Table 6. (19)

**Table 6: Description of the Italian Pirelli (19)**

LS-901  
Pendulum system  
Two 1.6 liter bottles of oxygen  
Each oxygen bottle charged to 3000 psi  
Constant flow regulator adjustable from 0.5 to 2 L/M flow  
Lasted for up to 4 hours under normal working conditions  
CO<sub>2</sub> absorbent canister inside the breathing bag

Pendulum type rebreathers have an inherent design flaw. The gas flows to and from the

scrubber and the breathing bag via the same hose, creating a “dead space” in the loop that contributes to CO<sub>2</sub> buildup. While this may not be a problem to divers who are breathing from it while riding on submersibles, it quickly becomes a problem for free-swimming divers. The Pirelli was given the nickname “The Black Death” because of the numerous CO<sub>2</sub> and oxygen toxicity episodes suffered by team members while diving with this rig. (Layton Bassett – personal communication) After a near-fatal accident with the Pirelli in 1956, UDT operator Harold Nething recalled:

“...after some investigation, it was discovered that in the breathing bag where the scrubber canister attached to the breathing hose, there’s a fitting that’s sweat soldered on....it had parted and failed. Later, after testing all the Pirellis, about 85% failed.” (Harold Nething – Internet site)

These problems were reported to the Bureau of Ships. (20) Further investigation by NEDU resulted in a recommendation that no more Pirellis be procured. (21) Use of the Pirelli decreased in 1956 and 1957 and this UBA was soon replaced by the initial German Draeger. A picture of the German Draeger UBA is shown in Figure 4 and its characteristics are shown in Table 7. (19)

**Table 7: Description of Draeger LT Lund II (19)**

Draegerwerk, Lubeck, Germany  
Two oxygen cylinders – 0.8 liters each  
Charged to 2800 psi  
Total gas supply of 320 liters (11.2 cu ft)  
Constant flow regulator set to provide 0.9 L/min O<sub>2</sub>  
Also had manual oxygen bypass  
CO<sub>2</sub> absorbent canister was inside breathing bag  
Operating limit 90 minutes

The Draeger LT Lund II UBA had an excellent reputation in the UDTs (Norm Olsen and Layton Bassett – personal communications). Weber stated that “Most of our divers prefer the Draeger to other rebreathers due to simplicity of design and reliability of operation.” (19) The Draeger was used only for several years (approximately 1957-1958) due to lack of replacement parts and subsequent maintenance problems. Subsequently, Scott Aviation reverse engineered and built a U.S. version of the Draeger. While externally, it looked the same, it did not achieve the quality of the German version and was shelved shortly thereafter. (Norm Olson – personal communication)

In the early 1950s, Dr. Lambertsen worked with the J.H. Emerson Company to develop the LARU MK 20 UBA. They introduced this updated UBA first to the Army. (Chris Lambertsen – personal communication) The LARU MK 20 was eventually modified and introduced into the Navy as the Emerson-Lambertsen UBA in about 1963. (19) One major difference between this UBA, which came to be called simply the Emerson in the teams, and the LARU series was that the Emerson was typically used with a T-bit mouthpiece and a partial

facemask that was isolated from the breathing loop. The LARU had been used with a full facemask by the OSS swimmers and the initial Army and Navy trainees. There are two primary advantages to using a full facemask with closed-circuit SCUBA: the airway is better protected in the event that the diver should become unconscious from oxygen toxicity or other diving disorder and the diver is better able to use underwater communication devices for operational or emergency communications. The Emerson-Lambertsen was also a recirculating system as opposed to the flawed pendulum design of the Pirelli, and had over-the-shoulder breathing bags, which have the advantage of being comfortable to breathe in both prone and sitting positions. One aspect of the rig that was not ideal was the 3-setting metered oxygen supply valve design. If the diver's oxygen consumption changed underwater, he might find himself with insufficient oxygen to breathe and would have to use the manual bypass valve. Conversely, if his oxygen consumption was lower than the add rate, his bags would overfill with oxygen and he would experience an undesired increase in buoyancy. (Don Crawford – personal communication) A description of the Emerson-Lambertsen UBA is provided in Table 8 (19) and a picture of this UBA is shown in Figure 5.

**Table 8: The Emerson-Lambertsen Closed-Circuit Oxygen UBA (19)**

Metered oxygen flow valve – 0.5, 0.9, 2.0, or 3.0 L/M

Cylinder charged to 2000 psi

Capacity 360 L (12.7 cu ft)

Normal duration of the apparatus is 120 minutes

The Emerson-Lambertsen served the teams well for almost 20 years, from 1963 until approximately 1981. By that time, replacement parts for the UBA had become very hard to obtain. Rigs were cannibalized for spare parts, maintenance was difficult, and increasing numbers of the rigs began to malfunction. By 1980, the problem had become severe and the Emerson was declared no longer usable by Naval Special Warfare. (Don Crawford – personal communication)

The demise of the Emerson meant that the UDT and now the SEA/Air/Land (SEAL) teams were in need of a new closed-circuit oxygen UBA. NEDU evaluated both the German Draeger LAR III (“LAR” is an acronym for “Lung Automatic Regenerator”) (22) and the LAR V (23) closed-circuit rebreathers as potential replacements for the Emerson-Lambertsen. The rig selected after NEDU testing was a modified version of the LAR V. This UBA was introduced into the Naval Special Warfare community in 1981, with the first 10 units going to SEAL Team Six, and others following quickly to the other teams. (Don Crawford and Rick Woolard – personal communications) The LAR V has several advantages over the previously used Emerson-Lambertsen. At 25 pounds, it is significantly lighter. It is also smaller, simpler in design, and has (as did the LARU MK 20) a well-designed oxygen add system in which a second stage demand regulator opens any time that the diver empties all the air from his breathing bag. A description of the Draeger LAR V is provided in Table 9 (24) and a picture of this UBA is shown in Figure 6. This UBA is still the primary UBA used by Naval Special Warfare in 2002. Renamed the MK 25, it has been recently modified to include a larger oxygen bottle and a larger, better insulated CO<sub>2</sub> absorbent canister (MK 25 MOD 2). (24)

**Table 9: The Draeger LAR V/MK 25 MOD 2 UBA (24)**

Length:	18 inches
Width:	13 inches
Height:	7 inches
Weight:	27 pounds
Buoyancy:	Neutral
O2 Cylinder:	1.9 L O2 at 3000 psig
Chest-mounted	
Fiberglass housing	
Bypass add rate:	60 liters/min
Oxygen addition by demand	
No constant addition of oxygen	

Although the Teams got their new UBA from the Germans, they took many of their combat swimming tactics from the French via SEAL Team TWO. Combat swimming had become an area of decreased emphasis during the Vietnam war, where the SEALs and UDT became jungle warriors. Many SEALs, including then-CDR Bob Gormly at SEAL Team Two, recognized the need to re-establish the SEAL's expertise in the water. LT Ryan McCombie, recently returned from Vietnam, was sent to France for an exchange tour with the French Commando Hubert in St Mandrier. There he was exposed to a totally different diving culture. During this period, the Commando Hubert were arguably the best combat swimmers in the world. Their training typically entailed 5-7 dives per week. The dives were complex, multi-dogleg and long duration.

During the 6 month French basic training, Lt McCombie with Lt Jean Francois Tardiveau as a swim buddy, completed a 7000 meter, 4hour 10 minute closed-circuit oxygen dive. This particular dive was remarkable, even for the Commando Hubert, and demonstrated what could be accomplished with the proper training and equipment. Now-LCDR McCombie returned from France with a clear vision of how Naval Special Warfare could enhance its combat swimming skills.

He was to have an opportunity to act on this vision. Several years later, CDR Rick Woolard assumed command of SEAL TeamTwo2 and LCDR McCombie was his Executive Officer. CDR Woolard had been embarrassed by a poor showing of SEAL attack swimming abilities during a "Flintlock" combat exercise with German and Dutch counterparts in 1981. He also had great respect for French oxygen diving capabilities. While Executive Officer of SEAL Team TWO, McCombie had arranged for a Hubert officer to be assigned there. LT Francois d'Avout reported to SEAL Team TWO shortly after Woolard assumed command in 1982, and Woolard immediately directed McCombie and d'Avout to develop and conduct a course in attack swimming to correct the SEAL operational deficiency. The resulting eight-week Combat Swimmer Course stressed accurate underwater navigation, precise buoyancy control, long-distance underwater and surface swimming ("turtlebacking"), and full-mission profiles that realistically integrated the attack swim into stealthy air/land/water target approach and withdrawal scenarios. The instructors and students were carefully selected, and all graduates had

to show they could approach, attack, and withdraw from targets miles from their dive point without surfacing despite multiple underwater course changes. In 1983, Woolard's efforts were rewarded when his SEALs successfully completed a long and very arduous attack swim during a major exercise in Germany...and their German counterparts did not. From then on, Combat Swimmer Course graduates routinely outperformed their European counterparts, and by the late 1980s they were teaching attack swimming to the Germans and others. The course was eventually accepted by the Naval Special Warfare community as a major improvement in SEAL capabilities, and its primary lessons are still part of both the Basic Underwater Demolition/SEAL and SEAL Qualification Training courses that every SEAL must complete." (Ryan McCombie and Rick Woolard – personal communications) Figure 7 shows SEAL team members on a combat swim using the Drager LAR V.

The Navy oxygen exposure limits had also evolved over time. New limits appeared in the 1959 Diving Manual that were modified somewhat from those proposed by Lanphier. The 1959 limits are shown in Table 10. (25) No experimental basis was identified for these changes to Lanphier's 1954 recommendations.

**Table 10. 1959 U.S. Navy Diving Manual Oxygen Exposure Limits (25)**

10 ft for 240 minutes
15 ft for 150 minutes
20 ft for 110 minutes
25 ft for 75 minutes
30 ft for 45 minutes
35 ft for 25 minutes
40 ft for 10 minutes

By 1981, the USN oxygen exposure limits had been modified further as shown in Table 11. Note that the 240-minute limit for dives 10 feet and shallower as well as the 150 minute limit for dives 15 feet and shallower had both been dropped. Again, the reasons for these changes from previous limits were not documented in the Diving Manual. (26)

**Table 11. 1981 U.S. Navy Diving Manual Oxygen Exposure Limits (26)**

20 ft for 110 minutes
25 ft for 75 minutes
30 ft for 45 minutes
35 ft for 25 minutes
40 ft for 10 minutes

For the SEALs to utilize their new Draeger Vs and newfound combat swimming skills, the advance in oxygen diving required next was the establishment of less restrictive closed-circuit oxygen exposure limits. Increasing contact with combat swimmers in allied countries found that their oxygen exposure limits were less restrictive in those in the U.S. Navy. In 1981, Naval Special Warfare requested that NEDU re-evaluate the oxygen exposure limits to see if longer exposures might be safely

accomplished. NSW also requested that NEDU evaluate the feasibility of making a brief downward excursion after a lengthy exposure at a shallow “transit” depth. This request resulted in 3 major dive series conducted by Butler and Thalmann at NEDU between 1982 and 1984. (27,28,29) Divers were immersed, exercising, and subjected to moderate cold stress in an attempt to create reasonable “worst-case” conditions for operational combat swimmers. Experimental divers used the same Draeger LAR V UBAs then in use by the SEAL teams. The UBA was purged to achieve a minimum oxygen fraction of 95% before the exposure was started and CO2 levels were constantly monitored to ensure that there was no CO2 build-up, which would make the divers more susceptible to oxygen toxicity.

The trials began by re-evaluating the 40-foot exposure limit. A 20-minute exposure at this depth produced 2 convulsions in 17 dives while a 15-minute exposure produced no convulsions or definite symptoms of CNS oxygen toxicity in 41 exposures. (27) A 15-minute excursion was then attempted following a two- hour “transit” period at 25 feet. This profile produced 2 definite hits on the previously safe 40-foot excursion and one convulsion at 25 feet. After consultation with operational SEAL units, the transit depth was reduced to 20 feet and the testing resumed. (28)

The second set of dive trials finished re-evaluating the single-depth oxygen exposure limits. The new single-depth oxygen exposure limits proposed after this series (28) and displayed in Table 12 were approved for use in Naval Special Warfare in 1983 and are still in effect in 2002. (30)

**Table 12: Current USN Single-Depth Oxygen Exposure Limits (30)**

25 FSW or shallower	240 minutes
30 FSW	80 minutes
35 FSW	25 minutes
40 FSW	15 minutes
50 FSW	10 minutes

The second set of dive trials also found that a 20-foot oxygen exposure for periods of up to 4 hours did not adversely affect the diver’s ability to make a brief downward excursion. (28) The current U.S. Navy Transit with Excursion limits are shown in Table 13; they were also approved for use in 1983 and are still in use in 2002. (30)

**Table 13: Current USN Transit with Excursion Limits (30)**

- Transit portion of dive 20 FSW or shallower
- Single excursion allowed
 

21-40 FSW	15 minutes
41-50 FSW	5 minutes
- Total dive time 240 minutes or less

A third NEDU oxygen dive series was conducted in November and December 1985 and was designed to evaluate the feasibility of making multiple downward excursions from 20 feet on a 4-hour dive. (29) This series encountered an increased incidence of toxicity episodes in attempting multiple excursions on a single dive and no modification to the single-excursion rule was proposed. (29) A total of 686 dives were accomplished during the three series with 67 episodes of in-water CNS oxygen toxicity, including 8 convulsions.

On the protocols above, a single toxicity episode was seen on the 25 and 30-foot depths within an exposure time that was completed by many other divers without incident. Both divers suffered multiple toxicity episodes during the dive series and were considered to be more sensitive to the effects of hyperbaric oxygen than their fellow experimental divers. Since both divers had passed the oxygen tolerance test (OTT) as part of their screening for diver training, the sensitivity of this test in identifying individuals who are unusually susceptible to oxygen and its usefulness as a screening tool was questioned. This issue was addressed by Butler and Knafelc following the NEDU oxygen dive trials. (31) They identified three divers that had had multiple episodes of oxygen toxicity on profiles other divers had performed without difficulty. They then performed multiple OTTs on these individuals to see if the test was sensitive enough to identify any of the divers as sensitive on multiple exposures. None of the divers had symptoms on any of the OTTs, leading the investigators to conclude that the failure of the OTT to elicit symptoms of CNS oxygen toxicity in these divers was reproducible. The next question addressed was how many individuals fail the OTT (have signs or symptoms of CNS toxicity within the 30 minutes at 60 feet). A review of the records from the Naval Safety Center revealed a 1.9% failure rate among diving candidates undergoing the OTT. Since the individuals identified as sensitive to oxygen during the NEDU dive trials had repeatedly passed the OTT, the 1.9% of individuals who failed the OTT on the first trial were considered to be perhaps even more sensitive to oxygen. The authors therefore recommended that the OTT be retained for any divers who would be using closed-circuit oxygen because of the high probability of a fatality resulting from a convulsion that occurred while engaged in untethered diving. (31)

The issue of approving oxygen exposure limits that had been shown to produce CNS oxygen toxicity was a contentious one, especially in light of the single convulsion that occurred at 25 feet after only 72 minutes, when many other divers were able to tolerate 4 hours at this depth without incident. Professor Donald commented some years later:

“The present author would strongly oppose the acceptance of the possibility of acute oxygen poisoning in the oxygen exposure time limits recommended for routine diving operations. Such an acceptance could impair the traditional and essential trust between divers and those responsible for their safety.” (3)

The safety of the new limits was greatly enhanced by a SEAL corpsman who inquired in 1983 about the rationale for the purge procedure used at the time. (Master Chief Johnny Johnson – personal communication) The Draeger LAR V purge procedure in use in 1983 was to manually fill the breathing bag with oxygen and then empty it by inhaling through the mouth and exhaling

through the nose three times on the surface before the dive. The UBA was also purged every 30 minutes during the dive to protect against dilutional hypoxia occurring as the tissues of the body off-gassed nitrogen. A review of NEDU reports and the Navy Diving Manual revealed no explanation of why that particular volume of purging had been chosen nor any measurement of the oxygen fraction produced in the UBA by the procedure. (32) The procedure used by Lambertsen in the OSS and in the initial training of Navy UDT and Army cadres prior to diving the LARU was as follows: "...sucking the bag completely flat and closing the mask shut-off valve. O<sub>2</sub> could be added to the bag or not. Then, when ready to dive (could be an hour or more later), a full exhalation of air from lungs, and switch to O<sub>2</sub> rebreathing. No O<sub>2</sub> flushing of the unit was done. Any later gas venting supplemented this by accident and not intent." (Chris Lambertsen – personal communication) This procedure was used throughout World War II and apparently served well. The origins of the three-cycle fill and empty and the every-30 minute during the dive procedure that came into Navy use later remain obscure.

In rethinking the purge procedure at NEDU following Master Chief Johnson's question, Butler and Thalmann determined that the purge should seek to achieve a level of oxygen in the UBA only high enough to prevent hypoxia. This level was determined to be 45% for a purge being done on the surface (32) and 55% for a purge being done at depth. (33) A single fill/empty cycle of purging prior to the dive was found to be sufficient to ensure this level of oxygen in the UBA and to produce a mean value of 71% FIO<sub>2</sub> (fraction of inspired oxygen) on the surface. Purging nitrogen out of the rig beyond this level serves only to increase the risk of CNS oxygen toxicity and consume gas from the UBA cylinder, thereby shortening the gas supply available for the mission. The mean oxygen percentage in the UBA was found to increase to a mean of 82% as the diver descends to a depth of 20 FSW to begin his swim. Additional purging conducted during the dive was found to be unnecessary for hypoxia prevention, to consume additional gas, and to potentially compromise the diver's position if his bubbles are observed by hostile forces on the surface.(32)

This seemingly modest decrease in FIO<sub>2</sub> may be of great importance to the safety of the diver. Using a probabilistic model, Harabin and her colleagues at NMRI showed that the risk of developing CNS oxygen toxicity from breathing "nearly pure" oxygen at 30 feet for 80 minutes is about 4 %. If the recommended new purge procedure is followed, however, resulting in a lower FIO<sub>2</sub> of 0.74, the probability of toxicity after 80 minutes is less than 0.1% (34) How safe have the 1983 oxygen exposure limits proven in practice? Walters et al addressed this issue in their 2000 paper. (35) A review of the records from the Naval Safety Center found 157,930 LAR V dives with only one reported episode of oxygen toxicity.

Many SEAL operations, including ones that entail closed-circuit oxygen diving, are carried out in secret and never become public knowledge. One exception to this rule is the ship attack that was carried out during Operation Just Cause in Panama in 1989. (16)

CDR Norm Carley, Commanding Officer of SEAL Team Two, was directed to attack three Panama Defense Force (PDF) gunboats prior to the larger assault. The planners for Just Cause wanted to avoid major damage to the vessels so that they could be used by the new

Panamanian government, but CDR Carley convinced them that this would entail unacceptable risks to the SEAL operators involved. The operation was complicated by several additional factors. The patrol boats were made of aluminum, so limpet mines would not stick to the hulls. The attack was instead carried out with haversacks of C-4 plastic explosives.

Cutting across the Panama Canal, the two SEAL combat rubber raiding crafts (CRRCs) ran into unanticipated boat traffic north of Balboa Harbor, including some boats with spotlights. The CRRCs, running at low speeds so not to leave a wake, avoided detection. Arriving at the far shore early, the CRRCs hid in a mangrove tree line north of Balboa Harbor while waiting to insert the SEALs. Two boats left Balboa Harbor, but the Presidente Porres remained at the pier. After 15 minutes, CRRC #1 started its motor and began creeping out of the mangrove. CRRC #2's outboard motor had quit, and it was thus unable to follow. Carley, aboard CRRC #1, decided to proceed to the insertion point alone. The CRRC advanced out of the mangrove, headed a few hundred yards in a southeasterly direction, and quietly approached a position 150 yards north of Balboa Harbor's Pier 18. With a backdrop of the darkened mangrove, the CRRC approached without being detected. A pair of SEALs, LT Edward Coughlin and EN3 Timothy Eppley, slipped over the CRRC's side at 2330, went underwater, and started toward their target. CRRC #1 withdrew, returned to the hideout, slipped a tow line to its disabled sister, and headed out of the mangrove. Together they proceeded to the insertion point off pier 18, where the second swimmer pair, ET1 Randy Beausoleil and PH2 Christopher Dye, quietly left CRRC #2. Swimming underwater, the second pair was five minutes behind the other two swimmers. To destroy the target, each swimmer pair was equipped with a 20-pound Mark 138 Haversack explosive package with a MCS-1 clock, a Mark 39 Safety and Arming Device, and a Mark 96 detonator.

After the SEALs were inserted, Carley ordered that CRRC #2 be towed back to NS-Rodman so that its outboard motor could be changed. Although the CRRC had a spare outboard motor on board, Carley felt that it was too risky to attempt an engine change out on the water, given the CRRCs' proximity to the target and the level of activity around Balboa Harbor. Besides, the starting process of the outboard motor was loud and sure to alert the PDF. Avoiding a compromise of the SEALs swimming to the target was uppermost in Carley's mind. On the return to NS-Rodman, the CRRCs evaded two more craft going across Balboa Harbor. The remainder of the assault force arrived at NS-Rodman and began changing CRRC #2's outboard motor. Carley observed the target area for indications that the PDF might be alerted. Balboa Harbor appeared quiet. The pairs of SEALs, swimming underwater on a compass bearing, approached pier 18. It became apparent to the swimmers the marine effect of bioluminescence was playing havoc with their ability to read watches, depth gauges, and compasses. Underwater navigation was difficult. Surfacing under the pier, the swimmer pairs used it as overhead cover as they alternated between surface and underwater swimming to reach the inner part of Balboa Harbor. As the SEALs reached toward the shore end of the pier, they saw the PDF patrol boat was moored by its stern to a nearby floating dock adjacent to a quay wall and its bow pointed out into Balboa Harbor. The SEALs dove and approached the target underwater. Swim pair #2, ET1 Beausoleil and PH2 Dye, swam underneath the target at 0011, 20 December. It took them two minutes to attach the haversack of explosives to the port propeller shaft just forward of where the

"V" strut held the shaft. They then began swimming south to pier 17. The other pair of SEALs, LT Coughlin and EN3 Eppley, arrived on target a minute later and attached a haversack to the starboard propeller shaft near the "V" strut. These SEALs finished the arming sequence of the demolition charges--the detonator cord leads between the two charges were tied to ensure dual priming--and set the charges to explode at 0100. The SEALs had 45 minutes to exfiltrate a safe distance from the target.

Just as Coughlin and Eppley swam away, the patrol boat's engines started. The propellers were not engaged and the boat remained stationary. Tonight, unlike previous nights, some PDF crew were aboard the patrol boat. The second pair of SEALs also swam underwater to pier 17. Following the contour of the pier for concealment, the SEALs swam away from the target. With the advancing of H-Hour, battles had started in Panama City with the attack on the Comandancia. Shortly afterwards, the SEALs were subjected to two intense underwater explosions. The SEALs, afraid they were compromised and under an anti-swimmer grenade attack from PDF soldiers patrolling pier 17, surfaced and hid behind pilings to escape injury. Continuing to move under the pier, the SEALs alternated between surface and underwater swimming to conserve oxygen in their Draeger systems. A couple of hundred yards further, four more underwater explosions forced the SEALs to surface again and take refuge behind the pilings. Although firing was heard overhead and tracers were seen arcing toward the Panama Canal, it did not appear to be directed at the SEALs.

Both pairs of SEALs were behind pilings under pier 17 when at precisely 0100 the charges underneath the Presidente Porres detonated. "The boat reared up forward . . . it went straight up--the bow went up," recalled LT Michael Argo, who observed the explosion through high powered binoculars from Naval Station Rodman. The explosion blew a hole ten feet wide through the hull and deck, destroying the stern of the boat. The engine room was a complete loss. The boat flooded and sank within two minutes. The floating dock next to the patrol boat, its steel floats punctured, swamped with water the next day.

Shortly after the explosion, most boats in Balboa Harbor started their engines and turned their propellers as an anti-swimmer attack measure. The SEALs were behind schedule to make the extraction point and rendezvous with the CRRCs to be taken back to NS-Rodman. The extraction point was located at the south end of pier six, a structure 500 yards south of Balboa Harbor, and a distance that the swimmer pairs could not arrive at by the previously planned time of a few minutes after H-Hour. Prior to H-Hour, the swimmers had tried to establish communications with TU-WHISKEY to say they were behind schedule. But the radios were malfunctioning. After the explosion, the SEALs pairs started moving again, heading to the end of pier 17, on a course toward the extraction point. Swimming a course to reach pier 6 took the SEALs near the main shipping channel of the Panama Channel. As the SEALs swam into the Panama Canal, a strong current of six knots running in the direction of the Pacific Ocean nearly swept them off course. Just then a deep-draft ship was making its way through the Panama Canal shipping channel. As Coughlin recalled, "You can't tell under the water exactly where a vessel is; you just hear it getting louder, and louder--it sounds like a freight train coming." With the ship approaching, the SEALs descended to 45 feet to avoid being drawn into the propellers.

The increased toxicity of the pure oxygen in the Draeger system in deeper water was risky. Alternatives, however, were lacking. The SEALs remained at this depth for 10 to 15 minutes until the ship passed overhead. They then ascended to 20 feet, the normal depth for the Draeger system, executed a turn, and swam on a bearing for pier 6. Reaching the pier separately, the swimmer pairs surfaced, used the pier as overhead cover to swim on the surface, and reached the extraction point at its southern end.

Meanwhile, as the swimmer pairs were making their way under pier 17, the CRRC crews replaced CRRC #2's outboard motor. The engine change took just a few minutes. At 0045, both CRRCs departed NS-Rodman and arrived at the extraction point ten minutes later. They hid under the pier, eight to nine feet above their heads, as firefights erupted in the vicinity between PDF and American forces. A few minutes later the harbor shook from the explosion under the patrol boat. The CRRCs waited but the swimmers did not appear at the designated extraction time. CDR Carley sent CRRC #2 to the next pier over to search for the SEALs in case they had missed the extraction point. CRRC #2 returned reporting no sign of the SEALs. The CRRCs continued their vigil at the extraction point. An hour passed before the first SEAL pair, Coughlin and Eppey, arrived at 0200. The other pair, Beausoleil and Dye, made it to the extraction point five minutes later. The SEALs were recovered and the CRRCs headed back to NS-Rodman. As the assault force cleared the far shore and went across the Panama Canal to NS-Rodman, infrared strobes onboard the CRRCs were turned on to help U.S. forces recognize the CRRCs as a friendly unit. A message was transmitted to TF White stating that the SEALs had been recovered and Task Unit-WHISKEY had executed its mission without casualties. (Norm Carley – personal communication)

Butler and Knafelc suggested in their 1986 paper (31) that the incidence of OTT failures was suspicious based on a smaller than expected number of OTTs reported. Walters et al reviewed records from the primary chambers administering the OTT to Navy SEAL candidates and found that the incidence of failure of the OTT was only 0.096%, much lower than previously reported. (35) The conclusions and recommendations from this paper were:

- 1) The failure rate for the OTT as it is currently administered in Naval Special Warfare is 0.096%. This number is approximately 5% of the previously reported incidence of 1.9%, which was based on data from the Naval Safety Center.
- 2) The logistic burden of administering the OTT had caused testing to be currently conducted after the SEAL students have completed the most rigorous 9 weeks of SEAL training. Disqualification of a SEAL candidate at that point in training should be based on clear and compelling evidence that he is unfit to continue training. The OTT does not meet that standard.
- 3) Even if a more severe OTT were to be developed, intra-individual variability prevents any single screening test from being a reliable indicator of increased oxygen sensitivity.
- 4) Factors other than individual oxygen tolerance such as a high exercise rate, diver hypoventilation, canister failure, inadvertent depth excursions, inadequate thermal protection, or excessive purging of the UBA may contribute more to the risk of operational oxygen toxicity than individual sensitivity. (36)
- 5) Naval Safety Center dive reporting procedures should be modified to document all suspected episodes of oxygen toxicity which occur on closed-circuit oxygen dives. This should

include a reporting format that provides for the maximum capture of pertinent data to facilitate accurate and reliable determinations of the CNS oxygen toxicity incidence in operational diving.

6) In light of items 1 through 4 above, the authors recommend discontinuation of the OTT as a screening test for Navy Seal candidates. The OTT was discontinued as a screening test for NSW candidates in April of 1999. (37)

Another significant advance in oxygen diving in the Navy was accomplished as a result of establishing UBA and oxygen exposure limits for resting as opposed to swimming divers. This physiological situation applies primarily to SEALs who are piloting or riding in SDVs. These free-flooding submersibles, whose operating characteristics are classified, are capable of transporting SEALs over long distances underwater. Since these divers have a much lower rate of oxygen consumption and CO<sub>2</sub> production, their gas supply and canisters should both last longer and the risk of CNS oxygen toxicity should be lower. This realization in 1996 resulted in the Naval Special Warfare Command initiating tasking for NEDU to re-evaluate limits for both the Draeger LAR V and the SEAL operator at 20 feet in a mostly-resting scenario. Marino and Maurer tested 8-hour dives in 76-81 degree F. degree water and found that all canisters were still adequately removing CO<sub>2</sub> after 8 hours. (38) Approximately 25% of the UBAs had to have oxygen bottles replaced before the end of this period. There were no episodes of CNS oxygen toxicity although a number of divers displayed early symptoms of pulmonary oxygen toxicity. New limits were subsequently established by NAVSEA for this UBA which remain classified, but are significantly longer than allowed by the previous limit. (39) At shallow depths, pulmonary oxygen toxicity or UBA limits may be the limiting factor for exposures rather than CNS oxygen toxicity. (38,39,40)

Current research in oxygen diving in the U.S. Navy has focused on the development of deep water Draeger LAR V lockout procedures for the Advanced SEAL Delivery System (ASDS). The ASDS is a new submersible that transports SEALs close to their intended target in a dry, one-atmosphere environment. At their lockout point, the SEALs exit the ASDS and begin a combat swim for their final approach. The maximum lockout depth is classified, but is in excess of 100 feet. Operational units using this craft requested that a procedure be developed whereby missions requiring deep-water lockout could be accomplished using a Draeger LAR V rather than a bulkier and more complex closed-circuit mixed-gas UBA. A proposed procedure has been developed in which the divers breathe chamber air and vent the UBA rig to equalize pressure during compression. They then exit the lockout hatch breathing from the submersible's built-in hookah rigs until they reach the ascent line. Once ready to ascend, the divers swim toward the surface inhaling through the mouth and exhaling through the nose. This serves to vent the expanding gas from the UBA and to provide the diver with compressed air to breathe during the ascent. The oxygen valve is closed until the diver reaches 15 feet and carries out an underwater purge. He then begins his swim with a purged UBA. This procedure was proposed by the Naval Special Warfare Command in 2001 (41) and has been successfully tested by NEDU in controlled conditions. (42) Open water testing is anticipated in 2003.

It is a noteworthy observation that Dr. Lambertsen was a member of the ASDS Medical

Advisory Panel that developed the procedure described above, thus resulting in his contributions to closed-circuit oxygen diving spanning the entire history of the U.S. Navy experience in this area. Another important observation is that the Naval Special Warfare community was responsible not only for the introduction of closed-circuit SCUBA diving to the Navy, but for the first employment of open-circuit air SCUBA as well.

The author is grateful for the substantial help provided by Dr. Chris Lambertsen, CAPT Mike Curley, former SEAL Dr. Dick Vann, and retired SEALs CDR Tom Hawkins, CAPT Norm Olson, CDR Don Crawford, CAPT Rick Woolard, CDR Norm Carley, CAPT Ryan McCombie, CDR Rick Bernard, CAPT Tim Holden and Master Chief Layton Basset during the preparation of this paper.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF DAVID ANDREWS, EN1, (DV) USN

Kensington, Maryland

Thursday, September 4, 2003

## PROCEEDINGS

INTERVIEWER: I'm at the Navy Special Clearance Team One with Engineman First Class David Andrews, an Explosive Ordnance Disposal (EOD) technician who was with the unmanned underwater vehicles during Operation Iraqi Freedom. How long have you been in the Navy?

EN1 ANDREWS: I'm going on 13 years now. It's 12 years and change, at this point in time. It'll be 13 years come October.

INTERVIEWER: After EOD School, where did you go?

EN1 ANDREWS: I was in the 31 Program, so that was the first part of my training. I went out, came into the Navy, went to boot camp and then to my A School, which was Engineman A School at the Great Lakes Naval Training Center in Illinois. After that, I was assigned Temporary Additional Duty (TAD) to EOD Mobile Unit 2 to get in shape for dive school, for a period of two to three months.

I went to dive school and then to the first part of EOD training. From there, I was stationed at EOD Mobile Unit 9 in Vallejo, California. I stayed there for about two years, in San Francisco for the majority of my time. From there, I went back to EOD school to finish up my training and become an EOD technician. After that, I was stationed at EOD Mobile Unit 8 in Sigonella, Sicily. I did a little over three years in Sigonella.

INTERVIEWER: You did some training with the Special Warfare Development Group?

EN1 ANDREWS: Yes, exactly. From there, I was TAD'd to Training Unit 2 for the better part of the year and then transferred to a shore detachment based out of Mobile Unit 2. It's Detachment Earl in New Jersey. Within the last year, in March, actually, I was transferred to Naval Special Clearance Team One here in San Diego.

INTERVIEWER: You've been here less than a year, then?

EN1 ANDREWS: Yes.

INTERVIEWER: How long were you on board before you went to Iraq?

EN1 ANDREWS: I was stationed, or I got on board, and within a week was transferred to Iraq.

INTERVIEWER: That's amazing. Did you expect that when you came here?

EN1 ANDREWS: It was actually up and down. I had spoken to people and the guys on my last team were trying to get me out here, be it the chance I could go and be a part of Operation Iraqi Freedom. The last word that I got when I left my private documents at Earl was that I wouldn't be going, so I came here with the notion that I would be staying behind. Then, once I got here it was put out that they needed operators out there, so they tried to get me out there as soon as possible. Within a week I was transferred out there.

INTERVIEWER: The rest of the unit was already out there?

EN1 ANDREWS: Yes. Actually, when I first got here they were basically loading up and leaving.

INTERVIEWER: You weren't very much behind them when you got over there.

EN1 ANDREWS: No. They were literally about a week ahead of me.

INTERVIEWER: You were doing the Unmanned Underwater Vehicles?

EN1 ANDREWS: That's correct.

INTERVIEWER: How did you get assigned to that?

EN1 ANDREWS: I don't know if it was a request or anything. I didn't know much about them but I had called forward to find out where I would be stationed within the command. They said that was the platoon that I was going to. I tried to find out as much as I could before I got here, as far as what they did, who was in the platoon and things of that nature.

INTERVIEWER: You are like a diver in the platoon?

EN1 ANDREWS: Yes. That's right.

INTERVIEWER: I was wondering, because you are an engineman. You'd think that they would have an electronics technician to run the Unmanned Underwater Vehicle (UUV).

EN1 ANDREWS: Actually, they do. They do have two or three individuals who do a lot of the programming. But it's one of those things with which we, as operators, try to learn and work as much as possible with, as well as the programming side of the house. We go out and launch the vehicles, depending on where they need us and what type of situation and so on and so forth.

INTERVIEWER: After the vehicle goes out and maps an area and scans contacts, you go out and verify them?

EN1 ANDREWS: Actually, we go out and set up a grid. We lay transponders that the UUV can actually use as beacons to find out where it is in relation to this grid that we want to program in. We lay out that grid and then we launch the UUV, but prior to that, before we even lay this grid, we program all information based on maps and the area that we want to cover and so on and so forth. We program in how much coverage we want, how much of a side scan we need and how much yardage we want on a scan. We send that out and program it all in the night before and set up everything the night before, like you would for a regular dive operation. The following day, we go out, lay the grid, launch the UUV, let it do its thing, come back, retrieve the UUV, download the information afterward and find out what it did scan and whether there were contacts or anything like that.

INTERVIEWER: How many guys are on a UUV platoon?

EN1 ANDREWS: When I got on board, there were eight or ten. They are trying to get it up to 17, I believe.

INTERVIEWER: Are they a mix of reconnaissance Marines and SEALs and EOD people?

EN1 ANDREWS: Yes. They have all three areas and I think we had a couple of sonar technicians, as well.

INTERVIEWER: Doctrinally, what do the divers do?

EN1 ANDREWS: We're the ones who are actually going out and doing the physical work, whereas the fleet technicians are going to stay back, and I don't know if you would say we go 'into harm's way.' We check out any kinds of problems, do the download afterward and the post-mission analysis. We set up a disk with all the information that we gathered from the UUV.

INTERVIEWER: Then, you dive on the context that the UUV generates?

EN1 ANDREWS: We do not. We pass that along up the chain to the doghouse and to the top. Then, they can either choose to decipher that information further with the mammals, if they want them to require any of these contacts or give them to what was, at one time, just a single dive

platoon. The dive platoon could go and dive on the contacts afterward if they felt it was a strong enough contact that the UUV picked up.

INTERVIEWER: What's the doghouse?

EN1 ANDREWS: It's similar to the top, I guess. It would just be the head shed through which they would disseminate all the information.

INTERVIEWER: How much diving did you do?

EN1 ANDREWS: I did not do any diving while I was in Iraq. It was strictly just surface operations, working with the UUV.

INTERVIEWER: The UUV really earned its pay over there, huh?

EN1 ANDREWS: Yes, it did. It got a lot of attention, from what I understand, from a lot of higher-up admirals and so on and so forth. They took a particular interest in it, from what I understand.

INTERVIEWER: How important do you think the UUV was to the success of the clearance team's mission?

EN1 ANDREWS: I think that it played a major role in that it allowed for much quicker area coverage. It allowed us to see exactly what was going on with the currents and what type of bottom type we had. It also gave temperature readings, bathymetry, and everything along those lines so that we knew exactly what was going on.

Then, if there were any questions, we could run the UUV again and make sure, without having to put any of the mammals in if we so chose, or if they didn't feel that the mammals were needed for that. It cut down the search time from possibly weeks to a matter of days, as far as the area of recovery we had to do.

INTERVIEWER: That was important, right, because you had 72 hours to clear the port so that humanitarian aid could arrive?

EN1 ANDREWS: That's exactly correct.

INTERVIEWER: Were you able to get that done?

EN1 ANDREWS: Yes.

INTERVIEWER: The UUV cleared most of Umqasr?

EN1 ANDREWS: Yes, it definitely did.

INTERVIEWER: What sort of contacts did they find?

EN1 ANDREWS: The great majority of them was made up of grain bags, tires, or some other junk down there. I believe they did have a couple of sub-surface wrecks. They managed to get good Latin long on for future references.

INTERVIEWER: In the end, they were able to establish to a very high degree of confidence that the port had not been mined?

EN1 ANDREWS: Yes. That's Correct

INTERVIEWER: After you finished at Umm Qasr, what did you do?

EN1 ANDREWS: When the old port was done, half the team split off to clear up the new port and the other half of the team had a mission to go find a downed F-18 up in the lake area, closer to Baghdad.

INTERVIEWER: Where were you?

EN1 ANDREWS: I was one of the individuals who split and went to the new port to clear it.

INTERVIEWER: What did you find up there?

EN1 ANDREWS: We found more of the same, like a lot of tires grain bags. It was a much smaller port. We managed to do that in two separate missions, two days' worth of work, in about three hours for each mission during the day.

INTERVIEWER: That's pretty impressive. That port was also used for humanitarian material?

EN1 ANDREWS: It might have been. I don't know that it was, but they were waiting on it as much as the old port. I'm sure that they probably moved ships in there afterward, after we were done with it. They never really told us exactly for what it was going to be used, but they said that it needed to be cleared, just in case.

INTERVIEWER: With the old port, you guys were under a lot of pressure to get finished quickly?

EN1 ANDREWS: Yes.

INTERVIEWER: What about the lake job? How did that turn out?

EN1 ANDREWS: It turned out they had a large area to cover. They broke it off into different sections. They had a downed pilot. They had the exact location of the F-18. The pilot had been ejected from the plane and it was the job of the other half of the UUV team to go find that pilot.

They just started breaking it up symmetrically. I think it was the third day they found the body, but it had decomposed. There were gases in the body and it buoyed up and they managed to find it just from a visual sighting. Nonetheless, we were up there using that and I guess it got a lot of attention. A lot of people did not know that we were able to do that for lakes and things of that nature.

INTERVIEWER: That's kind of a grim job, though.

EN1 ANDREWS: Unfortunately, yes it is.

INTERVIEWER: How long were you over there?

EN1 ANDREWS: From the get-go until the time we came back, it was three months, I believe.

INTERVIEWER: That's pretty exciting, to show up on your first week and get sent off to war, huh?

EN1 ANDREWS: It was definitely a trial by fire, you know. But I wouldn't change it. I definitely enjoyed it. I was welcomed with open arms, and we had a good bunch of guys that I worked with on the UUVs. The rest of the crew just seemed to be an outstanding bunch of guys.

INTERVIEWER: Now you're with the dive platoon?

EN1 ANDREWS: Yes.

INTERVIEWER: How do you like that?

EN1 ANDREWS: It's different. It isn't better or worse. It's just a different job. I like it as well as the other stuff. I definitely enjoy it.

INTERVIEWER: Do you like diving in the Viper?

EN1 ANDREWS: I do. I just went through a Viper class when I came back here, just to get certified for that. I have been fortunate enough to dive in a number of different rigs throughout

my travels in EOD to my various commands. I like it. It's a good rig. There's both a plus and a minus side to it. But all in all, it's a decent rig to dive. I have no major complaints about it.

INTERVIEWER: Having gone and seen the UUV in action and all the attention you got, do you think UUVs will eventually replace divers?

EN1 ANDREWS: I think that they will. I think there will come a time, and that's the Navy's objective, from what I understand, to get the human factor out of that loop so that they don't have to do that.

INTERVIEWER: Do you mean for mine searches?

EN1 ANDREWS: That's exactly right. From what I've seen in the short time that I've been here, just being privy to the first of many upcoming things, it definitely seems to be a very exciting field. A lot of advancements are coming out and technology is just growing by leaps and bounds. It's going to be interesting to see what happens here within the next few years, definitely, as far as UUVs are concerned.

INTERVIEWER: Hey, is there anything else we didn't discuss that we ought to?

EN1 ANDREWS: Off the top of my head there's nothing I can think of.

INTERVIEWER: Well, thank you very much.

IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS**

**Interview of  
PROF. DAVID ELLIOTT, O.B.E.  
Shell Professorial Research Fellow  
Robens Institute of Health and Safety  
University of Surrey**

## PROCEEDINGS

INTERVIEWER: Dr. Elliott, tell us something about your background. Start back when you were a youngster and tell us where you were raised, where you went to school and so forth and then bring it forward until you got into the diving business.

DR. ELLIOTT: Wow. That's a big jump, isn't it? My early childhood was before the Second World War, about which I remember quite a bit. In particular, I remember that just before D-Day, my father walked me along the cliffs by the English Channel, because he was in the military, and that permitted me into the no-go zone. He asked, "What do you want to do when you grow up, son?" As he was in the Army, I said, "I want to join the Navy. I think I'd like to be the doctor of an aircraft carrier."

Well, I managed to do most of that except I never actually became the doctor of an aircraft carrier. I had that thought in the back of my mind, and that must have been at the age of nine or ten. I came out the other end a few years later, qualified as a young physician.

We then had national service to do in the British military. My father said to me, "Son, I can get you a job as a regimental medical officer for my old regiment." I said, "Dad, rather than do a year and a half with that regiment, I've signed on for three years in the Navy because it's a better deal." You can see that I was an absolutely normal child rebelling against his parents. In fact, what happened thereafter was that I had to do a three-year short service commission in the Navy, which was, after doing intensive house jobs and all the rest of it in the civil sector, an interesting period. The level of medicine required, of course, like most military peacetime jobs, was ever smaller. You were really

on board a ship. I was on board a ship in the Far East. You were there like an umbrella, just in case something went wrong.

My entire three years in the Navy, plus the large tax-free lump sum I got at the end, were justified by just one incident. I looked at a particular patient and told the commanding officer that we did not have to take the ship, which had been ten days steaming altogether, back to Singapore. That saved the ship enough money, as it was a hydrography ship, to totally cover my salary for the three years. The umbrella was used, but the umbrella was only used for about five minutes of my three-year commission.

That's me in a nutshell. I then left the Navy along with everybody else and went into research at University of Oxford. There I was in a wonderful department that had, incidentally, a very strong history of work with the Navy during the war. That was where they did all the ergonomics and thermal work with a man working inside gun turrets and things like that. It was a fantastic department. The great joy of Oxford in those days was that you had a pass into the scientific part of the Bodleian Library and could go down to the stacks yourself and thumb through. One learned a whole lot. One learned that you could find a report on a particular experiment written by the same names, but the names were in a different order, and they had the same facts but came to conflicting conclusions. That is the purpose of learning research. It doesn't matter what subject.

At that particular stage, I realized that the base of the pyramid for promotion in the academic world, and medicine in the U.K., was spreading wider and wider, and the chances of actually moving on financially were pretty poor, even in those days. The opportunity to combine research with a career in the Navy was again one of those serendipitous opportunities. You just have to grab it before it goes. I grabbed it, and there

I was. I was sent straight down to the RNPL. That's not quite true, actually. They did pay for my last year at Oxford just to get my thesis written before I came back, to be honest.

INTERVIEWER: That was at St. Bart's?

DR. ELLIOTT: No. It was at Wilfred Le Gros Clark at Oxford University. I did research into the growth of collagen, which was a totally useless and esoteric subject. I thought nothing more of it. I published some papers and proceedings at the Royal Society. The papers all sounded very clever until many years later. Brian Hills, who everybody knows is a very good decompression modeler and theorist, once said to that he was working on the kangaroo rat's tail tendon as a model tissue for decompression studies. He said the great joy of doing that was that it was a tissue in which the modelers of elasticity were known. There was a paper by my namesake that was relevant. He pulled out the paper I had written for *Biological Review* on the growth of collagen strength. Unwittingly, I'd made my first contribution to diving literature, so that was a start. How about that?

INTERVIEWER: Let's go back even further. You were born in 1931, 1930?

DR. ELLIOTT: I was born in 1932.

INTERVIEWER: Where?

DR. ELLIOTT: I was born in London. I went to school in Canterbury and had a very privileged time there. The school is actually going through its fourteen-hundredth anniversary next year. When you have a background like that, you realize how transient the activities of individuals are. Basically, I went from Canterbury and trained at St. Bart's Hospital in London, and that was a fantastic period of time. At the end of it, people like me had to go and do national service.

I was thinking of going in for obstetrics and using the anatomy and physiology to work toward surgery. But then, I got a phone call from a chum of mine who'd stayed in the Navy. I was just about finished with my doctorate of philosophy at that stage. He told me he'd been talking to the appointing officer within the Navy. They were looking for somebody who would come in and look after the naval medical branch's research program, and asked whether I was interested. The long and short of it was yes. It meant going back to the quality of life that I felt my family deserved and going into a research area, which had much more practical applications. It was actually general naval physiology.

My first acquaintance with underwater medicine would have been some lectures during which we probably fell asleep. They were on oxygen toxicity, nitrogen narcosis, decompression and so forth and given by the gurus of the time, people like Val Hempelman and so on. They were really good people. That would have been 1958. Nothing very exciting was happening. As the years went by, of course, things began to gather momentum. I must say that at that stage, diving medicine was part of the syllabus, like aviation medicine and submarine medicine, and it was just one of the things one learned.

Again, this is another irrelevant little piece for your mosaic, but I think it may be of interest. The lifestyle of a naval medical officer was such that in those days, which were the late 1950s, and this was actually at the naval hospital in Plymouth, one would roll in at about nine o'clock, in uniform, into the office of the senior medical officer, surgery, the surgeon captain. You'd stand there, talk to him for five minutes, and ask whether there were any admissions last night and so forth. It was usually absolutely

nothing, and then one would retire to one's wards. You'd have coffee with all the sisters in your own wards and your colleague's ward down the corridor and so on. Then, at about half-past eleven, you slowly wandered back to the mess because the bar opened at noon.

INTERVIEWER: If you can, pick out two or three people who influenced you to get into the diving field and what impact they had on your decisions.

DR. ELLIOTT: One person who was very influential with me was Johnny Rawlins. The thing about John is that a lot of people think of him in a certain way. There was a paper written on escaping from an upside-down, underwater aircraft. What you don't realize is that he was actually the subject in that airplane.

The first thing I did once I finished my Ph.D. was to go down to the Naval Physiological Laboratory in Alverstoke. Eric McKay, who did a lot of work with the HMS *Reclaim*, was one of the doctors there. When I joined in 1965, approximately, he went on to another job and his number two, Peter Barnard, who was a couple years in the navy and senior to me, became my boss. I took the junior job. As a diving medical officer in those days, I went off and did the clearance diving course and all those sorts of things. We were at the forefront, which would sound grand if you judged that by today's standards. We were at the front line of what was a very small organization. We had a diving team to work with. We had the RNPL, which was doing all the physiological research, to work with. We were two uniformed doctors in a civilian research unit that was using naval divers to do the work. There was nothing else.

There was really no recreational diving in the U.K., other than a few mad enthusiasts. There were no other operational chambers in the U.K. There were one or two

in dockyards that could be called on if needed, but nobody ever wanted to use them. There were perhaps one or two cases of civilian decompression sickness each year in the whole country, and there'd be people diving in dockyards and things like that. They weren't recreational divers.

I joined RNPL in 1964, when I got my Ph.D. I became the junior doctor there alongside Peter Barnard. We worked together for three or four years. 1965 was when the submarine escape trials were being done. I can't remember if it was before or after that, but during the same summer, Peter Barnard and I and the whole of the HMS *Reclaim* went to Le Lavandou on the south coast of France. We were based at Toulon Navy Base and started to do bounce dives on sea trials, having already cleared them.

The laboratory work had been going on for years before I joined. I get no credit for the research. I was just part of the medical cover. But we then found that having the medical cover was quite a responsibility. Those dives were being done with the ship in deep water off the Iles d'Hyeres, which are not far from Toulon. They were important because we learned a lot of lessons. The cases themselves have been written up elsewhere, but just for marking the milestones, I think two are worth mentioning because they do affect the policy of deep bounce diving, recompression and those sorts of things.

I think the first one to mention was that somebody had made one of those deep dives. Bear in mind that in the British navy, for academic purity, the dive was made with no single atmosphere of air in the chamber to start with. The chamber was cleared out and filled with oxy-helium, so there was no nitrogen loading of any significance in the chamber. On board the ship, they would use an oro-nasal mask as they did their compression.

They then went down to depth in the bell to do their swims, which were quite brief. The maximum duration was an hour, and a lot of the dives were only thirty minutes. They came back into the bell, locked into the bell, brought it back to the surface, locked into the deck chamber, and underwent a decompression, which would last, as far as I can remember, for maybe a couple of days or so.

There was no great sort of structural engineering problem except that our deck chamber had a maximum depth of 300 feet. Any decompression deeper than 300 feet had to be done in the bell in the water. Our particular protocol was that the people breathed oxy-helium all the way to the surface. Upon reaching the surface, the door would be opened and at atmospheric pressure, they'd switch to air.

We'd already worked out that when a person got a bend deeper than 165 feet, the conventional treatment tables were absolutely useless because they didn't go that deep. Mickey Goodman's table was just coming in at that stage. We had very conveniently gotten these divers to the surface and had established a new routine for treating people who surfaced with bends after helium exposure. The reason I emphasize that is because there was some confusion between the British and the American navies, who have a very close working relationship. It is similar in the United States. They are not dives quite as deep, but there is a switch from helium to air quite deep. Therefore, because the divers had already made the switch and decompressed an hour or two or longer on air, they had no problems at all when they recompressed any bent diver on air and did not see why we insisted on using helium. That sort of concluded that phase. It was a setback, but we carried on diving.

The focus of our lives was propelling the deep-diving research. Dr. Taylor was then the superintendent of RNPL. We were producing tables, or trying to produce safe tables, to do dives at 450 feet, 600 feet for durations of thirty to sixty minutes and an 800-foot dive for twenty minutes. That was pretty much our work in that field.

At the same time, quite independently but in the same lab, the SCOSER Committee was responsible for improving submarine escape. A program was already well underway. The primary movers were Dr. Cam Wright and some people at the submarine escape tank, like Jimmy Hamlin, who was the command escape officer, his deputy, Matthew Todd, and an engineer whose name I can't remember. Cam Wright and others worked on his work to show that by making a buoyant ascent, the exhalation of gas was sufficient to keep the carbon dioxide below the threshold for having to take a deep breath in, providing one ascended at a reasonable rate. The trials were done by human volunteers at RNPL in tanks of water in the chamber from about 300 feet. The whole business of submarine escape that the British navy had worked out from tragic precedent assumed that surface people could come and rescue a submarine. First of all, they had great difficulty in finding it. Second, when they got there, there wasn't very much they could do except pick up the survivors. The British navy worked it out that as long as people got out of the submarine themselves, provided they had adequate thermal protection at the surface, it would be the primary method of escape.

This is basically well known physiology, so I won't waste much time on it. Compartment escape was limited by the fact that the compression was very slow. Therefore, one could only make shallow escapes without lost people getting decompression sickness. One tried to make the compartment smaller, and this idea had

been around for a long time, since some of the early escape hatches in the 1930s were pretty small units that the submariners would get into. But the idea was to try to make it so that the person who was essentially waiting at one atmosphere to come to the surface without decompression sickness. The slight overpressure that occurs in sunken submarines was not really a matter that we concerned ourselves with too much at that particular state of the research. Subsequently, it's become important for both escape and for rescue. They tried to reduce the exposure so that by rapidly compressing somebody to a great depth, they would be able to come to the surface without decompression sickness.

Now that entire research is well written, and the program was essentially a thirty-second compression. With the upshot trials in which I was involved in 1965, it was a thirty-second compression with about five or so seconds at maximum depth and an ascent at between eight and ten feet per second. It took about fifty seconds to get to the surface. That was how men got out of a submarine at 500 feet. Matthew Todd was the first.

Because we didn't have any thermal heating in those days for helium diving, they put hot water bottles inside their dry suits in secret because they didn't want anybody else to know. They'd be thought of as sissies. They had a couple of hot water bottles quietly locked in without me noticing, which, of course, I think was very good, indeed. We unlocked the diving bell, dropped it over the side into 300 feet of water, opened the bottom door and then started slowly to lower it.

We didn't even have a helium unscrambler. In the bell, you could hear topside, but if they spoke, it was in a helium voice. When an individual had a problem with staggers, as did happen, you'd be asking, "Are you better? Are you worse? Are you the same?" To those questions, the responses would be thumbs up, thumbs down, or the horizontal okay.

That was the only way we could communicate with the people in the bell. There were lots and lots of very primitive things.

What really got us was the fact that we could not recompress deeper than 300 feet. Even at 300 feet, we had difficulty locking the bell onto the deck chamber. We had many other reservations about it. Peter Barnard and I advised the captain, "We cannot guarantee that we are going to be able to solve it if you have a problem at these depths."

Although the navy wanted to put a new chamber into the *Reclaim* during the coming years, you can well understand the bureaucracy that went on. We were offered a free chamber by industry to fit into the HMS *Reclaim*. It was the right size. The only difference was that it had something like a 600 or 800-foot capability, as opposed to the 300-foot capability of our present one. The Navy rejected it on the grounds that it didn't have any STANAG number. A STANAG is the standardization within the North Atlantic Treaty Organization and the numbers are assigned to each part so that there is an adequate supply of spares in time of war. You could think of nothing less relevant. There we had the opportunity of a deep diving system on the HMS *Reclaim*, and we could have continued our program. It was killed in the first instance because Peter and I said, "This is not safe," and second, because the bureaucrats wouldn't replace the unsafe equipment. That was the end of the navy's deep diving program. We had a few convulsive efforts trying to get it started again.

INTERVIEWER: What year was that?

DR. ELLIOTT: That would have been 1965 to 1966. We continued expecting the HMS *Reclaim* to be ready. We continued the development program in the RNPL. At that time, DiveCon came in and dived with us, using our dry chamber. Al Behnke was actually the

advisor to DiveCon, and I know that his tables switched from helium to air at about a hundred feet.

We decided that ethically, in order to dive as deep as, shall we say, 600 feet, the deck chamber had to go to 600 feet. You couldn't rely on a 300-foot chamber. That essentially meant that was the end of the diving trial. That, in fact, proved to be the end of the Royal Navy's deep bounce diving. In fact, as far as the development of diving was concerned, that research was really quite important to you guys, by which I mean George Bond and the U.S. Navy. With your own participation with Ed Link and so forth, you were much more focused on saturation diving, probably habitat diving at that particular stage. Ours was based on a submersible bell going down, doing something and coming back.

In the RNPL, we had two things happening. We had the development of submarine escape, and all the hard work for that had pretty well been done. Jimmy Hamlin and Matthew Todd were the command escape officers. My involvement was non-research. It was purely the medical officer duties of standing by and catching any problems. But there are a lot of very important experiences, like blowing Matthew Todd down to 300 feet in a couple of seconds accidentally and that sort of thing. Many things were developed again by serendipity in submarine escape.

At that time, the U.S. Navy was actually not doing saturation work. They were looking at some fairly deep bounce for some particular reason. I don't know why. At that particular stage, the British navy approach to decompression was based on the bounce dive and we had a lot of experience with that. I think in the United States Navy, there were two other developments to which we were not a party. One was saturation diving up

to SeaLab. The other one was, of course, the minimal recompression tables of which we'd heard whisper developed by Mickey Goodman and Bob Workman. Bear in mind that the experiences of people like Peter and me were of decompression sickness with an abrupt onset that we had the ability to recompress within a minute or two and completely get rid of.

At that particular time, industry, for what it was worth, mostly in North African oil, was doing hardhat bounce diving at 400 to 500 feet. During that period, we had various cases, like paradoxical recompression. We had to learn in water to 455 feet in order to clear his vestibular bends. We had a lot of good clinical academic experience, all of which has been written up elsewhere. I think it also marked the end of the navy's deep diving program because of the problems we had imposed by the limitations of the equipment available to us. That was in the days when divers expected to not get cold.

We still did quite a lot of bounce diving, and there was some operational bounce diving, too. For instance, we concluded that if we got a helium bend, it was preferable to recompress in helium. We decided if you were going to do a deep dive, the chamber must go to the maximum depth of that dive so that you don't have to put people back for recompression in the water. The third point was just a very interesting one. Those, to me, were all the highlights. We had lots of ordinary bends and things like that, but these were things that really sort of struck one firmly between the eyes.

The other dive was on board the same ship, but it was an operational dive. We recovered some prototype torpedoes from Loch Fine from about 450 feet. Anyway, the important thing was that the divers would come back into the bell for lock-on because the decompression stops were fairly short on that particular dive. There wasn't time to lock

them on until they had reached 120 feet. At 120 feet, which was where they switched from 10/90 to 20/80, they were then being locked on. I happened to be watching the closed-circuit television. There was suddenly a noise from the television set that looked down inside the bell. I could see two divers collapsing to the floor, unconscious. They didn't have any BIBS in their mouths, but they should have. They were breathing chamber atmosphere. At that particular moment, we realized there could be a crisis. I went up the stairs and asked the diving officer if we could actually do something about this. You just made those decisions very quickly. They may not have necessarily been the best decisions, and there may have been other ways to do things. But what we did worked, which was to immediately blow the chamber back from 120 feet, where this happened, to 300 feet using a new bank of gas.

The trouble with the bell was that it had an inwardly opening door, and we locked it on. Luckily, one of our divers, who later became a policeman, was a huge individual and was locked into the deck chamber. We blew him down to 300 feet. By sheer strength, he opened it.

We then discovered that those individuals had accidentally been put onto pure oxygen at 120 feet. It took us a few hours to work that out. What they had done was go into oxygen anesthesia with no fit or anything. We sort of scratched our heads about that.

But the consultant to the Navy was Bill Payton, professor of pharmacology at Oxford. He said, "Ah, yes. Well, you haven't read my paper, have you?" He'd actually published a paper on the narcotic effects of oxygen, and we had demonstrated it. Thereafter, the subsequent decompression was reasonable, but it did actually sound the death knell of the HMS *Reclaim* and the deep diving research, because we realized we

didn't have a decent system. I think that probably occurred in 1966 or 1967, a year or so after the other incidents. Al Behnke used the same routine that the U.S. Navy had been using. He actually switched the divers from oxy-helium to air at quite a deep depth. Every time that happened with us, the divers got symptoms just after the switch. We had a discussion with Al and made the switch to air at a more shallow depth and stretched the stops a bit, and I think that worked out okay. But it was a very interesting phase, and that, again, lasted several months. You can well imagine that with all the horrendous bends and so forth we were getting at that time, we were getting a lot of experience.

INTERVIEWER: The dives with DiveCon were being done at the AEDU or the RNPL?

DR. ELLIOTT: They were being done at the RNPL and were dry chamber dives, testing Behnke's schedules for work in the oil industry.

INTERVIEWER: How deep were they?

DR. ELLIOTT: They could have been 600 feet for an hour of bottom time. The EDU was opening up for SeaLab III, and it was interested in doing some deep excursions. I think I was invited because people knew by then that I'd been in some crazy situations. Anyway, they very kindly paid for me to go out. On that occasion, I stayed with Will, whose surname I forget, but he was one of the EDU doctors. Then, as soon as the SeaLab crew came in, I shared a flat with Walt Mazzone, Paul Linaweaver, Mark Bradley and Jim Vorosmarti. The SeaLab team took the chamber deeper than 1,000 feet for the first time in the history of the U.S. Navy, and that was really quite a remarkable experience. At about that time, Johnny Rawlins was the British navy exchange officer with the Bethesda team. I was then appointed to replace him, which I did around about early 1970, and had three years out at the Navy Medical Research Institute.

INTERVIEWER: One of the missing links is the interaction between the U.S. Navy and the British navy. You've mentioned that a couple of times, but one of the things I want to make sure we discuss, because the Royal Navy influenced it greatly, is what happened in the U.S. Navy and undersea technology in three specific areas: the closed circuit breathing apparatus, submarine escape, and basic deep diving.

DR. ELLIOTT: Well, I hope that is all true. My perspective is not quite as strong as that. Certainly, there's no doubt that there was a lot of collaboration between the two navies. We had the IEP B-12, the information exchange program, which was very useful because it meant we met every six months and compared notes. There's no doubt about it. The U.S. Navy was very helpful to us, as well. It was very much a healthy, two-way exchange.

When it comes to those specific items, let's take the closed-circuit breathing apparatus first. That makes me think of the breathing apparatus that was being developed for use with the Mark I diving system, rather than the Mark II diving system. I think that was almost post-SeaLab, actually. Divex in New Orleans was developing it under a U.S. Navy contract, but we were very much involved in that. I can remember driving to the Divex place a few times during our various visits.

That went on for a long time, and it was developing the bell-mounted scrubbing system of recirculation, so the closed circuit refers to a bell-mounted unit with a supply and return line hose to the diver. Unlike the commercial stuff that Krasberg and others developed later, the gas was not returned all the way to the surface, as far as I recollect. But that was very much an engineering project, so I didn't get too involved with that except that I'd go along for the drinks.

The U.S. Navy was very keen to make sure that we were able to continue to do such work when possible. That led to programs that lasted through into the 1970s in which we would do joint dives with the U.S. Navy. By that time, the U.S. Navy had moved, in fact, to Panama City. That was all part of this same continuing IEP, or information exchange program, and the MOU, or the memorandum of our understanding, which existed between the two countries. Through those did we freely exchange information on all sorts of things.

I was not concerned with breathing apparatus equipment development, which could well have been part of the entirety, but very much more concerned with the human aspects of the development of safe diving protocol. Because of the tragic fire at the EDU, the Experimental Diving Unit actually came, and I can't remember for how long, but certainly for months, and worked at the RNPL deep trials unit and did some deep dives. We got some very good experiences out of that.

I think our experience with deep diving was of great help to the U.S. Navy. At that stage, Bob Workman and Mickey Goodman had developed the protocol for shallow oxygen recompression of compressed air decompression sickness, and the mind-set of the EDU doctors was very much in favor of that. We were not that convinced because our experience was with deeper diving that required deeper recompression.

We were meeting in alternate countries every six months or so and exchanging a lot of information. I was confined to the medical and physiological staff really, so I think on equipment development, I'm not really the person to speak. It was very much teamwork. It was a great time to be in the field. I thoroughly enjoyed it. Do you want to backtrack to submarine escape?

INTERVIEWER: Oh, yes.

DR. ELLIOTT: I was on the 500-foot escape and could tell you a lot of tales about that, as well.

INTERVIEWER: You actually made that escape, didn't you?

DR. ELLIOTT: No. I've done it from 100 feet. I haven't done it from 500 feet. The general feeling is that as far as human ethics are concerned, we've gotten to the end of what we can do safely in submarine escape from a sub that is still at one atmosphere, because to do more experiments might expose the subjects to decompression sickness. What it meant was that if a submarine was stranded perhaps as deep as 800 or 900 feet, the persons on board would be able to make an independent escape without any surface support, and a significantly large proportion of them, if not all, would make it successfully. It's just that it's unethical to do the research. I didn't get involved with submarine rescue. I certainly went to have a look at the deep sea rescue vehicle (DSRV). Submarine escape, to us, was solved. I think that was only a year or two ago. I know the U.S. submarines didn't adopt it as a secondary method of escape, but the actual configuration of the escape tower was quite awkward in some of our nuclear submarines, as well, you know.

I don't know who the scientist responsible for this idea came from or who he was, but they had a submarine escape suit which was, of course, a bit like the Michelin Man. It was this quilted, air-inflated, double-skinned suit that certainly provided a lot of thermal protection. The current system, of course, is to get into a life raft, because that is even better, thermally.

I think that it's worth mentioning that the double skin has been taken even further and has been made into a triple skin, but I don't think that the British navy has adopted it. It's become part of the offshore industry's survival at sea, particularly if people are escaping from a sinking helicopter, and ocean racers have also adopted it. If you have a triple skin, you don't get any cold patches because where there's a weld between two of the skins, the third skin is separate and full of gas. Whoever it was actually demonstrated that these suits are good for 24 hours of immersion in really cold water and probably all right for much longer.

Later, in the Falklands, we had a bit of a problem with a number of Marines going down with some of the helicopters. The idea of providing passengers with means of escaping from a helicopter was important to us in the oil industry because we have cooks and bottle-washers who go off there and their lives are as valuable as anybody else's.

The concept of an air pocket is that you re-breathe from your rubber bag. Underwater duration would prolong it from the normal no-stop time of less than 25 seconds, which is not enough time to get everybody out of a helicopter, to about 45 to 55 seconds, which is long enough. All the trials were conducted in dunker training units in cold water, and we know that it works. This was a development that I think was worthwhile, and it basically came from the submarine escape ideas. In fact, one is limited by carbon dioxide buildup. There is a bit of oxygen deprivation, as well, but it is not significant because, of course, with the new air pockets, there are little cylinders so you can actually top the things up and last a bit longer still. Although that may or may not have some potential military application, and it's for the SEAL team crowd to answer that question, nevertheless, it's another good example of what was started by the original

collaboration between the two navies in the 1960s. I think that sort of puts all the submarine escape stuff together and into context.

INTERVIEWER: Let's go to your time with the Naval Medical Research Institute as an exchange officer. Tell us some about what you did there.

DR. ELLIOTT: Oh, that was fabulous. That was the best appointment I ever had in the Navy. Bearing in mind that while I was supposed to be doing physiological and animal research at RNPL, it was very difficult to get it properly funded. The nice thing was that I went to NMRI and the commanding officer, Tor Richter, whom I'd already met at various meetings. He and his wife were very supportive of us. I took over from Johnny Rawlings.

INTERVIEWER: That was at the beginning of the SeaLab III program, which preempted the EDU, which was why the EDU divers went to England.

DR. ELLIOTT: That could well be.

INTERVIEWER: I was at the EDU.

DR. ELLIOTT: At that stage, you were working with George Bond, I think.

It was great to see the ways that Walt Mazzone maintained the morale of his group and did it in subtle ways, like being the chef for everybody and cooking the meal. It may have been instinctive, but it was wonderful leadership.

INTERVIEWER: How about the Undersea Medical Society? It was founded in the United States.

DR. ELLIOTT: Yes. I did not get to the first meeting because we were very short of travel funds. What happened was that whoever had the most clout and wanted to go

would get there. Peter got there one year, and the year that I wanted to go, Stanley Miles went and so forth and so on.

INTERVIEWER: Were those the underwater physiology symposia that you are talking about?

DR. ELLIOTT: They were the underwater physiology symposia, yes.

INTERVIEWER: They were in 1967 and 1970.

DR. ELLIOTT: That's right.

## **“ONE MORE STORY” BY EARL F. LAWRENCE**

I was born and raised on a farm in Missouri. My dad was as tough as nails, and that was the way he treated me. He would send me, at the age of nine, out on jobs that were tough for a grown man. I never said to him that I couldn't do it. I never could say that in front of him because he would have kicked me right in the butt! From a young age, he treated me as if I was a man. I learned the hard way and I learned the good way. I was raised on the farm and learned to take responsibility at a young age.

I joined the Navy in 1935, at age eighteen, and went to the Naval Training Station in Great Lakes, Illinois. I finished my training there and was transferred to a submarine tender, the USS *Holland*, which was stationed in San Diego. I wasn't aboard more than two weeks when a salvage ship belonging to the squadron was alongside for a ten-day repair. I would spend the evenings on the salvage ship talking to the divers about what they did for a living. I said, “Boy, that's for me!” In about two weeks, I got them to transfer me over to that salvage ship, where I started my diving career.

In 1937, I qualified as a second class diver and worked a lot of jobs on the ships around San Diego. Because I was the low man on the totem pole, I was given the dirty jobs, but I never turned them down. Those jobs taught me a lot about diving and taking on responsibility. I also learned that if you did not take responsibility for a job, you did not get blamed for a failure. For example, during this time, I had an experience with the skipper of a large harbor tugboat that had run aground near San Clemente. The harbor tug was hung up on the rocks for three days. All the skipper and I did was remove equipment from the tugboat and load it onto a small boat. I realized later that the skipper didn't want to even attempt to salvage the tugboat for fear of failure. If you did not take responsibility, then no one could fault you for not succeeding. At the end of three days, the tugboat broke up and slid off the rocks into deep water.

While on the salvage ship, I continued to dive and work on my other trade, a second class carpenter's mate. I was then sent to the Deep Sea Diving School, a first class diving school in Washington, D.C. It was a six-month school, where I learned underwater burning, welding, and ship fitting. While I was at the school, the submarine USS *Squalus* sank. The divers from the Navy Experimental Diving Unit, which was next door to the diving school, were all sent to salvage the submarine. It had sunk in 242 feet of water. At that time, the Navy didn't have a lot of divers. While the divers were gone on the *Squalus* job, our class was able to get a lot of diving experience in the Experimental Diving Unit. This was when helium and oxygen were being

developed for diving. Helium was taking the place of nitrogen. Our class members were used as guinea pigs to experiment with the use of the new gasses. We dove down 250 to 300 feet to see how we handled these experimental gasses. I completed the school in December of 1939 and became a first class diver, qualified for dives of three hundred feet. I then transferred back to the same salvage boat. We were the only salvage boat that had first class divers. Because of that, we had all the diving jobs along the west coast. I gained a lot of diving experience.

In April of 1940, I transferred back to the submarine tender, the *Holland*. I shipped out to Honolulu for about a year. Because of the concern about a possible attack by the Japanese, our ship was sent back to San Diego on rest and recovery. When we got back to San Diego, we received word that anyone getting paid off before the tenth of October could get out of the Navy. I had my six years of service and was due to get out of the Navy on the eighth. I made it by two days. I got paid off. I was out! Those who were in the Navy for longer terms had to stay for the duration of the war.

Before I left the Navy, I put in my resume at the Mare Island and Bremerton Naval Shipyards. The warrant carpenter and the divisional officer signed my resume for Mare Island, and it was sent in. The divisional officer, executive officer and captain signed the resume for Bremerton Naval Shipyard. Bremerton responded right away because I had 'diver' on my resume. They were looking for divers. I got out of the Navy, went home to Missouri to square everything away, bought a new car and drove to Bremerton, Washington.

As a side story to my trip from Missouri to Bremerton, I was traveling through western Nebraska when I picked up a kid who was hitchhiking to Seattle because he had just gotten a job with Boeing. We drove all day and night. We would pull over to the side of the road and sleep for a while, then continue. At a restaurant, we stopped for breakfast. The kid ordered a piece of pie and a glass of milk. The next time we stopped to eat, he ordered piece of pie and a glass of milk. Even for dinner, he ordered a piece of pie and a glass of milk! I said, "My God! Is that all you eat?" He responded, "You know, this is all I can get for 15 cents!" He was so broke that pie and milk was all he could afford. I took him all the way to Seattle. I then went to Bremerton and checked into the Navy Yard.

After I had worked in the Navy Yard for about a month, the labor board sent me down to the diving barge. The word was that the diving crew was going to see what I knew and then kick me out! Soon after I arrived, the crew got a job on an old steam tug that had knocked two of its rivets out below the water line after running into a pier and. It was close to quitting time, so the crew sent me home and headed out on the job. That didn't bother me, and I went back to my apartment on Washington Avenue. At about nine o'clock that night, I got a knock on the door. It was a sailor with the message that the crew wanted me down on the diving barge. When I got there, I saw the extent of the job and was told that George Bauer, the 'hotshot' diver, was trying to weld the holes created by the absent rivets. George was working on one hole. The boss told me to get

dressed, get down there and weld the second, or bottom, hole. When I got down there, I found that George hadn't welded the hole. He had actually made the hole larger. It was a mess. He had no idea how to weld underwater. I welded the bottom hole and came up topside. George was supposed to go back down and finish the first hole, but he never did. I ended up going down and welding the first hole the right way. My work on that old steam tugboat showed everybody that I knew what I was doing. It won me a place on the diving crew.

The crew had two members who had qualified as second class Navy divers at Keyport. They had completed three dives, two at fifty feet and one at ninety. Along with some diving they had done in the Navy Yard since qualifying, that was the extent of their training. George Bauer supposedly had diving experience outside of the Navy and was a topside welder, though had no idea how to weld underwater. Through the tugboat job, I proved that I could handle the underwater welding, so I ended up on the diving team permanently.

Shortly following the tugboat job, a plane went down in the Columbia River near Astoria, Oregon. It was a seaplane that had struck a log during take off. The impact of the log broke the plane right in half. There were four people in the plane, but only one survived. A little, redheaded lieutenant fell through the hole in the plane and was able to make it to the surface. They didn't have any divers in that area, so they called in the Navy Yard to recover the plane. Three of us from the diving crew went to the job. A Navy captain briefed us on what had happened. It turned out that the plane went down in fifty feet of water with four depth charges set to go off at fifty feet. The depth charges were still on the plane, hanging on the wing. If any of the depth charges were hit or dropped below fifty feet, they were likely to explode. Due to the danger of the job, the captain asked if we still wanted to dive. I said, "Heck, I'll dive down there. If the thing blows up, it's going to blow you up topside, too." The captain said, "Yeah, but we aren't going to be here. We're going to put you out on the tender, in a small boat, and you're going to do the diving while we circle around and watch what happens!" I said, "Heck, I'll go!" The captain told me not to go into the plane. He said, "Don't go inside. The men are in there and we don't want them disturbed." I made my dive and found the plane completely broken in two, split right about where the men would have been sitting. The plane was resting as described, but the tail had broken off from the main portion. I swam inside of the plane and discovered that there were no bodies inside. Meanwhile, the topside crew came out with a small tugboat and wire, which I used to hook to the tow pendant on the seaplane. When I got topside and climbed into the small tugboat, they started towing the plane to the beach. An ambulance came roaring down toward us as we got close to the beach. I asked, "What is the ambulance for?" The topside crew responded, "It's for the bodies in the plane." I said, "There aren't any bodies in there. I went into the plane and took a look while I was down there." They just blew their tops when they heard that! The plane was pulled up onto the shore. Of course, there were no bodies inside. They were never recovered. That was the first time that I had been called for a job because of a lack of qualified divers. It was my first job independent of the Navy Yard. I had been through a six-

month diving school and was qualified as a first class diver. I already had the qualifications and more experience than those so-called 'hotshot' divers did.

## **Burning and Welding**

I started taking a topside welding class at night school at the old Washington School in the yard. After attending the class for some time, I decided to set up an underwater practice stage for burning and welding. I rigged a stage underneath a pier in the Navy Yard, about ten feet off the bottom in nice, clear water. I built a table on the stage, just like at the topside welding school, with a place to sit and practice underwater welding and burning. I got tons of scrap metal from the ship fitter's shop and experimented with burning and welding for hours at a time. Through this experimenting, I built an underwater torch. The development of the torch brought me recognition in the newspaper and an award of \$150 from the Navy for such a beneficial suggestion.

The yard set up a schedule for the divers to practice welding one day a week. The other divers were too lazy to take to practice, so I wound up taking their allotted time and practiced burning all day. I became very efficient, using the welding tool that I had developed. The shipyard had a topside welding school at which participants were required to take welding tests. I was able to get all the test materials for the school and practiced those tests, underwater. I took my underwater welding pieces to the topside school and had them inspect my work. I passed all the required welding school exams with my underwater welding.

Word of my underwater welding abilities got around the shipyard and to Washington D. C., as well. The shipyard sent information to Washington about the underwater welding I had accomplished. I guess that the Navy Department didn't like my welding developments and to show us how welding should be done, it sent Lieutenant Norwood. Before he got to the shipyard, a box was delivered marked, 'Do not open until the arrival of Lieutenant Norwood.' When Lieutenant Norwood showed up, he opened his box, which held his burning equipment. He was there to show us how to use his equipment. We went down to the underwater stage and watched him burn for a while. We went back up topside and he asked me what I thought. I said, "I think you don't even know how to bum with your own equipment!" He got quite hostile. I invited him to go back down, where I proceeded to use his own equipment and just bum like crazy! The lieutenant stood there dumbfounded. He couldn't believe what was happening.

Our burning and welding program was quite successful. The shipyard kept sending material back to the Experimental Diving Unit in Washington D. C. I took a two-foot long, 18-inch wide plate and burned it across for a couple of inches. Then, I burned one piece all the way off. I used a straight edge and burned notch to show how the burn went neatly through both sides. Apparently, they finally believed that I could burn when they received the plate in Washington

D. C. They took pictures of it and used it in the underwater welding section of the Navy's new diving manual. It was a real compliment to me to have my work recognized in that way.

I began training sailors from ships coming into the shipyard. The ships would send six to eight sailors to the diving barge for six weeks' of burning and welding training. The program went through the apprentice school of the shipyard, which handled the qualifying paperwork for the sailors that completed the program successfully. I trained over 250 Navy divers and 24 Army engineers during the beginning of the program.

The Army sent a Lieutenant with his crew to Bremerton to go through the program. That unit of twenty-four divers later went overseas and worked on salvaging ships that had sunk in the English Channel. I was very pleased to hear from that group of Army divers through notes and Christmas cards. They wound up doing more diving across the English Channel than the sailors did! In 1946, I received permission to go through the diving school in New York City at Pier 88. The school was based around the USS *Normandy*, which had sunk right next to the pier after catching fire while tied up. The Fire Department responded by shooting volumes of water into the ship, attempting to put out the fire. As a result, the ship sank. During the six-week diving school, the divers, including me, were to learn how to burn and weld. It turned out that I knew more about welding and burning and ended up teaching them how to bum! I vividly recall the muddy, muddy Hudson River and dropping down into that mud, which came up to my knees!

### ***Diamond Knot Cargo***

A ship called the *Diamond Knot* was returning from Alaska with three-quarters of the season's salmon catch on board. It was about fifteen miles offshore from Port Angeles in the fog when another ship ran into the middle it and knocked a big hole in the side. The two ships were wedged together for hours. While wedged, the second ship tried to push the *Diamond Knot* closer to the shore until its captain thought he was about to run aground. As he backed out, the *Diamond Knot* took on water and sank. It sank in 136 feet of water with all the canned salmon on board.

A guy named Martinoni from a San Francisco insurance company got the job of salvaging the ship and its cargo. The cargo was insured for about four million dollars. Martinoni was able to secure topside equipment from Foss Launch and Tug Company but had trouble getting local divers. He ended up hiring divers from Portland and San Francisco. They had been working on the project for six weeks when Martinoni came into the shipyard for equipment and information. It turned out that he was an admiral in the Naval Reserves, so he was given permission to borrow my burning equipment for his job. Commander Price, in the shipyard production office, had a meeting with Martinoni and asked me to attend. Martinoni explained how he wanted to bum holes in the sides of the cargo holds and run a twelve inch siphon air lift to bring up the cans and dump them on a barge. The plan was to take the salmon to Seattle and Everett to re-can them. It

was 1947 and there was a shortage of food after the war. Martinoni complained that he was getting nowhere with the group of divers he hired for the job. Commander Price responded, "You know, the only thing I can think to do is to send Lawrence up there." Martinoni jumped at that and said, "Send him up."

In surveying the site, I realized that I would have to dive on the tide because the current was so strong that I wouldn't be able to stay on the side of the ship. I didn't have my own equipment but would be using equipment from Walter McCray, of Seattle. I walked out to the site at about ten o'clock at night, which was during slack water, to check out the project. I asked Walter McCray, "What's the story here?" McCray walked me toward the ladder, pointed to the equipment and said, "There's the gear. There's the ship. Now, go to work." I went straight to Martinoni and told him that I would not work under those conditions and with those attitudes. Martinoni said, "Listen. During the past three weeks, the divers have cut a hole of about a fifteen square foot area in the number four hold. I want you to burn back from that hole toward the stem." Those were my orders. I went down and burned fifteen feet toward the stem, which was more than the other divers had done in weeks. As I was burning, I realized that I was burning into the engine room because lube oil was leaking from the cut. I told my tender to let Martinoni know that I had reached the engine room. Martinoni didn't believe that I had gone that far and questioned the location of several different fittings. He then realized that I was at the engine room and directed me to burn across to the other side. I burned about nine feet across and fifteen feet up and opened the plate to expose the cargo. This was my first on the ship dive and I had accomplished more than the other diver had in three weeks.

Martinoni was thrilled! He said, "Do you have any more divers that can burn like you can?" I replied that I had one other diver who was a good burner. He said, "Get him up here. This job is yours. The heck with this." The union divers raised cane and tried to kick me off the job. Martinoni responded, "As long as you can't furnish better divers than those you have furnished, you can go fly a kite. Don't worry about Lawrence. He's going to be here until the job is over!" From then on, I took over the burning, but the original divers were kept on to break up the pasteboard boxes and feed the siphon with the cans of salmon. The number four hold had two decks, one at the top level, one at the bottom level and a one deck in between. I burned forty feet on the number four hold and thirty feet on the number three hold. Then, I burned about thirty feet up to the number one hold. I lifted all those plates out, exposing the whole side of the ship. That allowed easy access to the cases of salmon. I was on the job for five weeks. Old Martinoni was so pleased with the job that he sent me a case of Blue Springs scotch and a \$500 bill as a bonus. In those days, that was a lot of money.

### **The Missouri River's Hell's Canyon Dam, Helena, Montana**

When the Hell's Canyon Dam was built, there were only two penstocks, which is through what the dam's water goes through in the generators. A topside gate slides down to plug the hole

where the water comes through the generator. One of the holes had something blocking the gate from sliding all the way down, thus not allowing the complete cutoff of water flow. After reviewing the blueprints, I had the grate (the screen that keeps the logs and debris from passing through) lifted. I dove down 130 feet to check out the penstock. The structure was a nice square, smooth concrete form. Since I couldn't see anything, I felt around with my hands until I found a sloping wall. There, I discovered a large glob of concrete that had been dropped into the hole after the penstock was built. It was raw concrete that had dropped into the hole and it was blocking the gate. I secured a jackhammer and spade from topside and went back down. I popped a yard of concrete out and had it hauled up to the surface. I was called upon to do quite a few such small jobs.

### **Aircraft Carriers - Armor Plate Removal**

The shipyard had the job of modernizing three carriers, the USS *Roosevelt*, the USS *Coral Sea* and the USS *Midway*. The carriers had armor, seven and half inches thick, built into their sides in large, twenty by twenty-foot sections. Each section was bolted onto the side of the ship and the bottom edge was welded. The job was to remove those plates and replace them with torpedo bulkheads. Each of the sections weighed about thirty-seven tons. To put these carriers in dry dock and lift these heavy plates by crane would have been extremely difficult. It was decided that the plates would be removed while the carriers were in the water. A barge with railroad tracks on it and a railroad car, loaded with sixty tons of weight, was brought up alongside the carriers. This barge had lift pads welded onto it that were to match up with the lift pads on the armor plate. The procedure required the divers to go down and bum off the bottom edge on one of the armor plates. The weighted rail car was to be slowly run to the edge of the barge so that it would tip down into the water until it matched up with the pads on the armor plate. The pads were to then be shackled together. Then, the weighed rail car was to be slowly run in the opposite direction from the ship so that the armor plates would be lifted away far enough for a crane to pick them up and place them on a nearby pier. It was reported that the shipyard saved \$100,000 on each ship by removing the armor in this way. A report was sent to Congress and the shipyard received much recognition for the way that the project was handled.

### **A New Tugboat for the Diving Crew**

Our diving boat was a nice, wooden, fifty-foot long boat and had no equipment on it due to its size and capacity. When the Navy started to decommission tugboats and ships, I saw a 65-foot tugboat that had been decommissioned in Seattle. I convinced my boss, Walter Bruns, that we needed a bigger and better diving boat. He put in for it and we got a decommissioned tug. The tug was converted to a diving boat once it arrived in the shipyard. We secured the welding machines and air compressors behind the deckhouse and built quarters for the divers to change

into their gear. We made a big deck on the backend of the boat, which we used as a platform from which to dive. It was the best diving platform in the shipyard.

### **Johnson Island, Barrier Reef Blasting**

My experience and reputation as a diver was well known by several contractors in Seattle. When there was a job for which they needed a diver, they would call me. If I could get leave from the shipyard, I did those jobs on the side. They called it 'moonlighting.'

One such contractor, Phil Stewart, bid on a job on Johnson Island, which is 750 miles southwest of Honolulu. It is a little island that, from a distance, looks like an aircraft carrier sitting out in the middle of the ocean. In fact, it is used as an emergency landing field. It is home to over two hundred Air Force personnel who take care of any planes and crews that have to land on the island under emergencies situations. The job was to dredge the harbor to create a larger turning basin. A channel went through the barrier reef and into the turning basin. It had a pier for ships to dock. There wasn't enough room for the ships to turn around and get to the pier. The Navy surveyed the harbor and determined that there were eighty-seven coral heads ranging from five to fifty feet in diameter in the turning basin. They wanted the coral heads blasted out to a depth a twenty-nine feet and six inches at mean low water. The contractor indicated the job would take three months. I said, "I'll see if I can get a month's leave. I can blast those things out of there in no time!" The contractor responded, "You get the job running during your month of leave and I'll get a crew out of Honolulu to finish it off." I got the month off and headed to the job with five sets of SCUBA gear and an air compressor. I had picked up a book on underwater blasting from Dupont, but it didn't help me at all. By trial and error, I quickly learned the size of the charge needed to blast the top off of the coral. If you used a big enough charge, you ended up with a huge hole in the bottom of the harbor, which wasn't our goal.

We rigged up a 12-inch by 100-foot long H-beam and filled the grooves with concrete so that it would weigh 110 pounds per foot. This H-beam was rigged to hang under a landing craft at exactly twenty-nine feet and six inches. The craft would cruise along and when the beam hit a coral reef, I would go into action and blast it out. I found that I could move more quickly by skin diving than by using the SCUBA gear. My legs were very strong and my ability to hold my breath allowed me to zoom down to set the explosives and zoom back up. I became so efficient with this system of blasting, using just the snorkel and fins, that I was able to go like a house-a-fire! I was able to finish the job in three weeks!

I had an extra week of leave, so I trained some of the Air Force guys in SCUBA diving and wound up selling all my SCUBA gear to them for their recreation department. I worked extremely hard on that job, but it was a great experience and I had a terrific time. I was able to

take a few days to enjoy Honolulu with my wife, Maxine. We were given the keys to a red and white Ford convertible and had a wonderful time on the island!

### **Listening Devices Installation in St. Croix, the Virgin Islands**

My next job was in St. Croix, the Virgin Islands. A contractor from Seattle bid on a job to install listening devices at a depth of 3,000 feet on a firing range near St. Croix. Once the equipment was installed, submarines from the east coast could go to the range to fire torpedoes. The instruments were to test the speed of the torpedoes, a practice similar to the testing performed at the Keyport Torpedo Range. I worked on the equipment with the contractor in Lake Washington, in Eastern Washington, before the job started in St. Croix. When the equipment was shipped down to the Virgin Islands, I took leave from the shipyard and Maxine and I flew down. My job was to transfer the equipment from one ship and rig it to another ship, which was to lower the equipment into the depths. Most of the time, I was working in fifty feet of water in an area infested with sharks. They would swim around on the surface in the area where I had to dive. While I was underwater working on the devices, I could look out and see eight to ten sharks at any time. From a distance, one of the sharks started slowly swimming toward me, watching me the entire time, slowly passing by and then joining the group of sharks again. I was able to study the sharks during the job. I learned the sharks' patterns in their hunt for food. Like a seagull that located a fish, the sharks dove down and grabbed their prey.

I also came to realize that those who have been attacked by sharks, particularly in the surf, don't know that a shark is nearby. They attract the shark by slapping their feet while swimming, and it attacks. National Geographic did a story on sharks off the coast of Florida and Mexico and showed that divers can swim right up to them without being attacked. If the shark is not hunting for food and remains unprovoked, it will not attack.

In speaking to the photographer who filmed the movie *Jaws*, I learned that in order to get the shark to attack him in the underwater cage shown in the movie, they took ground liver, placed it in a porous sack alongside the boat and dragged it in the water. Once the scent of liver had its attention, they lowered the cage, which had a hindquarter of beef in it, and the shark attacked it violently. People believe that all white sharks will attack in this manner. They do not. The shark in the movie was provoked into a feeding frenzy. Unfortunately, the public is frightened by that representation and believes it as real.

### **Diving School in Key West, Florida, 1956**

In 1956, the shipyard gave me special permission to attend the Underwater Swimmers School in Key West, Florida. There were forty-nine people in my class. I was the oldest, at age forty. Every morning, we would run four miles before breakfast. Then, we would get our diving gear and

board a landing craft, which took us out a mile into the ocean. We'd have to swim back to shore. Each night and every morning, I would strengthen my legs and abdominals by doing five hundred flutter kicks off the foot of my bed. I was in much better shape than the others in the class. I knew how to swim and had the strength and endurance to do it.

Teams were set up for a navigating exercise and I was partnered with an eighteen-year old named Brad. Our mission was to swim underwater at a distance of a mile out from shore. Using a compass, we were to find our way to three contact points that were anchored on the bottom with a buoy marking them topside. Halfway up the buoyed line was a sign-in board, which we were to sign with our team number. Our number was nineteen. The teams had to swim underwater to each station, sign in and move on to the next.

I told Brad, "We are going to be the first guys to those stations because if all of the teams get there at the same time, it's going to be a crazy mess!" I told him to stay right on my back. "I'll navigate and get you there, but you need to follow me because I'm not looking back for you," I said. He stayed right with me. The little devil did a really good job! Of course, since we were always the first to shore, we were the last team off the boat for the exercise. I took off quickly to the bottom while most of the guys descended gradually. We made it to all the stations and to shore, beating the rest of the teams. The skipper in charge of the school had built a fifteen-foot tower on the beach so that he could watch swimmers who might be in trouble or might try to cheat by coming up to the top. During the navigating exercise, a group of Germans was visiting the facility. Later, one of the Germans told me that the skipper said, "Watch, the old man is going to be the first guy in on the beach," and I was!

After I completed the school, the skipper of the Underwater Swimmers School wrote a letter to the Admiral of the Shipyard, telling him of my performance and how well I had done at the school. Soon after, our hometown newspaper wrote a story about my accomplishments. The fact that I had done so well, at age forty, was featured in the article.

### **YMCA SUBA Classes and Rescue Squad**

Shortly after the Underwater Swimmers School, I started to teach SCUBA lessons at the Bremerton YMCA. SCUBA diving was new and a lot of people were interested in learning the sport. I also taught students from Olympic College for credit, as part of its physical education program.

I also trained a rescue team of divers that went all over the State of Washington to recover bodies from lakes and rivers. We were called at all hours to assist in finding drowning victims. We would then turn the body over to the proper authorities. Over an eight-year period, I volunteered my time and equipment for such searches.

Once, two or three planes went down off Whidbey Island in deep water. They were never able to recover them and determine the cause of the crashes. When a fourth plane went down near Lopez Island in about 150 feet of water, they wanted to recover the engines, for study, and the bodies, of course. The Keyport Navy divers went up to work on the search but came up with nothing. The shipyard sent us there with our sixty-foot diving boat, which could endure the bad weather we were having. With a combination of SCUBA and hard-hat diving gear, I was able to tie onto the engines and pull them up. We also recovered the bodies. With the engines recovered, they could do the testing that would help them discover why planes were going down.

### **Transfer to Superintendent of Salvage Office as Ocean Engineering Specialist, 1966**

In January 1966, I was transferred from the Bremerton Shipyard to the Supervisor of Salvage Office in Washington, D.C. as an ocean engineering specialist. When I first arrived, I was on the crew that inspected our Navy yards. I discovered that many of the shipyards were in poor condition. My specific area of inspection was the tugboats and barges. The first major job I was given was a submarine, the USS *Tarrow*, which sank at a pier at the Mare Island Shipyard. The sub sank on the swing shift and the Supervisor of Salvage Office called me in to take over the project. The conning tower was all that could be seen of the sub. We closed off the main deck hatches after the cable and electrical wires and hoses were taken out. My suggestion was to use the submersible pumps, which could be dropped through the hatch, and pump the submarine out. The submarine personnel wanted to blow it out, as you would do if the sub were in deep water. I was against that. You just never know what might happen if you blow like that. I tried to tell them that by pumping out the water, you could things and have control of the situation. We dropped the three-inch submersible pumps down into the sub through the conning tower and began pumping out the water. To assist in lifting it, we hooked a big wire onto the back of the sub and also attached a floating crane. We slowly pumped the crane with air as we pumped out the water from the sub. The submarine popped up to the surface with no problems. I went inside the boat and couldn't believe the sight. The muddy old Napa River water had settled all over the instruments in the control room and throughout the sub. It was a mess. Our job was to raise the sub and put it in dry dock. We had the sub in dry lock in three days. The project was a success and due to my work, I received a new title, the Senior Salvage Master for NAVSHIPS. I was really happy about that.

### **Saving the *Alvin*, Woods Hole, Massachusetts**

The *Alvin* was a small, two-man submarine that belonged to the Navy Research Lab operated by Woods Hole in New England. The researchers were putting the *Alvin* in the water 135 miles offshore, in deep ocean, off-the-shelf territory. The waters were very rough and a huge wave came up and hit the sub as it was being lowered. The two researchers got out in time, but the hatch was open when the sling broke. The sub sank in 5051 feet of water. The Navy tried, unsuccessfully, for ten months to salvage the sub and had given up. I talked to my boss about

letting me work up a plan of salvage and was given the approval. The first thing I did was have the surface ship, the *Mizar*, converted to handle the lifting of the *Alvin*. The work was done in the Boston Shipyard. My plan of salvage was to use another small submarine, which would drop a toggle down through the open hatch. My one concern was determining the size of line to use. I wanted to use the smallest line possible so that it was easier to maneuver, yet strong enough to handle the weight. A study group of engineers from NAVSHIPS and a civilian engineer from Ocean Systems worked on determining the issue of line size. I also enlisted the assistance of a young kid, who was a computer expert, from the Naval Research Lab. He was attending to the University of Michigan. In the conference room of my office, I gathered all the people working on the problem of line size. The engineers from NAVSHIPS and Ocean Systems all reported that they had not yet figured out what to recommend and needed more time. The young kid from Naval Research spoke up and basically laid out all the options of line size and how to determine the results of load on the line. I had never worked with computers prior to that but decided to go with his recommendation.

I then worked up a line and toggle that hooked onto the small, seven-man submarine, the *Aluminaut*. The *Aluminaut* spent thirteen hours on the bottom and accomplished nothing. It was a great disappointment. Then, bad weather delayed us for a week. While back at the base in Woods Hole, I discovered through conversation with some of the seven-man crew that utter chaos reigned among them during the thirteen hours underwater. The operator was totally confused as to what to do. There were continuous, contradictory commands from the sub crewmembers. Knowing what had occurred, I decided to work only with the submarine operator. I would control the topside operation and he would control the sub and operations below. It was agreed that he would take commands only from me. We went back out after the weather cleared. The *Aluminaut* went down and dropped the toggle bar down the hatch. We picked up the *Alvin* and brought it within a hundred feet of the surface. Because the sub weighed so much, we needed to get a hard wire on it before the toggle nylon wire stretched. At that point, I dove down, secured the hard wire and attached it to the *Mizar*. We then brought the *Alvin* closer to the bottom of the *Mizar* and hooked big rubber pontoons to hold up the sub. Each pontoon had to carry 8.4 tons of weight. One was secured to the sub and another at a lower depth, below it. If a pontoon blew, the next would catch and hold the boat. The system worked well and we started towing the sub to shore at about two knots. We had 135 miles to travel to the harbor area. Every morning and night, I dove down to inspect the pontoons and lines. We brought the sub into the harbor and had a floating crane pick it up and place it on a barge that would take it into Woods Hole. As a result of our success on the project, I was given an award.

## **The Azores Project**

Seven countries were involved in a United Nations project near the Strait of Gibraltar. They were Canada, Britain, Germany, France, Spain, Portugal and the United States, which furnished most of the finances. My part was to fix the mess that was left after attempts were made to place

instruments across the Strait to monitor submarines going in and out of the Mediterranean Sea. The piece of equipment weighed 74 tons dry. It was composed of a huge radar transfer chamber, such as you might see on top of a mountain, a 24-inch diameter screen, two 12-inch diameter screens and a cable that reached fifty miles to shore. The device was set on the bottom of the sea in 3,000 feet of water. It projected 125 feet up and rotated around, monitoring sounds. The instrument was originally placed on the bottom and the cable was hooked up. The contractor piled the leftover equipment on the pier and called it quits.

The problem was that the equipment never worked. Six months later, Admiral Zumwalt announced that the Navy would do whatever possible to put the device into operation. The admiral commanded that the salvage master be sent over, so I went to Paris for a conference on the project. I sat there listening to all the problems they had and what they thought they could do. One of the representatives asked who might be able to do the job. I said, "I'll do it!" The guy went crazy with excitement, jumping up and down! The job was mine.

On the way back from to Washington on the plane, I lay half-asleep and dreamed of all the things I had to do to get the job done. I decided to use the little cable-controlled Navy vehicle from San Diego. It was called the CURV III and had been built to pick up torpedoes that had gone down off the the San Diego area firing range. I asked the original builders of the CURV III to convert the vehicle to handle more detailed actions and to put a manipulator and long-range sonar on it. Then, I had it shipped to the Azores. My intent was to use the vehicle to retrieve the sonar instrument from the bottom. I designed a shackle that was hooked to the top of the device pad. I welded a piece of pipe over the shackle head and stuck a pin inside. Behind that, I placed an explosive charge. I pushed a button from the surface that fired the pin through and locked it into place. I was very pleased with that accomplishment, as we were then able to pull the instrument from the bottom of the ocean and next to the surface ship, the USS *Array*. We used pontoons to float it back fifty miles into shore. Once back at shore, the device was set on the pier and the electronics personnel refurbished it and made it operational. The fifty miles of new cable arrived at the dock. It was a two and a half-inch double-armored cable, piled on the pier. I had to coil it into the cable tank of the *Naubuc*. Twenty Portuguese men and one engineer worked on coiling the cable, as it would not lay down in a coil pattern. It would coil for a while, then kink up and become crooked. I ended up taking a large turn up the cable tank wall, tying the cable up with straps and changing the direction of the coiling. I changed its direction 26 times with the coils tied up on the wall each time. The British, who had built the cable, were on the pier. When they saw the cable tank coiling system, they said, "Man, you've got a bloody mess down there. You'll never get that cable out of there!" We headed out to sea and put that instrument on the bottom. Then, we started back to shore at a steady two knots, the cable peeling out of the tank as if it were coming off a reel. It was slick! The British couldn't believe their eyes.

I received a lot of credit from the Navy Department for the work I did in the Azores. About three months after the project was completed, I was asked to attend a conference at the Pentagon to explain how I accomplished the work. There were four people presenting on the project. I was the third presenter. I knew the job so well that I detailed every point and explained how each step was accomplished. When I finished, one of the 150 people attending the conference stood up and asked me where I had learned the trade. I replied, "Heck, I learned it on a farm in Missouri!" Well, that was kind of half the truth, but I did learn that when you go out to accomplish something, you stay with it and use common sense.

### **NASA Rocket Recovery**

The National Aeronautics and Space Administration, or NASA, built a rocket package to carry camera and electronic equipment, which was worth one and a half million dollars at the time, to take pictures of an eclipse of the sun. In March of 1972, they fired the rocket package. It was rigged to shoot off an internal rocket to blow off the engine and the nose cone and leave the rest of the package to float down by parachute to the ocean, where a ship would pick it up. The internal rocket did not fire and the whole package dropped into the ocean about eighty miles off Wallops Island, Virginia, in 6,000 feet of water.

NASA called the Supervisor of Salvage Office. I happened to answer the phone. The NASA official told me what had happened and asked if there was any chance that the package could be recovered. I said, "It can be recovered if you have the funds to do it." He said, "I'll be right over." Naturally, the project had to be discussed with my boss, Captain Mitchell, who told the NASA official that we had a little submarine with search and rescue capabilities. Mitchell, however, would not commit to the project, as he didn't want to take on the responsibility. The official left our office and immediately called me and said, "You seem to be awfully confident that you could go out there and recover this rocket with the little cable-controlled vehicle." I said, "If you can give us a good location as to where this rocket is, I can assure you that we can go out and find it."

I put together a recovery plan and headed to Norfolk, Virginia, where all the NASA officials were establishing what had happened to the rocket. Taking into account the speed of entry, the depth of the water, and the current, which they said was four knots from south to north. After determining how long it would take the rocket to get to the bottom, the NASA Officials marked a place on the chart.

### **The Rescue of the *Pisces III*, a Little British Submarine**

### **An Underwater Beacon off the Bermuda Diving Habitat**

**At Mare Island: A Decommissioned Submarine Moved through the Bridge to Fleet Reserves**

**The Salvage of a 512-foot Ship to Save Channel Shipping on the St. Claire River**

**Saving the USS *Tecumseh* from the Battle of Mobile, Alabama**

**Consultant for Crawley Maritime**

**Salvaging the *Patrick L*, a Ninety-foot Fishing Boat**

## **Conclusion**

To sum up, I did a lot of salvage jobs. I completed every salvage job that I started. I did not have one failure, which is unreal in this world. When you look at history, you see how many salvage failures have occurred. No one stayed in the salvage world like I did. I learned different jobs by using common sense and was able to accomplish every one that I set out to do. I have a great plan to salvage the *Tecumseh*, but because of politics and the lack of financial support, the ship will not be salvaged. I know that ship very well and that I could salvage it.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF EDWARD AUSTIN KOTH

Kensington, Maryland

Thursday, September 4, 2003

## PROCEEDINGS

INTERVIEWER: I'm at Navy Special Clearance (NSC) Team One with EM3 Edward Koth, a SCUBA diver with the Mark 8 Marine Mammal System. How long have you been in the Navy?

EM3 KOTH: I've been in the Navy four years.

INTERVIEWER: This is your first command?

EM3 KOTH: Yes.

INTERVIEWER: You said you were a SCUBA diver, right?

EM3 KOTH: That's correct. I came here as repair, just turning wrenches. Then, I went to dive school and transferred to mammal.

INTERVIEWER: Where did you go to dive school?

EM3 KOTH: They came out here. The people from Hawaii brought some instructors out here and they taught a class of us. There was about seven of us from this command who went.

INTERVIEWER: That's great. Did you go through any additional training to work with the mammals?

EM3 KOTH: No.

INTERVIEWER: What system were you assigned to?

EM3 KOTH: I'm not assigned to a certain system. At the time, we had a dive crew. We were called 'whiskey divers.' When an animal takes a mark away, it has to put it a certain distance away from the mine. Then, as a dive crew, we dive down and come back up and tell the handler who has the primary handle on the system and how far away the animal was from the mark.

INTERVIEWER: Explain how that works. How does the animal mark the mine or the mine shape?

EM3 KOTH: We get what's called a 'pinger.' When you are going through the minefields and the animal sees what it thinks is a mine or an obstacle underwater, it will pop up and the handler will know, through certain communications with the animal. It will give what we call a pinger or a marker. It sends off a signal. Our dive platoon can pick it up on some of their instruments. He will have the bite plate on it and the animal will bite it, take it down and place it next to what it

thinks is a mine or a shape that we deem as dangerous. Then, it will come back to the boat and you continue on to the minefield.

INTERVIEWER: How soon after the animal marks the mine do you go down and check?

EM3 KOTH: It's almost instantly. Right when the animal takes the mark to the mine, a buoy will pop up that's attached to the pinger itself. I would say that within a couple of minutes after the dolphin marks it, we check. Once the dolphin starts coming back from dropping the mark, we go down on the mark.

INTERVIEWER: You don't wait for him to mark every mine. For each mine you go down and verify?

EM3 KOTH: Yes. This is all for training purposes. If we were to do this in a real time scenario, we wouldn't be there because they would be going tactically into a minefield. So, obviously, we wouldn't be there. For training, we shadow the work boat that has the animal and every time they drop a mark, we come back up and tell the handler the distance and stuff like that.

INTERVIEWER: You tell them so that they know the animal has done it correctly?

EM3 KOTH: That's right, and they can give him the reward that is necessary.

INTERVIEWER: The animals wait for that reward?

EM3 KOTH: That's exactly right. The faster you are, the better it is, because as smart as dolphins are, they are still animals and they will forget why they are waiting there. They are trained to wait next to the boat, but they'll get bored or preoccupied and want to take off and they'll forget why.

My job has a lot of bounce diving. It's a lot of up and down. Some days, we can do 25 to 30 dives. We work all four animals, and each animal will take eight or ten marks, which isn't unlikely in a minefield. We try to train them every day. There is a lot of up and down. We don't really go that deep. It's very shallow water. We rarely go down to the depths of forty feet in shallow water.

INTERVIEWER: It's tough on your ears, though.

EM3 KOTH: Yes, there are a lot of ear problems. But luckily enough, we have enough guys who dive, so we can split it up.

INTERVIEWER: How long have you been doing that?

EM3 KOTH: I have been in Mark 8 mammals for about a year and a half now. It's been roughly a year and four months.

INTERVIEWER: Since you don't do that reinforcement in a real operation, what kinds of things were you doing when you went over to Iraq for Operation Iraqi Freedom (OIF)?

EM3 KOTH: When I was over there, we were pretty much attached to the USS *Gunston Hall*. We would help out in well deck operations and also do watches and stuff to help the animals and anything else that the handlers and the rest of the team needed. You need guys to help. We would pull the animals for medical reasons, for sonograms, for instance, and make sure they are doing well, and take blood. You need someone to hold the animal down. We just helped with basic needs for our platoon.

INTERVIEWER: On the *Gunston Hall*, you had a well deck and the animals were in there in pools, right?

EM3 KOTH: That's correct.

INTERVIEWER: How do you get them out of the pools? Do you put them into a boat or do they go right into the ocean?

EM3 KOTH: They go into a boat. We have what is called a 'beaching cart' and it has a net on it that the animal beaches in and out of. I guess it's about 4 feet tall. It's on wheels, like a big cart. The animal will beach up onto that cart and we close the mat up, which is called a 'beaching mat.' We close the mat up and we roll the cart next to the boat that's on the well deck. Then, the animal will beach into the boat from the cart. The boat then gets marched off the well deck and it gets transported into the minefield.

INTERVIEWER: The process is reversed when they come back.

EM3 KOTH: That's exactly what happens for the first one to come back in.

INTERVIEWER: So, you didn't join the Navy to work with mammals?

EM3 KOTH: No. I didn't know that this billet actually existed until I came over here to the VSW. That's what it was called at the time, or NSC Team One. I had heard about it. I just wanted to dive, to tell you the truth. I heard something about whiskey diving and the mammals needing a crew for diving. They were short divers. I put in my package, or I put in a request chit to get transferred from repair, from first lieutenant over to the mammals and it got approved. I've been here ever since.

INTERVIEWER: Was that a good decision for you?

EM3 KOTH: Oh, it was an excellent decision, because it allowed me to get changed to an EOD detailer. My EM detailer dropped me and I was taken as a mammal handler by an EOD detailer. Since I'm getting ready to go to UE school, it made it a lot easier for the transfer. I didn't have to go to my EM detailer. I got to dive every day and I love to dive. It was great. On top of that, I got to see how these systems work, how these animals work and how the Navy uses them. In our minds, they're pretty much the best thing the military has right now.

INTERVIEWER: It's pretty impressive how quickly they can clear an area.

EM3 KOTH: Yes. I think that in the past, we have been about 95 percent effective, which is pretty good.

INTERVIEWER: Is there anything else about that OIF deployment, or about your time here working with whiskey diving, that I should have asked about that I didn't?

EM3 KOTH: No. In OIF, my deployment was split in two. I was on the *Gunston Hall* for about a month. Then, we went forward to Kuwait. The problem with being on a ship with those twenty-foot pools is that you can't keep an animal in there for too long because of its attitude. They start to get depressed and their attitudes start to go down and they start to slip. Medically, it starts to become a problem.

INTERVIEWER: How's that? Is it stress-related?

EM3 KOTH: Yes. Well, there are two dolphins in a twenty-foot pool. Since they have been moved halfway across the world, they are really tense. Some of them don't sleep very well in the pools. Since they are so confined, they hate going in and being in there. They're still trying to

figure out a way to make it positive for the animals. But right now it would be like putting you in a closet for a month and then letting you go out on the town but telling you that you have to come back, you know.

INTERVIEWER: That's exactly how BM1 Robinson described it.

EM3 KOTH: It's the same thing. That's how it is. We saw it when we were on the *Gunston Hall*. The animals' attitudes just started to slip away. They didn't want to work. They were really lackadaisical. They were really lazy. They didn't have the energy they would normally have. We moved them off of the ship and got them into Kuwait in Miller pens, which was a lot better because those pens are much bigger. It seemed to definitely help the animals a lot.

INTERVIEWER: A couple of the animals ran, right?

EM3 KOTH: Yes, we had two animals run. One of our animals ran and another one ran when they were in Umm Qasr. Now, it's just a perfect example of the animal not wanting to come back, you know. It stayed in the general area. It's not like it went anywhere far. It stayed within our box and every couple of days we'd see him. He'd come back to us and let us know he was around.

INTERVIEWER: He just didn't want to go back to the boat?

EM3 KOTH: He just didn't want to go back to the boat.

INTERVIEWER: He wouldn't be the first sailor.

EM3 KOTH: That's right, exactly. He wasn't the first one that went UA. But it was interesting to go into Kuwait. The only thing I would say is that right from the get-go, you've got to get these animals out of those pools and into somewhere, like Kuwait. That should have been done right away. They sat on a boat for over a month, some for like a month and a half, you know. It's just not healthy for the animals.

INTERVIEWER: It's hard to explain to the animals about operational necessity, huh?

EM3 KOTH: That's right, exactly. I didn't know what was going on. I was just there to do my job. But there are a lot of lessons learned. It also has to do with effectiveness, you know. The animals aren't going to be as effective if as they could be if they are cramped in the pools.

INTERVIEWER: Are you glad you went?

EM3 KOTH: Oh, yes. It was a really good experience, an incredible experience. I didn't make it up north. We stayed in Kuwait and didn't make it up north. But just seeing a different culture and a different people was pretty incredible. Just being part of the whole operation was great.

INTERVIEWER: Did you get many VIPs or distinguished visitors come in and see the mammals while you were in Kuwait?

EM3 KOTH: Yes. We had a lot of them. It seemed like every day we would have some Kuwaiti family, some ambassador or somebody come down and check them out. It's pretty cool to have civilians come down and actually see, first hand, what we do with the marine mammals. There are a lot of rumors out there about how we abuse them or something. These dolphins live a lot longer than dolphins in the wild because they are kept so well and stuff like that. It's good to see civilians come down and get rid of some of those myths. That was my experience of a month on the boat and a month in Kuwait.

INTERVIEWER: Is there anything else we ought to talk about?

EM3 KOTH: No.

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF DR. EDWARD THALMANN

## P R O C E E D I N G S

INTERVIEWER: Go ahead. Identify yourself for the record.

DR. THALMANN: It's Ed Thalmann being interviewed by Dick Vann on the 2nd of May, the deuce of May, 2003.

INTERVIEWER: What are the date and place of your birth?

DR. THALMANN: My date of birth is April 3rd, 1945; my place of birth is Jersey City, New Jersey. Well, we're going to start the interview, and as they said in Alice in Wonderland, we'll start at the beginning, and when we get to the end, we'll stop. My first shot at joining the Navy was actually as an undergraduate, and I was rejected summarily because of my heart murmur, which I've had since birth. It has provided no physiological limitation, but back then, nobody knew what to do with it, so they decided that I should become an invalid. Why I picked the Navy, I don't know. In grade school, I fantasized about the Air Force, but it very rapidly became obvious because of my heart murmur that was a non-starter. Growing up around the shore, I had a natural affection for ships, so that was probably why I picked the Navy. At any rate, that didn't work, so when I got to medical school, I heard about the senior medical program. The Vietnam draft was still on when I was in medical school, and when I graduated, the deal was if you had two arms and two legs, you were in no matter what. If you could walk and talk, you were good enough to be drafted.

INTERVIEWER: Give me some years.

DR. THALMANN: I graduated in 1970, so it was in 1968. I decided that it would be better to enlist than to get drafted. I applied for the Navy senior medical program,

which basically commissioned me as an active duty ensign for the last two years of medical school and paid me an ensign's active duty pay, allowed me one year off to do my internship, but then required that I come back for a minimum three-year tour after the internship.

As part of the program, which I think it was called the Ensign 1915 program, I got a dream sheet in the mail one day. It read, "Welcome to the Navy. We have many interesting things you can do," and it listed them. "Why don't you fill out this piece of paper and tell us what you'd like to do in order of priority?" At the time, being interested in ----, my number one priority was to join a forward, what you would call a casualty hospital, with the Marines. I listed that as number one, which was probably a suicide wish, and for number two, I listed undersea medicine.

As a high schooler, I did get interested in SCUBA and had a SCUBA tank. I had done zero dives, because in New Jersey, there are not a lot of places to dive and --- - Bay was kind of muddy. You'd go down there and couldn't see anything. But I was interested in diving, so I signed. I was interested in sea hunt, so I put that as my second [third] choice.

Little did I know that the Navy was more interested in getting submarine medical officers than sending guys over to Vietnam, because Vietnam was winding down, so they gave me my second choice and told me I was going to go to sub school, which sounded kind of interesting. After I completed my internship in Montreal, I found my way to Albany, where I filled out a whole bunch of paperwork and was formally inducted into the Navy and told to report to New London, Connecticut, no later than 30 June 1970, I think. I went to New London and went through the course.

As part of the courses, the first big decision was where you wanted to do your dive training, and you could either do it in New London or at the dive school in Washington. However, they did point out that there were certain billets that were only available to individuals who trained in Washington.

INTERVIEWER: Just double-check this.

DR. THALMANN: You're hindering my spontaneity.

INTERVIEWER: Sorry. You were on a roll. I'm sorry about that. Go ahead.

DR. THALMANN: The deal was if you went to D.C., you could get any billet. Having gone to medical school at Georgetown University, going to Washington didn't seem like a bad idea considering they were going to pay us a whole \$25 a day. Plus, we were going to drive down and get mileage. Off to dive school in Washington I went with a class of about ten other guys.

INTERVIEWER: Did you have the choice of New London or Washington?

DR. THALMANN: Yes. You had the choice of New London or dive school, and I decided I wanted to go to my dive training in Washington. Then, I would be eligible for any billet.

At that time, the experimental diving unit was right in back of the dive school, and there was one door between them, and it went through the sick bay. The only other way to get from one ---- was to go outside the building and actually walk around it. But if you went to the sick bay and opened a door, you could go through. There might have been another door down in the machinery room. I don't know. But as part of dive school, we made a tour of experimental diving unit, which at the time, was busy upgrading its chambers to 1,000 feet. I looked around, and it looked pretty interesting.

I got the number billet two choice because I had the second highest grade in the class, and your choices of billets went in order of where you were in the class, so the top guy got to pick first and the second guy got to pick second. At that time, we just got to pick our subs, so I initially picked one out of Holylock, Scotland, because I had a cousin who was living in Scotland. Then, one of the other DMOs there gave me a big sob story and song and dance. He plucked my heart strings and convinced me to swap with him, so he got the boat in Scotland, and I took one out of Spain. It turns out he spent his whole tour in the yard, which from what I heard was much more miserable than actually being on patrol.

I got assigned to the USS *Thomas Jefferson*, and I got pulled out of sub school in November, a month early, because the medical officer who was supposed to make that patrol had an injury or was not physically qualified, so I missed the last month of sub school. To this day, I'm not sure what I missed, but it must have been something.

I did my first patrol, which was semi-interesting. I learned to sleep 18 hours a day, which is what all good medical officers do on sub patrol. I eventually qualified as a diving officer, which was pretty interesting, having to learn all the ins and outs of how a nuclear submarine worked. It was fun to get to drive one for a little while and hit that horn and dive. I became totally bored with the whole thing and had a couple run-in's with the XO which evidently angered the commanding officer, a guy named Jack Garney to the point to which he eventually made admiral and I evidently got a couple of crappy fitness reports from him. Those came back to haunt me later on. But the ultimate was that this guy was in great shape, such great shape that he died of a heart attack while running around the base one day.

INTERVIEWER: That's the way to go.

DR. THALMANN: Between my first and second patrol, I was angling to decide what I was going to do after my second patrol, and my first choice was to work at the emergency room in New London. I was really interested in casualty emergency medicine at the time, but I found out all those billets were spoken for. I poked around some more and found out that the experimental diving unit billets weren't taken, and I looked at them again and decided they were of interest. I made a trip to Washington and talked to Bill Spaur, who was the senior medical officer at the time. I told him I was interested in coming there, and having had some pretty solid credentials from my undergraduate internship in science and engineering. My undergraduate education was at RPI, which is a science and engineering school, so even though I graduated with a degree in biology, I had a math, science and chemistry background. It was a basic science background, which appeared would be of use to medical officers.

It turned out that before I went on my second patrol, the word went out that there weren't enough medical officers to go around, so you might have to make a third patrol. Of course, that had everybody up in arms, but we were gently reminded that the deal for two patrols was only if the needs of the Navy could be met, and they managed to remind all medical officers what happened if they didn't follow written orders. I went out on my second patrol not knowing if I was going to make a third patrol. But halfway through my second patrol, I got the word that I was not going out again because they evidently made the decision that they were just not going to put medical officers on board boomers anymore. It really didn't do them that much good, and an independent duty corpsman would fit the bill. I kept reminding my detailee, who at the

time was Ben Hastings, and his able assistant, who was a dive school companion named Ken Bayway, that I wanted to go to NEDU, which was the way it worked. If you didn't do that, they kind of forgot and sent you wherever they wanted, but they did send me to NEDU.

INTERVIEWER: The length of your tour on the *Jefferson* was two years?

DR. THALMANN: No. It was two patrols.

INTERVIEWER: How long did that take?

DR. THALMANN: Well, the first patrol ended in February, and then we were new on it for three months. The second patrol was three months, and at the end of the second patrol, I got relieved. I was actually on board the submarine for nine months. Right after I finished my second patrol in September of 1971, I went off and got married in Newfoundland. I remember when I arrived at NEDU, they were busy putting arterial catheters in divers as part of these physiologically based measurements to determine adequacy of underwater breathing apparatus. What you really wanted to know was the arterial CO<sub>2</sub> partial pressure. They asked me if I knew how to put catheters in, and I said yeah. I spent three months in the cardiovascular service, so I had some experience in sliding arterial catheters in.

Shortly after my arrival, I found myself on the bottom of the ED web pot ----, where there was a big fiberglass water tank called 'the ark,' in which the diver sat on a bicycle, ascended his arms through the wall of the arc, with rubber sleeves so that his wrist was outside. The arterial catheter was placed before he got in the water, and once he fit his arm through, we hooked it up to a little sampling thingy.

INTERVIEWER: Who were the other medical officers there at the time?

DR. THALMANN: Well, Bill Spaur was the senior medical officer. There was a guy named Caruthers, John Caruthers, who made the 1600 foot dive, and Taylor [name?] a year and a half later, and a guy named Brandon Wright, who was a Lambertsen protégé who eventually, tragically, took his own life because of personal problems unrelated to the military. That was it. There were four of us, generally. Brandon Wright eventually left, and a guy named Bill Braithwaite came. I take it back. Braithwaite was there initially. It was John Caruthers who replaced him because Braithwaite was brought in so that NEDU could put in and get approval to get a computer. Back in that time, a computer was a big deal and required years to get approval. They were going to get a PDP-12, a deck PDP-12. Braithwaite was brought to ED specifically because he had a very heavy computer background. He eventually went off to the medical informatics department in Denver, at University of Colorado, I think.

INTERVIEWER: That was out of the Navy?

DR. THALMANN: That was out of the Navy. But in absolutely predictable Navy timing, the whole thing was arranged. As the computer was going in the door, he was going out at the end of his tour. But he was there long enough to help get the computer set up at least, and he taught me about computers. At the time, the only computer-literate guy there was Tom Berghage, who tapped into the National Institutes of Health computer and seemed to be totally uninterested in the deck machine. Well, the deck machine came with a bunch of training credits, and since I was the only one interested, I got to spend over the course of the next year, six weeks in Maynard, Massachusetts, learning everything there was to know about the PDP-12.

INTERVIEWER: That's what I use here.

DR. THALMANN: Right. Before I left for Maynard, I just went to the library and grabbed a bunch of self-teaching manuals for Fortran. While I was in Maynard learning assembly language and stuff, I taught myself Fortran.

INTERVIEWER: They taught you assembly language?

DR. THALMANN: Oh, yeah, it was assembly language. It turned out that when I got back, we eventually got a Fortran compiler site and used very little assembly language.

But I had learned enough Fortran to be dangerous. As a self-imposed project, I grabbed the report that Bill Braithwaite had written. I think it was "A Cookbook Method For Computing Dive Tables," which was basically based on the Workman 665 report. He just systematized it.

INTERVIEWER: That was the HEO-2 tables, was it not?

DR. THALMANN: No. It was air. It was the Workman M-Value report. But Bill just systematized it. He had never written a program to compute the tables, so I took it upon myself to program the computer to compute Navy tables. I got the pertinent ED reports out and programmed in the pertinent equations and computed the first of the dive tables, which didn't look much like what was in the dive manual. I read the reports more carefully and found that while the tables, indeed, had been computed by a computer, a Univac at the David Taylor Model Basin, there was a lot of hand diddling. To make a long story short, I eventually figured out most of what the diddling was and came up with a set of M values that I called M valve 0, which did a pretty good job of computing the Navy tables as they appeared in the manual at the time.

INTERVIEWER: The Navy tables were computed, but they were also tested?

DR. THALMANN: Yes.

INTERVIEWER: Now, when an individual table failed, or in other words, had too many bands and six trials, were the whole set of tables recomputed to a new standard to get around the particular hit that occurred, or was just that one particular schedule that got hit diddled?

DR. THALMANN: At the time, I wasn't paying attention to that. But eventually, I wrote a paper on the history of the Navy air tables, in which I went into that in some detail. It was not a hundred percent sure, but in the first go around they recomputed all the tables, and in the second go around they just computed the tables that gave them problems. They only tested tables that gave them problems, so I think they got it down to six schedules. They would dive these things with only three or four guys. But at the end, I think, and this is where it is unsure, they recomputed the whole thing again, and it was not sure. I have written this all down in a presentation I made at a Navy workshop on air tables.

INTERVIEWER: Was that ever published?

DR. THALMANN: Well, Mike Curley, who's retired, is busy writing it up. But it turned out that I was supposed to basically edit what I said, and rather than edit what I said, which is just ----, I turned around and smoothed it into an actual paper.

INTERVIEWER: Where is that now?

DR. THALMANN: Well, he says it will eventually be published an addendum. I need to turn around. I think I can get it published at UVR. In it, I detail as much as I can gather from the reports and exactly what happened with the air tables. The bottom line was that they could not all be computed exactly, even taking into account affairs from the M values.

INTERVIEWER: Was that because some of them were manually adjusted?

DR. THALMANN: I think so. I think some were just manually adjusted. They just went in and empirically added five minutes here and five minutes there, yeah. But the point is that it was a method by which I learned to use the computer to program Fortran, making up these dive tables. Eventually, I programmed so that I could either put in the depth and time and get a schedule, or I could have it print out a whole set of tables. And reasonably using the PDP-12, actually depth enough to be able to read the blueprints and do minor repairs.

The first project I was given had to do with a 1600-foot dive. Initially, Bill Spaur thought I should be a subject on the dive, but when the question of my heart murmur came up, we decided the best thing to do was to keep a low profile on that and not have me be a subject. To be a subject, they would have had to get a waiver. He might have been right on that. He probably was right. At any rate, the first project I was given had to do with the fact that divers got ear infections on dives, and he wanted me to go to the literature and figure out if there was anything out there that could be done to prevent this. He also pointed out that ONR had spent a lot of money on guinea pig models of these ear infections in an effort to come up with some kind of a cure.

To myself to the library, medical school ---- Georgetown, being an alumnus, I was familiar with it, and ---- intimidating in the National Institutes of Health library of medicine, and I could also get right into the stacks without a bunch of bologna. I researched it and found an article in some relatively obscure journal about a doctor at a YMCA camp who figured out that an acid alcohol seemed to work well, and he eliminated swimmer's ear from the YMCA camp, where it had been pretty rampant

before. I went back and presented this to Bill Spaur. I wrote it up as a report. He and Brandon Wright reviewed it and had me in their office to assure me that I didn't know what I was talking about and that, in fact, the Navy had spent millions of dollars on researching this. Why was there some obscure guy who had figured it out twenty years ago when all these great brains who were now doing guinea pig models couldn't figure it out? I guess I got somebody mad and said, "Look, you sent me to find the answer. You didn't tell me what answer to come back with, so I came back with the best one I could find. This is it." They assured me that there was part of the Y report that the individual discovered, if the kids didn't leave it in their ear for a full five minutes, it didn't work well. I was also assured that there was no way Navy divers were going to take five minutes off to put the stuff in their ears. Well, my incredulity seemed to be worth something, because in the next deep dive we did, we tried this prophylaxis. It was the first ear infection-free dive NEDU had in the previous four years, so they reckoned they might have been on to something, or at least this doctor at the YMCA might have been on to something.

He wrote it up using the deep dive, and the rest is history. It's now a formal part of the diving that is used by the Navy for ear infections. Normally, you would be treating three or four infected ears during any given dive. It is now a thing of memory, and when they do occur, it's generally because the ear canal gets plugged up. But ear infections are no longer a major problem in diving in the U.S. Navy. It turned out that in those instances in which commercial diving companies tried to use it and failed, it was always because they couldn't get the commercial divers to leave it in for five minutes.

INTERVIEWER: You've got nothing but time when you get in the chamber. I would think that would be fairly easy.

DR. THALMANN: I guess those guys are all ----.

INTERVIEWER: They are unlike Navy divers.

DR. THALMANN: You can be a primadona, but you've got to be a primadona to follow those orders. Be that as it may, it's my legacy that I wiped out a disease single-handedly. I eliminated otitis externa from U.S. Navy dives. I don't know if that's up there with AIDS and SARS, but it's all I got.

INTERVIEWER: It's pretty close.

DR. THALMANN: It's close. Well, the Navy at that time was pushing for deep diving, and as part of it, we did a couple 1,000 foot dives in the Navy yard facility, and then we packed all our instruments up on the truck, went to New Orleans, to Taylor Diving and Salvage for a 1600 foot dive, which was really a big deal at the time. We had guys who were kind of unknowns at the time. For example, John Hallenbeck came by to do EEGs on our divers. A guy named Larry Raymond was chosen to be one of the medical officers on the dive. The other guy on the dive was John Caruthers, who had come in to relieve Bill Braithwaite.

I was just the junior medical officer on the outside. Well, it took us about two weeks to get everything set up, get all the wiring in. The day the dive went down, I kind of eased out of the ceremonies and went to one of the on-call rooms and went to sleep.

INTERVIEWER: You went where and went to sleep?

DR. THALMANN: They had on-call rooms with beds in them. I just went to sleep.

They were out there and had the divers. They were doing pictures, and there were speeches and stuff that didn't involve or interest me. Well, at some point during my nap, somebody rushed in, woke me up and said there were problems, so I went out to the control console. The divers had locked into the chamber, but it was all full of something in the air that didn't smell right, so they immediately vacated.

INTERVIEWER: Now, this was post-dive?

DR. THALMANN: Well, I'll get into the details. The Taylor chamber was basically a vertical wet pot and a horizontal living chamber. What they had was an automatic depth control system. We wanted to put the vertical wet pot where all the instruments were, at depth, the night before and let it sit overnight so all the instruments would stabilize. And the next day, the divers were supposed to come into the living chamber and simply compress to the first depth, I think, which was 300 or 400 feet. I forget. It wasn't very deep. We were going to go down in stages. A problem arose.

Well, it turned out that for some reason, and it may have been miscommunication, a Taylor guy was taking the vertical wet pot and sent it down, so then we got the tape changed. At any rate, the vertical chamber had gotten deeper. When we came in, in the morning, it was deeper than it was supposed to be, so they brought it back up to where it was supposed to be, and then the divers locked down. When they went into it, there was this mist in the air. They looked inside the chamber and said it was all foggy and smelled funny. The word they used was 'funny.' We immediately went into the emergency mode and separated the chambers and got the divers back into the horizontal chamber, and they began an emergency decompression. They said they couldn't smell anything in the chamber, of course, but who knew?

While Spaur and Bill Braithwaite wrestled with the problem of how to get the divers back to the surface, I was dispatched to try to figure out what the contaminate was and if we could do anything about it.

Taylor had a mask gas there and an operator, who was pretty good, took a sample. Well, we surfaced the wet pot and went in and looked. There was a little squeeze bottle of Freon in there that the technicians used to clean the pipes, the oxygen piping, and one of the bottles had been left in the chamber. The dip tube was below the surface of the liquid, so as the chamber compressed, of course, air went into the dip tube and filled the bubble above the liquid. While they were at depth, it was fine, but when they brought the chamber back to a more shallow depth, the bubble inside the bottle expanded and forced the liquid out the dip tube in a very, very fine stream, which atomized and filled the chamber with a large amount of fog. Well, we took some samples and verified that the only contaminant that was in there was the freon. There was a bunch of phone calls to Dupont, who cited some literature that they had had, but they basically convinced us that the Freon in and of itself was not harmful, so we didn't have to worry about any harmful effects to the divers.

We then dispatched a crew inside the vertical chamber with buckets of soap and water, and they scrubbed it from top to bottom. We compressed it and decompressed it a couple of times, and pretty soon we had the Freon well below the dangerous range.

At that time, we had a big conference that included the divers. We decided it was safe to go forward with the dive. The divers had only decompressed a couple hundred feet or so, so they went back to depth and latched up with the vertical chamber, and we began the dive.

During the dive, we had a UBA called a GE Mark 10, which was a constant PO-2 rig, and we did experiments looking at each PNS and balance, and Tom Berghage had his diver performance monitor, Sinbad. Actually, my main experiment, I recall, was audiometry. I was looking to see if there were any changes that I could detect. It was a reasonable experience. The Navy was pushing to go deeper and deeper at that time and pushed its saturation capability as deep as it could.

After several weeks in New Orleans, which has a lot of other stories associated with it that we don't need to go into, we reckoned the dive was a big success. A lot of the stuff got written up, and that was where we observed the peculiar feeling that the divers got while exercising at great depth, and we just instituted a whole bunch of other studies investigating that feeling, to see what its cause was. There were like half a dozen papers that came out of that dive, I guess. Plus, we showed that the Navy saturation procedures work well at 1600 feet.

INTERVIEWER: That means compression and decompression?

DR. THALMANN: There was some, but it wasn't random; it seemed to work okay.

INTERVIEWER: Did you have any hits when you decompressed?

DR. THALMANN: I don't remember. If there were, they were probably only a knee pain here or there. I actually don't remember. I've got it written down someplace, but I don't have it here off the top of my head. We went back to Washington, and things were fuzzy, but there was a lot of discussion over what NEDU should do. The chambers at the NEDU facility were only good to 1,000 feet, and we had just done the 1600-foot dive. The intent was to go deeper.

While doing a dive, Taylor reckoned that it was something we could do as

standard procedure. I then heard rumors that they were considering moving NEDU to San Diego, where the sat school was. Somewhere in there, Panama City came to our attention.

INTERVIEWER: Now, was this before the OSF?

DR. THALMANN: No. This was after. The OSF had been under construction for some years, and I forget when it started, but it was instigated by George Bond, and from the Man in the Sea program, and it was ----.

INTERVIEWER: That was totally separate, then?

DR. THALMANN: That was totally separate from NEDU. The OSF was to have nothing to do with NEDU. It was to be a totally separate facility run by the guys in Panama City. Yeah. The Man in the Sea program, I wasn't an expert in it, but with Barry Cannon's death, there was a lot of political stuff, and George Bond got put in Panama City.

INTERVIEWER: He was put to pasture?

DR. THALMANN: I think it was kind of a purgatory to get him. He had been appointed to a lot of highfalutin communities, but they wanted to kind of get him away from Washington, so he had been dispatched to Panama City. The OSF was supposed to be some kind of a simulation facility in which aquanauts would train and eventually go out into the real ocean and do wonderful things.

INTERVIEWER: Was that a follow on to SeaLab III?

DR. THALMANN: I don't know. I absolutely don't know. You'd have to ask somebody involved with SeaLab. I don't know how it meshed with SeaLab. As we all know, after Berry Cannon died, the whole program folded.

INTERVIEWER: Do you have any insights into the relationship of Panama City and sea lab?

DR. THALMANN: No. I came in well after SeaLab was underway, and you'd have to talk to someone else. I know little or nothing about SeaLab except what was written down. I had no personal interaction. At any rate, somewhere along the line, I guess it was decided that they were going to dedicate the OSF in Panama City and then mothball it because they had to let the contract finish, but they didn't set aside any operating budget. NavSea told NEDU to go have a look at that and see if that facility would meet their needs. I guess Colin Jones was the commanding officer of NEDU at the time. Then, he dispatched a guy named Don Chandler to go down to Panama City and see if the facility was suitable.

INTERVIEWER: Now, Don Chandler was a diving officer at NEDU at the time?

DR. THALMANN: He was an MSC Lieutenant at the time, and he was sent down to see if the Panama City facility would suit our needs. I was not privy to all these conversations. All I knew was from what I could gather by being there and listening to different people talk. But the bottom line was, yes, the facility seemed to have many of the things NEDU wanted, but no, it wouldn't exactly suit their needs. NEDU was instructed to go down there and look at it and try to get it buffed up so they could use it.

INTERVIEWER: That was in, what, around 1972?

DR. THALMANN: That was in 1972, right after the 1600-foot dive. I made several trips to Panama City with Bill Spaur and Bill Braithwaite to look at the facility, and it was about that time that Ed Flynn came back from Buffalo and ended up at NEDU.

INTERVIEWER: He had done an anesthesia residence in Buffalo?

DR. THALMANN: No. He did a two-year physiology post-doc. Some years later, he did his anesthesia residency at Bethesda. There was a political issue that commenced because the lab in Panama City, at that time known as the Naval Coastal Systems Laboratory, envisioned that NEDU would come in and provide the people to operate the OSF, but they, in fact, would be in charge of it and direct NEDU as to what should be done with it. Of course, NEDU had different ideas. They said, "Oh, we're our own command. We will be in charge of it. We will be in charge of diving it, and we will be in charge of scheduling it, and we will be in charge of it, period." A lot of political fighting went on to decide who was going to be in charge of the OSF, and at the end of the day, it was decided NEDU was. The lab had to get all their people out of there, and that was the end of it, although NEDU was instructed to work closely with the lab because NCSL was in the business of developing certain kinds of diving gear.

INTERVIEWER: Was George Bond still around at the time?

DR. THALMANN: Yes. We'd go down to NEDU. He was there, I'm not sure, six months or a year, and then he retired and went back to Bat Cave, North Carolina. At that time, we had begun to do these things called 'saturation excursions,' in which we were trying to develop tables. If a diver was saturated at some depth, how shallow could he go without getting bent, or if he was saturated at some depth, how deep could he go for a given time and still return to his storage depth? We had done a bunch of dives at NEDU North for that, and the first dives in Panama City were a series of saturation dives to look at the saturation excursion dives. That was a project that was already in the mill and was suitable because it already had prescribed a bunch of dives at different

depths down to whatever. Bill Spaur had mapped out a plan at NEDU in which we would begin going deeper and deeper to the maximum pressure of the facility, which I think was 2,200 feet.

INTERVIEWER: Oh, so it was a plan to go down that deep?

DR. THALMANN: It was planned to go to that, yeah. They did a 1,000 footer, a 1200 footer, a 1400 footer, a 1500 footer and had culminated in the 1800 foot dive, which was the deepest set dive that they ever did in the OSF, because as we were pushing deeper and deeper, the politicians in Washington were fighting amongst themselves and eventually decided that the Navy's maximum depth capability only needed to be 1,000 feet, or something like that. I'm not sure what went on.

INTERVIEWER: What drove that decision? Do you have any idea?

DR. THALMANN: I have no idea. Nobody asked me. My first tour to Panama City was short, and the reason is that as NEDU was in the throws of deciding on Panama City, I had been accepted into a post-doc at Buffalo. The original plan was that I would finish up at NEDU in July of 1975, go to Buffalo for two years, and then come back to NEDU. Well, somewhere before 1975, and I'm guessing it was July of 1974, moving to Panama City became a fire drill, and all of a sudden it was very important to move down there at once.

INTERVIEWER: Now, this was Buffalo early then?

DR. THALMANN: No. This was before Buffalo. I had the program set up. I thought I was just going to mark my time in Washington until we go to Buffalo. But around July, Ed Flynn, Ken Miwah and I went to Panama City on a per diem, and after becoming somewhat suppressed at the housing prospect, stumbled onto Sugar Beach

Condominiums, which made our stay really great. At that time, Sugar Beach was one of the few condominiums on the beach. The beach was actually fairly vacant back then. Sears was downtown. There was one movie house that always seemed to be playing a Walt Disney flick. We began going through the throws of getting the medical department moved to NEDU. Miwah was due to get transferred.

INTERVIEWER: Spaur was still the SMO?

DR. THALMANN: Spaur was still the senior medical officer. Flynn had decided he didn't want to go to Panama City; he wanted to stay in Washington and made kind of a big fuss about it. In the end, he ended up going to the dive school.

INTERVIEWER: The dive school stayed in Washington?

DR. THALMANN: The dive school was in Washington. There were no plans at that time to move the dive school, as far as I know. When the smoke cleared in January of 1975, I guess I was the only guy from NEDU besides Spaur who was going to be there. Interestingly, just before NEDU decided to move, my wife and I had moved from an apartment in Arlington to a house in Burke owned by a co-worker of hers whose husband was going off for a year or two of post-graduate work with the Army Map Service. They had just bought this brand new house and were worried that there would be nobody there to look after warranty repairs. They initially got stars in their eyes when some realtor had told them how much money they were going to be able to rent this place for. When that didn't happen, the guy came to me and gave me the deal of a lifetime. Basically, it was cheaper than living in Arlington because he had to pay utilities and stuff. We had moved to Burke, and just after moving there I ended up going to Panama City. I left my wife up there by herself for six months. But I gave her

a puppy dog. That made all the difference, or so she says. I thought I was going to have to be in Panama City another six months, so I decided to bring her down. We packed all our belongings in a U-haul. We had no furniture of our own at that time. She spent six months in Panama City at Sugar Beach, which was very nice. We were finishing up the saturation excursion dive, and then I, in June or July of that year, left NEDU and went off to Buffalo.

Now, just before we had moved to Panama City, a couple of guys from the Naval Ocean System Center in Hawaii came by. I think one guy was Ron Siple and the other guy was Kirk Jennings. They had been doing a lot of work with these very small high position pressure.

INTERVIEWER: Ron Siple, was he an ex-fellow?

DR. THALMANN: I don't know. All I know is his name. At any rate, they had this idea of putting this device in a wristwatch and using it for a decompression computer, and they came by to see if they could sell it. We said, "Yeah, it looks great." As you recall, at that time, I had been learning to program the PDP-12 by trying to program the Navy dive tables. We were pretty much up on algorithms, or at least I was, that we could have used the Navy air decompression tables.

INTERVIEWER: What year was this now?

DR. THALMANN: This would have been 1974.

INTERVIEWER: That was the inception of the Navy dive computer?

DR. THALMANN: Yes. It was a long time coming. The bottom line was if you sent them off to NAVSEA and told them, "Look! Hardware!" and that NEDU could provide you with the software to actually compute the dive tables, they did that, and the

SpecWar community looked at it and bought off on it. At the same time, the Mark 15 was coming down the pike, which was closer to UVA, which really had no tables. I guess that originally, they were going to use equivalent air depths.

The details are fuzzy, but at the end of the day, NEDU was asked to develop a set of tables for the Mark 15 with the idea that this would provide the software for these guys to put into their decompression computer. But it was reckoned the tables would be useful in and of themselves, even if the decompression computer never came to be.

So I wrote a protocol to test the tables, knowing that I was going to be going off to Buffalo before testing actually started and that somebody else would have to actually do the testing. My job was to set up the software so they could compute tables wherever they wanted. The guy who ended up in charge of this was a Canadian exchange officer by the name of Buckingham, who managed to finagle a tour at NEDU because the Canadians were building the saturation chamber DCIEM in Toronto. He had saturation experience, so he told them that the way to do it was to send him to Panama City for two years to learn everything about sat diving. They also had a line officer down there, and the names come and go. I'm not sure who is the right guy, so I won't say. But they basically had an exchange line officer and an exchange medical officer. Besides that diving, Buckingham was given charge of the development of the Mark 15 tables. Initially, he recognized that these were tables that were going to be used to lock in the submarines. Having no experience, he wanted to lock out as deep as possible. Somewhere, 175 feet came up, and it was decided that this was a depth that would be used to lock in and lock out, and that the table should be tested to 175 feet.

Well, at that time, the only way to do it was to actually compute the tables, have the computer print them out and then give them to the operators and have the operators follow them as closely as possible. Of course, when there were delays during descent, that made for some messy compromises. But the other problem was that the divers were so narced at 175 feet, they didn't know which way was up, because they were diving at a .7 partial pressure and 175 feet is, what, six atmospheres, so they had six atmospheres of nitrogen on board. Nitrogen narcosis was pretty prevalent. Plus, they were having problems, as I mentioned, in compressing and accounting for delays and a whole bunch of other stuff. I made at least one visit from Buffalo to try to help out.

INTERVIEWER: You were at Buffalo by the time the dive series got underway?

DR. THALMANN: Right. I was only called when they absolutely needed help and there was nobody else to whom to turn. What became apparent to me was the problem in having the handwritten tables, because we were actually using computed tables at Buffalo. We were doing 190-foot dives to do physiology experiments, and some of these dives had the potential to go on for forty or fifty minutes. I think the schedules went from thirty minutes to an hour and then to an hour and a half. There were big jumps. I computed a whole bunch of intermediate tables using my HP 65 calculator. We had them in hot stand-by if we had to go over the thirty minutes allocated by the diving manual. It turned out that we only did that a couple times. We were using the calculation to some advantage to compute tables at Buffalo. It was obvious to me that one way to get around it would be to have the tables computed to real time. Therefore, besides doing the stuff I was up in Buffalo to do, on the side I was also figuring out

how to compute these tables in real time by using the PDP-12 computer. They had that and the Hewlett Packard computer down there. When I got back from Buffalo to NEDU, I got into the thick of things with these tables, the Mark 15 tables, which I had absolutely nothing to do with the research I did at Buffalo.

They basically moved my wife to Panama City in January of 1975, and we spent six months on Panama City Beach at Sugar Beach and continued with work at NEDU. That July, I went off to do a post-doc at Buffalo, leaving behind the decompression computer work, which was in the form of a bunch of software computer tables and printed tables and that was about it, with Eon Buckingham. He was working with some computer contracts at NCFC to not only run the program in the PDP-12, but in the control room they actually had an HP 1000, I think it was.

INTERVIEWER: Now, was that connected to the chamber?

DR. THALMANN: Yes. Well, it was originally connected to the chamber to monitor strain gauges for engineering purposes. At the time, I guess it could record depth, but it really wasn't used to do that. Once the requirement for the strain gauges went away, they pretty much relegated it, and it just became a stand-alone computer, which was kind of clumsy because it had a paper tape operating system.

I went to Buffalo, where we bought our first house, and actually had a good time. When I got there, Claes Lundgren was there, and as I understand it, he was on sabbatical from Sweden because Ed Lanphier had left, and they were looking for somebody to run the hyperbaric lab. But as I rolled in, he was scheduled to go back to Sweden and in negotiations with the university. He had a plan for doing some studies in the chamber involving looking at static loading and exercise, and there was a plan.

There was kind of an apparatus that was partially built, et cetera. When I got there, I was essentially put in charge of the whole hyperbaric lab, even though I was only a fellow. They had nobody else with any experience. The chamber eventually fell directly under Herman Rahn, so Dr. Rahn was kind of my boss, although he didn't mess around except for really big picture stuff, especially when he had to write a renewal grant.

INTERVIEWER: He was gone there for a good part of...

DR. THALMANN: He left within three weeks of my arrival. Then, he came back four or five weeks before I left. For that year and a half, he was negotiating with Buffalo. I don't think there was any doubt he was going to come back, it was just how much they were going to pay him and other things that I wasn't privy to. I found myself in charge of this lab, which had, I think, four full-time guys and a couple of part-time guys. Plus, there were peripheral investigators, like Mary Ann Rokitka, from the nursing school. She was our part-time chamber operator and log keeper. I'm not sure if we had one other person who wasn't in the lab full-time, but one who used to help out when we did chamber operations.

We set up the apparatus and booked a bicycle odometer box, the electric box, and we figured out how to get true entitle sampling at the great depth without mixing, and what precision we needed to analyze the gas mixes. It turned out that we needed to go out and buy volt meters with two more decimal places on them that came with the specification in order to get the precision we needed. All our gases were measured at one atmosphere, so we were at 190 feet, which is almost seven atmospheres.

The gas concentration was divided by seven, so we basically needed seven

times the precision in order to get oxygen consumption measurements at 190 feet, which would be in the same ballpark as what we were using at one atmosphere.

By and large, my time at Buffalo was taken up in building the apparatus and testing it and eventually gearing up to do the study, which consisted of a few subjects, one of which was myself. Another subject was a guy by the name of Ron Smith, who works over at the lab, and another was a graduate student named Dennis Sponholtz, who came into the hyperbaric lab when his interests changed. It turned out that the three subjects in the paper really all worked in the lab, so it worked out really well in terms of scheduling and other things. We didn't have to work around a lot of stuff.

Since I was a Navy undersea medical officer, I could also be medically responsible for the whole operation, which was convenient because other individuals at Buffalo would have to go out and beat the bushes at the VA hospital, which was across the street, or they would have to go to some other hospital to get a physician to be medically responsible for their studies. As I recall, while I was there, I also began to assume medical responsibility for just about any study that went on in the lab, because they reckoned having an in-house doctor was a boom, at least a licensed doctor, in New York. Al Zock, I think, was an MD, but I don't know whether he was actually licensed or ever actually treated patients. I didn't treat patients, but I was there for emergencies.

INTERVIEWER: Did you do treatment for decompression sickness at the time?

DR. THALMANN: We treated the odd case. There wasn't a lot of diving up in the Niagara fRahntier. But I recall we had one or two cases of decompression sickness that we treated. From our experimental dives, we only treated one, and that was in ----.

Hopefully, we'll get to that story, but he was the only guy to ever get bent in the profiles we did for the study.

I spent most of my time in a bathing suit in the water. They had this big, circular donut shaped pool. It was eight feet by eight feet by eight feet by, I guess, eight feet wide, but the diameter, the inside of the circle must have been 60 feet. It was a pretty good size. As I said, the chamber, at that time, was funded by ONR. In order to keep the ONR grant going and before Lundgren got there, they did this big study with putting mice in the chamber, doing behavioral studies at great depth and writing it up in some behavioral magazine.

When I got there, we were actually progressing to manned studies. The ONR grant came up for renewal, and I remember Herman Rahn called me into his office. We sat down and wrote some stuff. It's all kind of blurry. But the bottom line, since I was there and actually making progress, was that we got this apparatus built. We were almost ready to test subjects. ONR continued funding it. I was probably responsible for at least keeping that job slot open while Lundgren was negotiating, because if that grant hadn't gotten renewed, and the hyperbaric team had gotten broken up, which was composed of incredibly talented guys, I don't know if he would have had the same degree of expertise that he had when he got back.

At any rate, we started doing runs on a regular basis. We did esophageal balloons. From all my leadership training, I knew that if you were going to get the troops to do something, you had to do it first, so I turned my back, went into a corner, and vomited and made all kinds of unhealthy noises. I retched and convulsed, but in the end, I turned around, and there was an esophageal balloon catheter coming out of

my nose. I had kind of persuaded everybody else to at least give it a try. We commenced on our exercise runs. We did runs at the surface, which were really 15 feet, because we needed 15 feet of pressure just to get the samples out of the chamber. Anytime we did a wet or dry run, we did them at 15 feet. Our other depths were 60, 120 and 190 feet. During the run, we would drain the wet pot and put in a seating arrangement, so you could pedal a bicycle dry. The 190-foot runs were fun because everybody was narced out of their mind with Nitrogen Narcosis.

There was more than one time when the whole experiment just collapsed because somebody would not stop laughing, and once you started laughing at 190 feet, you couldn't stop it. The whole dive had to be aborted because everybody was so busy laughing and doing goofy things that there was no way that any useful work was going to get done.

I was in Buffalo for the great blizzard of 1977. That was interesting in and of itself. But during the whole great blizzard, I used to come into work every day and go swimming. It turned out that the pool at Buffalo was not heated by natural gas, which was in a shortage, but rather by a coal-fired steam plant on campus, and the coal-fired steam plant, by the fall, had all the coal it needed for the whole winter, so we plugged away.

Then, I ended up sharing an office with a guy named Hans Ornhagen, and I got to know him pretty well. I then got involved with Hugh Van Liew over the papers he wrote with Mike Costolla, trying to come up with predictions on bubble growth. I spent a lot of time delving into his equations and also audited the pertinent courses, cellular physiology and cardiovascular physiology.

I actually wasn't allowed to take courses for credit. That was part of the agreement. I was a Navy post-doc who was just up there to learn, but not to get credit. Those courses were incredibly interesting, though. Buffalo, at that time, had probably the best-integrated physiology program in the country. Herman Rahn was professor, and he still did a lot of teaching.

INTERVIEWER: Boy, those are some good people.

DR. THALMANN: Yeah. Don Redding was there, and I'm trying to remember who else. He was the head of the department at the time, and I guess he ventured over to the medical school. I got really interested in what Van Liew was doing and got into the math and began to learn about solutions and numerical analysis and the stuff that was maybe one or two courses up from what I had had in undergraduate school. By the time I left Buffalo, I was dabbling in bubble models. We finished all of the exercise experiments in the prone position, which basically involved exercising divers on a bicycle in the prone position up to 150 watts in the water. We also did maximum oxygen consumptions at different mouth over under pressures to see what effect that would had. We did find that if the static load was too positive, the divers got terribly short of breath, uncontrollably short of breath at the end of a heavy exercise.

INTERVIEWER: Now, Lundgren was still away at this time?

DR. THALMANN: He was away, yeah. He came back and visited once or twice, and then for the last month or so, he was there full-time because he had accepted the job and come back. I basically did these experiments on my own, but he would come back, and we'd sit down and go over the data and decide what the next move would be.

The plan was largely the one he had mapped out in the beginning. There

weren't a lot of questions as to what the big picture was, but there were a lot of little pictures that needed to be painted, sampling techniques, experimental techniques and what could we ask the subjects to do. We dabbled over whether to do arterial catheters and decided that was a no-go, because the last time they tried it, they made the doctor go over to the VA for six months to learn how to put in catheters.

INTERVIEWER: You had already been doing that, though?

DR. THALMANN: Yes. I had, but not officially. There was still a lot of credentialing, jumping through hoops.

INTERVIEWER: Sure.

DR. THALMANN: We did decide on esophageal balloons. In conjunction with Clouch, we got into how to make them, how to optimize them, and what kinds of errors, because they were too big or too small, et cetera, et cetera. Hugh Van Leu got interested in gas mixing, so we ginned up a couple of experiments for him with mixtures of gasses with different densities, up to and including an SS-6 mixture. Everybody called it the 'Van Liew strange gas,' because SS-6 is incredibly narcotic in breathing these very dense gas mixes.

INTERVIEWER: That was true even at one atmosphere?

DR. THALMANN: Well, we'd breathe them at 190 feet.

INTERVIEWER: Oh, 190 feet, oh my God.

DR. THALMANN: We had some interesting out-of-body experiences breathing some of that gas.

INTERVIEWER: No.

DR. THALMANN: It was a good time. We had a free hand and could just do things

that we dreamed up, and we could just try stuff. While we were following a plan in this big research study, on the side, we did a couple of studies for some commercial companies that had some unexplained deaths on their UBAs. The only problem was getting the guys to dive with a UBA who had held the head of a dead man.

We did some studies just to determine whether the UBA was at fault or not, and we never did find anything wrong with any of the UBAs. Like I said, we did some stuff for Van Liew. As an aside, a duck took up residence outside one of the lab window. That just fascinated Herman Rahn, who had the lab build a switch so that he could see whether the duck was on or off its egg, and when the duck was trying to get food. He had his graduates go out and either weigh the egg or do some other measurements on it. There was a little box in the lab called 'Dr. Rahn's duck-on duck-off switch.'

There was also a guy there named Bruce Larroway, who was an apprentice jeweler. His father was a jeweler, so he was a jeweler. He could do hand engraving and make jewelry, but he had taken courses in engineering and was a machinist, a draftsman, a very precise individual who could take a piece of machinery and make it do all kinds of things that it wasn't designed to do. He was one of the very, very talented guys who, given a free reign, could just solve about any problem you could think of. I was sorry to leave Buffalo. I really, really liked it.

When I got back to Panama City, I got up to my eyeballs in these Mark 15 dives. They had tried doing 175 footers, but it just didn't pan out because the divers were so narced. They got into a bunch of dives in which they just had a lot of bends, one right after the other, and had to stop, but they didn't know why. It was very frustrating because they were all trying to dive from tables.

INTERVIEWER: Which value were they diving at this point?

DR. THALMANN: Well, these were called 'M Values' at the time.

INTERVIEWER: Which M Value table was it?

DR. THALMANN: Well, there were three M values, M values 1, 2 and 3.

INTERVIEWER: M value 0 was a Navy ----.

DR. THALMANN: M value 0 was the one that computed the Navy tables.

INTERVIEWER: It did so as close as it could?

DR. THALMANN: M value 1 was a slight modification. When I plugged M value 0 into .7, in which you simply changed one line of Fortran, instead of computing the oxygen partial pressure by multiplying the F02 times the ambient, you just put in P02 equals 0.7 and that was it. You just changed that one line in the Fortran program, and whap, you went from air to 0.7. Lo and behold, it began predicting some strange things. For example, you could do repetitive air dives at much, much shorter decompression times than the manual called for. I began reading all the reports and how they computed through repetitive dive tables and figured out why that was. But it also turned out that getting bent on a repetitive dive was fairly rare. That was probably because the repetitive dives always assumed that the 120 minutes you should control, though which we almost never did for most air dives, introduced a pretty healthy shot of conservatism into that second dive.

I had three sets of M value 1 computed tables. The first dive was all based on 190 foot dive for 30 minutes with a one-hour surface interval, or maybe it was two hours. Anyway, let's say it was a one-hour surface interval followed by another 190 foot dive, and that was the basis of constructing M values 1, 2, and 3.

M value 1 was constructed such that the first 190 feet for 30 minutes was pretty close and actually slightly longer than what was in the dive manual. The second 190 for 30 was whatever the model predicted, which was pretty short. Instead of having a 30-minute residual nitrogen time, it was to only like having a five or 10-minute residual nitrogen time. M value 3 was constructed so that the M values were adjusted, so you did the first 190 for 30 and had a one-hour surface interval. The second 190 for 30 was the same schedule as the dive manual predicted. The M values were adjusted to make that long enough, and as such, the first dive got a lot longer.

INTERVIEWER: What did you do about controlling time on the surface?

DR. THALMANN: Well, it was the 120 minute interval.

INTERVIEWER: You just left it at 120 minute?

DR. THALMANN: Yes. I left it at 120. All I did was change the M value such that on the second dive, the decompression schedule was that of a 190 for 60, which was what the tables called for. They called for a 30-minute residual nitrogen time. Then, I let the model predict what the first schedule was going to be, which, as you might imagine, was longer than what was in the dive tables by quite a bit. That was M value 3, and M value 2 was halfway in between. I made the first and second dives each a little bit longer. Basically, the way it worked was in going for M values 1, 2 and 3, I began shifting decompression time toward the first dive and making the second decompression dive longer. I think at the end of the day, we ended up with M value 3.

INTERVIEWER: Now, was that before you got back down there?

DR. THALMANN: No. It was right after I got back down there. If you look at the first

report, you'll see that it is divided up into phase one and phase two, part A and part

B. Part A was the part that went on when I wasn't down there.

INTERVIEWER: That was the Buckingham section?

DR. THALMANN: That was Buckingham. When I got down there, I said, "Well, the way to do this is to get the dives in real time," so we spent a month or two getting the software to run in real time. Oddly, one of the problems we ran into was on the PDP-12. The digits were 24 bits long, whereas in the Hewlett Packard, they were only 16, which actually reared its ugly head in several different ways in the software. We did a lot of iterations in which we counted iterations, and I had assumed the digits were all going to always be 24 bites -- bits, and it wasn't. The bottom line was that I spent a lot of time at the computer jacks down there. We eventually ginned up a way to do the dives in real time, and we could actually have the computer monitoring depth. I'll go on record as saying I think those were the first digital decompression computed dives ever done. We actually had a digital depth gauge monitoring depth, a digital computer computing not the fluid mechanical stuff that had been going on up in Canada for some time, but actual digital real time, during which the schedules were computed as the dive was progressing. Once we did that, things went a lot more smoothly. But we did back off from 175 feet to 150. We decided going below 150 feet was a non-starter.

We finished up with the first phase, and lo and behold, we actually got a pretty decent set of tables down to 150 feet, but nowhere had we tested them, because we were told those weren't important.

INTERVIEWER: I remember that.

DR. THALMANN: I remember making a couple of computer runs and telling Bill

Spaur there was a bit of a problem. He asked, “What do you mean?” I answered, “Well, the 60 for 60 involves a 10 minute decompression stop at 10 feet.” In the end, we said, “Well, shoot, they got their decompressions, so having to stop 10 minutes at 10 feet is not a big deal. If they dive for only 40 minutes, then it's only a couple of minutes.” It turned out we were wrong. So what we did was fit the tables to 150 footers, 100 footers and 75 foot multiple repeat dives that we had done, and we adjusted the M values to fit those dives. Then we let the chips fall where they may based on the dives. Whatever the model computed was fine. Well, we sent those tables off, and there was this great howl and wailing and gnashing of teeth coming from downtown, because at the time, the Navy had decided you couldn't do decompression diving. Somehow, it was inherently dangerous, and the only way you could do decompression diving was if the country itself was under attack.

Then, two things happened at that time. Bill Spaur went on a campaign, saying, “Well, if you're going to do this Mark 15 decompression computer stuff, decompression dives will become a way of life, and we shouldn't be afraid of them.” We said, “Gee, guys, if you give us another half a million bucks, we'll be happy to do another set of dive trials and concentrate on the limits to get the limits buffed up.” Well, they acquiesced and gave us the money. When we did the phase two testing, which was a separate report, we basically concentrated very heavily on limits and doing multiple no-decompression repetitive dives. When we finished that up, that was the basis for the tables that are in the dive manual, those two dive series.

We eventually went on to do a third dive series, which I promoted and managed to convincingly call it the air algorithm series, saying, “Oh, we have this algorithm that

works on 0.7. Let's see if it works on air.” At the time, it gave predictions on air dives, which were much, much longer than those in the manual, and we were under the naive assumption that the schedules in the dive manual were all okay, which we know now not to be true. It was kind of around that time that Paul Weathersby had gotten together with Lou Homer up at NMRI and began looking at the probabilistic model.

INTERVIEWER: Now, as a part of the air algorithm, you went back and tested some standard air tables?

DR. THALMANN: Yeah. The purported reason was to test some schedules out of the dive manual. The real reason was that the computer software wasn't yet ready, and we had dive subjects coming in. We had a little per diem identified, and we didn't want to give it up because it might go away, so I suggested that we try some dives right out of the dive manual initially. We tried the infamous 60 for 180, and since the dive was cold, we came up on a 60 for 200 schedule. That was for three out of the first ten guys we tried. Very rapidly, we found out that the 60 for 180 out of the dive manual gave guys a lot of decompression sickness, which surprised the heck out of us.

By then, we had gotten the software out, so we moved on, but it turned out we increased the 60 for 180 decompression time from 75 minutes to 225 minutes before we finally got a schedule that we thought was reasonably safe. But the whole point of the air algorithm was to take the 0.7 algorithm and plug air back in to see if it would compute air dives. It was during phase two that we went from M values to V values. We went to V values because the decompression model was loosely based on a gas phase forming that kept the over pressure inside the gas phase constant, but since it was a gas phase, I decided the numbers more reflected a volume to volume.

Then, we made some other changes to the model in which we actually looked at AV oxygen differences rather than keeping the venous oxygen the same. We said that the extraction rate was constant. In using the hemoglobin association curve, we actually computed what the venous oxygen tension would be, given the arterial oxygen tension and tissue oxygen consumption. I think we ended up at V value 50-something.

INTERVIEWER: It was V value 50?

DR. THALMANN: Yeah, for the air algorithm. There were a lot of V values in between it. Every time I tried a new one, I just gave it a number. A lot of them never made it outside the computer lab. I tried them and discarded them. But then, the next time I made a new one, I just incremented the number by one. At the end of the series, we had come up with a pretty decent air algorithm, I thought. I guess under one scenario, I could have run off and gotten NAVSEA to use that as the basis for a whole new set of air tables. There were a couple reasons as to why I did not do that. We're moving forward in time, to when I was gearing up to going to England, and we had finished up the 0.7 table. We were happy with it. John Zumrick was coming on board, and I showed him how to use the software, but he seemed incredibly uninterested in it. When I went off to England, the whole thing stopped; nobody was interested in it, though NMRI was investigating probabilistic decompression.

INTERVIEWER: What year was that?

DR. THALMANN: That was in 1985. That was when I left NEDU to go over on exchange to England. All that testing stopped at NEDU. When I went to England, I tried to garner some interest in getting a joint program going with the British and the

Americans to come up with a single set of helium tables, but that didn't work out.

Before I left, we tested some helium oxygen tables for the Mark 16, which were all bounce dives, and we eventually went down to 300 feet for 30 minutes.

INTERVIEWER: So before you went to England, you did the Mark 16 dive?

DR. THALMANN: That's right.

INTERVIEWER: By that time, Frank Butler was there, or was he?

DR. THALMANN: No. He didn't get there until after I got back from England.

INTERVIEWER: Okay. So you did part of the ----?

DR. THALMANN: We had finished up the 0.7 PO<sub>2</sub> and those were published.

Then, EOD came. They wanted some dives. We did that. I finished the study, wrote the report, and those got published. Then it stopped because nobody else there was interested.

I guess it was Tom Hennesy who had ginned up a set of tables that gave them restricted bottom times. If they went outside of those bottom times, they went onto these rather emergency procedures, which didn't help them in their operation that much. What I did was fit the rhythm to the existing tables as best I could, with the idea to interpolate between the tables and give them tables in ten-minute increments, which helped them quite a bit operationally. They went out and tested the tables, and they worked fine.

INTERVIEWER: They tested them in the lab or out in the water?

DR. THALMANN: It was done in the water.

INTERVIEWER: They didn't do any lab testing?

DR. THALMANN: No. They didn't do any lab testing; they did it in the water. We

had a protocol that required them to have a medical officer on scene and a hyperbaric chamber available within thirty minutes. After they accumulated 300 dives, I think, the supervisor of diving would review the data and give either up a thumb's up or a thumb's down. They only had one bend in 300 dives, I think. It was a pretty low number, but they were happy with it.

INTERVIEWER: Now, was David Elliott there at that time?

DR. THALMANN: No. The first year I was there, a guy named Donald Makay was the senior medical officer at INM, and Ramsey Pearson was at the sub school. Then, Makay left, and Ramsey Pearson came to be the senior medical officer for the last year I was there, the second year.

INTERVIEWER: Did you cover all the important stuff there in England?

DR. THALMANN: I thought it was important.

INTERVIEWER: In other words, you just shifted immediately?

DR. THALMANN: No. When I immediately got there, I spent the first month spinning my head because I didn't know what to do. I did get plugged into one thing. They were coming up with the big diving ship they were building, and I can't remember what the heck the name of it was.

INTERVIEWER: *Clansman*?

DR. THALMANN: No. It wasn't the *Clansman*. That was their contract diving ship. This was the one they were building that was going to have the big diving bell in the middle, but they eventually scrapped it. But they had all kinds of computer software. They had written specifications for it and were testing it, so I got involved in that. I was uninterested because the software was all screwed up, as far as I was concerned,

but I was told I was absolutely not allowed to touch it. In England, it was forbidden for anybody but a certified, bona fide, stigmatized software guru to touch software.

All the medical officers had no business touching software, but eventually I got to the point at which I got involved in two projects. One was to extend the saturation upward excursion limits all the way to the surface. They had a ship called the *Clansman*. Though they went out and did 300 meter dives periodically, they spent most of their time at depths of 50 to 80 meters, salvaging airplanes around England, so every time they did a dive, they would come up on an experimental schedule and re-saturate for 48 hours, make an upward excursion, and come out. In doing that, I got enough data that we were able to extend the upward excursion almost all the way to the surface. When I left NEDU, the shallowest upward excursion you could do was from 225 feet to 150 feet. That was the shallowest that was ever tested at NEDU.

INTERVIEWER: Now, you had to sell that concept over there in order to make that project?

DR. THALMANN: Yes. They were very easy going. In contrast to the U.S., the supervisor of diving actually owned all the divers, so he was able to get the divers to do what he wanted. Plus, he ran the *Clansman*. Once I had sold the supervisor of diving on it, we wrote the protocol, and the guy on the *Clansman* had to follow along, even though he was somewhat skeptical of the whole thing. Another big thing I got involved in there was coming up with some pretty major improvements, like the thermal protection garments for the Royal Marines.

INTERVIEWER: You had started out talking about the 75-meter stuff. Was that just a quick and dirty project?

DR. THALMANN: That was a quick and dirty project. They said, “Hey, we've got these tables, and if we go one minute over the table, we go from an hour of decompression to four hours of decompression. We don't want to do that. Can you help us?” I basically took the 75-meter tables and came up with a set of H valves to fit them according to the Mark 16 model. Then, I interpolated between the tables and came up with a set of tables in five and ten-minute increments, helping the operation quite a bit. The tables were used mainly for EOD purposes.

INTERVIEWER: Those were the ones that they tested out in the water?

DR. THALMANN: That's right. The deal was that they could test them in the water. The supervisor of diving did not want to do a big in-house production. I think we did two big dives while I was over there, and those were quite expensive. They were to test bailout systems for some of the deep saturation rigs that they were testing.

INTERVIEWER: Was that for commercial diving or for military?

DR. THALMANN: It was for the military. As I said, they were building this big diving ship, the name of which escapes me. I wish I could remember it. I know somebody will remember the name of it. It was a big, huge dive ship.

INTERVIEWER: Was it ever completed?

DR. THALMANN: Yes. It was completed, and it went out, but as far as I know, they had a whole lot of trouble with the dive platform. It eventually went from being a dive ship to going around, towing sonar. While I was over there, the Royal Navy formally got out of the saturation business. I actually was on board and was present for the last operational saturation dive ever done by the Royal Navy. Then the *Clansman* was put back into Falmouth. I think they went out one more time and did some training dives.

They then brought the ship to Portsmouth, and the diving system was unloaded, and the ship was returned. The *Clansman* was a commercial ship that was under contract to the Royal Navy, and the company crewed and ran the ship. They didn't have a captain; they had a craft master or something equivalent. But the Royal Navy ran the diving facility, and the guy in charge of the diving facility was in charge of the ship. He had pretty much a free reign to tell the craft master, "I want you to take the ship, put it here and put it in a four point moor. Then, we're going to dive." I went on at least two or three aircraft salvages while I was there. It was amazing. Even though they were only maybe in 100 or 150 feet of water, in a day or two of saturation diving, they could do as much work as it would have taken a week or more to do from bounce diving, in terms of finding the right pieces.

The upward excursion was going off pretty much without a hitch. We just did them. We had a few political bumps in the road, but we finished them up. I wrote it up, published it in *Undersea and Hyperbaric Medicine*, and it got written up in the dive manual, so the excursions got extended from 150 feet all the way to the surface. Nothing really ever became of the 75-meter tables. We just kind of did it and worked and never even knew if it ever got written up. But they seemed to be happy with the result.

The thermal garments is another story and involved using a lot of instrumentation and software that John Zumrick, while he was at NEDU that we got NEDU to basically sent the whole system over to England for six months.

INTERVIEWER: Now, was that done at pool or was it ----?

DR. THALMANN: No. We did it over at the experimental diving unit in Portsmouth,

which was across the way from Gosport. They had a cold tank there and the whole thing in ten feet of water. They also had an SDV mock-up that they could put in there. It was just the front part of it. The divers would sit in a space that was more or less equivalent to what they would be confined to in an SDV.

INTERVIEWER: The date is Friday, August 29th, and this is the second interview with Dr. Ed Thalmann. The interviewer is Dick Vann, and the location is Joe & Joe's Tavern in downtown Durham.

DR. THALMANN: We ended the last interview with the beginning of the thermal study of Gosport. You wanted to backtrack a bit and talk about where that came from, now that INTERVIEWER has figured out how to work the recorder. We had started off with a traditional Haldanean approach to decompression modeling.

INTERVIEWER: When did that occur?

DR. THALMANN: Oh, when did it occur? Well, I certainly started thinking about decompression models back in 1975 or before I went to Buffalo. I worked on them at Buffalo and really was working strictly on the Haldanean approach, trying to come up with a decompression model that would compute Navy tables. The ED reports would lead you to believe they developed such a mathematical algorithm that when the testing was finished, it would actually just print out a complete set of Navy tables. I was uniformly unsuccessful in coming up with an algorithm to do that.

I used an exponential compartment with the same half times as those in the report, pretty much the same end values as those in the report, yet was unable to come up with an algorithm to compute all the tables. It was close, but upon closer reading of

the reports, it looked like they may have adjusted some tables by hand without adjusting all the tables.

At any rate, I eventually came up with an algorithm that used exponential uptake and off gassing, much like Haldane. I came up with something called N-Val zero which, when plugged into the algorithm in exactly the same way the Navy computed its table using the same mathematical principles computed in 80 tables pretty close.

The goal was that if the table wasn't the same as in the diving manual, it had to be slightly longer. I came up with an algorithm that computed the Navy table pretty closely. Then, I went ahead and did some repetitive dives on it to see what would happen. Lo and behold, I found that the second repetitive dive on the algorithm was coming out with much less decompression than the repetitive dive groups procedure would have you do.

It didn't take long to find out the reason for that: the repetitive dive groups were based on 120-minute tissue. In fact, in the real time algorithm, very rarely did the 120-minute tissue control [unclear]. The question was whether you could really do these dives. In other words, could you do a repetitive dive that came up much, much faster than the repetitive dive procedures in the diving manual would allow? We came up with three n-value matrices, and they were the matrices that actually controlled how the decompression was done. N-Val 1 computed the first dive. The dive that I used as a benchmark was 190 for 30 with a one-hour surface interval, followed by another 190 for 30.

INTERVIEWER: Had that been tested in the original?

DR. THALMANN: The 190 through 30 had been tested, but I don't know if the repetitive dive had been tested. I can't remember. N-Val 1 kept the first 190 for 30 pretty close to what it was in the dive manual. Then, of course, the second 190 for 30 was much shorter. N-Val 3 was adjusted to keep the second 190 for 30 decompression according to what the repetitive dive procedure would require. Therefore, the first 190 for 30 was longer, and N-Val 2 split the difference between the two.

Now, we never started off testing the 190 for 30. This was just a benchmark that we used to adjust the software. We started off with, I think, a couple of hundred feters. I'd have to go back and look, but the bottom line was that it was pretty obvious that N-Vals 1 and 2 gave decompressions that were too short and caused a lot of decompression sickness. We ended up focusing on N-Val 3.

INTERVIEWER: Did you test N-Val 1 and N-Val 2 during your trials?

DR. THALMANN: We tested N-Val 1 initially, and it was rapidly discarded because of too many decompression signals. The initial testing of N-Vals 1, 2 and 3 was done while I was in Buffalo. I had, as I mentioned earlier, set everything up and turned it over to a guy named Ian Buckingham, who was a Canadian medical officer.

INTERVIEWER: Did he write that up in his report?

DR. THALMANN: It was in the first report, yes.

INTERVIEWER: Those were air dives?

DR. THALMANN: No. They weren't air dives. They were 0.7 PO<sub>2</sub> dives. We were testing them for the Mark 15. Additionally, the specification was that the deepest dive would be 175 feet. Well, that was rapidly discarded because 175 feet was an incredible amount of narcosis, so they backed off to 150 feet as the deepest depth. The series

came to a halt because they just had more decompression sickness than they knew what to do with.

The second problem was that they were using printed tables. They weren't doing it in real time. They would print out a set of tables and dive those. Then, of course, if they had ear squeezes on the way down, or if they had anything that caused them to deviate from the schedule, they always had a problem in trying to decide how to correct for it. It really wasn't a very clean series.

Just after that first series shut down or maybe shortly thereafter, I came back from Buffalo to NEDU in Panama City in 1977. After reviewing the first trial, I came to the conclusion that the only reasonable way to do the trial was to compute all of the schedules to real time. I sat down with the computer guys, and we figured out a way to do it in real time. It wasn't that hard to do, but we figured out a way to do it in real time. We had a digital depth cage hooked up to the chamber that we hooked up to the computer, and on the CRT in front of the dive supervisor's console was a display that continuously told the dive supervisor the diver's first stop depth was, which was called the 'safe ascend depth.' In other words, it answered how shallow he could safely ascend to, and then it gave the total decompression time. That worked like a champ because then, when we had problems on the way down, the computer just automatically corrected for it.

The other reason that we were happy with the situation was because the whole point was to prove that the algorithm was correct, not the tables, so by doing it in real time, we reckoned that we were also exercising the algorithm much more closely to the way it would be exercised in real life, taking into account delays in ascent and descent.

INTERVIEWER: You also had in mind a decompression computer at that time?

DR. THALMANN: When we started testing the Mark 15, from the get-go the thinking was that we were designing it for a decompression computer, because the two individuals from NOSC had come by NEDU earlier in 1974 with a proposal to build a decompression computer.

INTERVIEWER: What was NOSC?

DR. THALMANN: It was the Naval Ocean Systems Center, in Kailua, Hawaii, a Marine base. The Naval Sea Systems Command had given them the go-ahead to try to develop the hardware. The ED was going to develop the software. The whole point of the effort from the beginning was to develop an algorithm that would go into a decompression computer.

However, it was recognized that the computer hardware might take longer than the software, so we decided that in the event that the algorithm testing was finished before the computer, we would come up with a set of printed tables. We also needed a set of printed tables for emergencies anyway, but the original proposal basically indicated that we were trying to man-test a computer algorithm, not a set of tables.

We completed the first phase of testing, concentrating on these deep dives, like 150 for 30 and 120 for 30, because it was envisioned that the divers would be on submarines that had dry-deck shelters on the back. Those submarines also had Swimmer Delivery Vehicles (SDV) in them, and the divers would get into the SDVs and launch themselves from some depth. It would take about a half an hour to launch, so that would be spent at the deepest depth, which initially was going to be 120 to 150

feet. Then, they would ascend to some shallower depth, probably around 30 feet, and on the way back, they would come back into the submarine.

We spent a lot of time concentrating on these deeper dives. When we were done, we thought we had a pretty good algorithm for doing the deeper dives. When then just extrapolated the algorithm to the shallower depths. But since we hadn't tested the shallower depths, the no-decompression limit was rather short, like a sixty-foot no-D limit. It was like ten minutes, and a 60 for 60 required a five or ten-minute stop at ten feet. Well, we thought that was a reasonable trade-off and didn't make much of it until we sent it out to the fleet. They were just terribly upset. At the time, it was a no-no to do decompression dives unless you got dispensation from somebody.

Two things happened. One, you got some money to go back and look at no-D limits. Two, Bill Spaur went out, convincing the powers that be, if we were going to have a decompression computer, the decompression was obviously going to be the norm. There was no way that you could really avoid decompression diving unless you were so conservative that you hamstrung the operation.

In the second phase of the  $N_2O_2$  algorithm testing, we went back and concentrated heavily on the No-D limits. We got a set of No-D limits that were very reasonable and also fit in with the deeper decompression dives that we had done earlier. In the end, we thought it was looking pretty good.

Well, we started out, as I said, with exponential uptake and off gassing. Partway through the dive series, it became evident, especially for some of the repetitive dives, in order to get longer decompression times, the No-D limits began to shrink. We thought that was necessary because we were having too much decompression sickness

on repetitive dives. The no-D limits began to shrink because of the way the n-value matrix was set up. We couldn't reconcile with it. In other words, we couldn't keep the No-D limits, which we thought were safe, and make the repetitive dives long enough to make those safe. I had been fussing with an idea for some time about a decompression model in which immediately upon any reduction of pressure, a gas face formed.

INTERVIEWER: Now, why had you done that?

DR. THALMANN: Well, it was from the literature, which would lead you to believe this happens. It was not any great insight. I was just reading the literature.

INTERVIEWER: What was the literature that you had read for that?

DR. THALMANN: I was just reading the literature in general.

INTERVIEWER: And Hills?

DR. THALMANN: Well, that was part of it, but if you just read the dive literature in general, a lot of the thinking in it was that bubbles formed in the ascent. The other thing that was being kicked around, and there were some experiments to back it up, was the claim that during ascent, the off gassing rate slowed down much more than you would expect from an exponential off gassing. The experiment I remember in particular was one where the theory behind it was that as gas phases form, what they do is reduce the tissue tension and essentially increase solubility, so more gas is retained in the tissues at a lower tension, and it takes longer for that gas to get washed out. I made a model that had those features, and it had something called PBOVP, which meant bubble over pressure, and that would be the pressure inside the gas phase. I assume once that gas phase formed, it would be relatively constant. It just seemed

like a good bet because until you get the very, very small bubbles, surface tension effect doesn't really play a role.

INTERVIEWER: The over pressure was due to what, tissue forces?

DR. THALMANN: I didn't say to what the over pressure was due. I just said that there was an over pressure, and I imagine it was due to whatever forces cause an overpressure, tissue forces, surface tension, or whatever.

Initially, we started out with a PBOVP of zero and a set of n-values that were then fit to the no-D dives for the shallowest n-values. Those were then adjusted to give longer decompression dives to the repetitive dives we thought were unsafe. We tested them during the second phase, and they worked out pretty well. Lo and behold, we came up with the Mark 15 tables based on this asymmetrical algorithm in which the off gassing was much slower than the gas uptake.

INTERVIEWER: It was a second report on the Mark 15 testing?

DR. THALMANN: Right. That was the report with the tables that are in a dive manual. It was the second report. We took the algorithm one step further because it worked well on 0.7, and some of the revelations we had about air dives and the dive manual may not have been as accurate as we thought.

INTERVIEWER: How did you...?

DR. THALMANN: Well, the wisdom up to then dictated that what was in the dive manual was okay, which meant it didn't give a lot of decompression sickness.

INTERVIEWER: How did you come to the conclusion that that might not be so?

DR. THALMANN: I came to that conclusion because some of the predictions of the model gave longer schedules on 0.7, we thought. Some of them were actually longer

than air. We'd say, "If this air schedule is safe, this 0.7 schedule ought to be really safe." It didn't seem to be turning out that way, though. But all we had done were 0.7 dives, so we were in the position of looking at constant 0.7 PO<sub>2</sub> schedules and guessing what would happen on air.

Well, we finally turned around and did something called the 'air algorithm.' We took the Mark 15 0.7 algorithm and plugged in air, and we decided to do a bunch of air dives. Well, because of some technical difficulties, the software wasn't quite ready to go when the dive was ready to go. By that I mean that we had a bunch of divers coming into the command, NEDU, who were ready to dive. We couldn't just have them sitting around with their thumbs in their ears. I said, "Let's start off just doing some dives right out of the dive manual." Completely at random, we picked the 60 for 180 and decided to dive that on a 60 for 200 schedule because we were going to do hard-working, cold dives. That was a random choice. It was not based on anything other than getting a dive that was a couple of hours long.

We wanted something relatively long, so we did the 60 for 180. To our surprise, we had a fair amount of decompression sickness, so we adjusted the model to give a longer decompression time. I think the original decompression time was 75 minutes, and we tested a schedule that was almost twice as long and it still gave too many bends. Eventually, we ended up at like 225 minutes, and that was really the first indication that maybe the tables in the dive manual were not as safe as they should have been.

One of our assumptions was that the algorithm was predicting air schedules much longer than what was in the dive manual, or there was something wrong with the

algorithm. It began to dawn on us that maybe there wasn't so much wrong with the algorithm, but maybe the schedules in the dive manual were too short.

At any rate, we adjusted the algorithm based on the 60 for 180 to make that diver reasonably safe and then embarked on a dive series. This was called the 'air algorithm,' and we basically did air dives. We did a whole bunch of repetes, and we did No-Ds. We found we could dive No-D limits either equal to or greater than those in the Navy dive tables.

For instance, we did a bunch of 190 for 15s, which seemed quite safe, though the dive manual says 190 for five. I think we got out as far as 60 for 80 at the 60-foot dive. When we got to some of the decompression dives, the story was different. The one thing that does come to mind is that we really never were able to do 150 for 30 satisfactorily. We always got too much decompression sickness. We were able to do 100 dives okay. We did 100s for 60s, and they were okay. I think we did 120s for 30s, and those worked. When we did 150 for 30, we really were never able to get dives that worked.

Well, during the air algorithm, we not only tested air dives but went back and tested combinations of dives. For part of the profile, we'd breathe air. For another part of the profile, we'd breathe 0.7 to test the algorithm in general, and that seemed to work. At the end of the dive series, we had an algorithm that worked well on air, we thought.

Now, it was slightly different than the V-Val 18 algorithm. The difference was that we began to look at O<sub>2</sub> and the gas tanks, which gave rise to bends. It wasn't

simply the inner gas tension. It was inner gas tension plus O<sub>2</sub> tension plus the venous CO<sub>2</sub> plus the venous water vapor pressure. Those were all constant.

INTERVIEWER: How did you conclude that was the case? What led you to that?

DR. THALMANN: Well, I didn't conclude it was the case. It was certainly evidenced in England that O<sub>2</sub> played a role. There were some goat experiments that were done by...

INTERVIEWER: Those were very, very high. That was 3.5 air.

DR. THALMANN: It played a role. Also, in switching back from 0.7 to air, if you assume O<sub>2</sub> has a role, you get different predictions on the decompression schedules. Not only did we look at inert gas, but we also postulated that each tissue, the 5, 10, 20, 30-minute tissue, had a certain extraction rate. Based on that AV extraction rate or amount, you could predict what the venous oxygen tension would be for any given arterial. As the arterial oxygen tension went up, the venous oxygen tension went up a little bit, and that was actually summed into the decompression risk because the decompression risk now included O<sub>2</sub>.

The schedule and test were semi-successful, and when we came out of it, we thought we had an algorithm that wouldn't do too badly with computing air, 0.7, or being able to switch between the two. But I wasn't ready to push it as a replacement for the air tables, because we hadn't looked at things like surface decompression, which is part and parcel to the air tables and used quite extensively.

If we had just come up with a change to the air schedules without the surface decompression, it would have been unsatisfactory. I just let that slide. That was at the point that I went off to England. What I left behind was the 0.7 N<sub>2</sub>O<sub>2</sub> tables, which

were published in the dive manual, [as were] the results of the air algorithm.

Nobody at NEDU, at least none of the medical officers at the time, picked it up and pushed it, so that effort really stopped when I left. I continued over in England a bit, using it to help compute some 75-meter heliox tables.

INTERVIEWER: You had not done the heliox dives before you left?

DR. THALMANN: We did the heliox dives before I left.

INTERVIEWER: Oh, you did?

DR. THALMANN: But that was a separate effort. That was very similar to V-Val 18.

INTERVIEWER: How did you adjust the n-values and the tissues or have time when you went from nitrogen to helium? Graham's Law?

DR. THALMANN: No. It was based on what was in the dive manual, and we just plugged in some schedules and adjusted the n-values to give schedules in that ballpark. In the end, a lot of it was empirical.

INTERVIEWER: Well, how did you handle two inert gasses?

DR. THALMANN: We didn't. For the Mark 16, we had the divers do a purge at the surface whereby they exhaled as hard as they could, inhaled and did a washout to get rid of as much nitrogen as possible. We also monitored nitrogen tension during the dive. It was to an underwater habitat the divers would go, and they could actually plug a sample line into it. What we now call H-valves were just an empirical number that took all this into account as a big gemisch . That was the way we dealt with it. We didn't try at that time to get into the realm of attempting to account for nitrogen. We just assumed that everybody would start out with about the same  $PN_2$ .

The helium tables were actually finished before the air algorithm was done.

Those got published and were based on the 75-meter heliox tables for the Royal Navy EOD when I was stationed in England for two years.

At any rate, in England, we had the opportunity, as I mentioned, to finish up saturation excursion dives. The other big study we did over there was the thermal garment study for the Royal Marines, who had gotten themselves some SDVs and admitted that they really couldn't do 12-hour missions, as some of their scenarios called for, and stay warm. We did a fairly extensive thermal study, mainly with dry suits, looking at the various under and outer garments and different kinds of gloves. We used the test pool with an SDV mock-up in it. The divers went down and sat for many hours, and they were instrumented with a bunch of thermal transducers, heat flow transducers. It was a 12-point model, so each one of the transducers was at a certain anatomical position on the body, like a forearm, upper arm, thigh, back, et cetera, and the nice part was that we wanted to make modifications to the garments. They could take them over to a wet suit shop in Portsmouth and get the stuff done right off the bat. In the end, we did pretty well.

We came up with a very nice thermal garment, which was based on a rubberized outer garment, one that was fairly thin but very flexible, and a Thinsulate undergarment. I guess the main thing we did was a set of gloves. We used Thinsulate ski gloves underneath what were then sold as windsurfing gloves for windsurfers. We got very large windsurfing gloves and pulled them over the Thinsulate gloves. We made up a sealing arrangement at the wrists, and that didn't put any pressure on the wrists but kept the hands pretty warm. The Royal Marines were pretty happy with that

garment and went out and had a whole bunch of them made up. They used them for quite some time, I understand.

INTERVIEWER: Were the Royal Marines [part of] the Special Boat Section, or SBS?

DR. THALMANN: No. They were Royal Marines.

INTERVIEWER: The Special Boat Section is made of Royal Marines.

DR. THALMANN: I never got the impression they called themselves the SBS. When I left England, I left behind three things. We finished up the saturation excursion dives.

(Interruption)

DR. THALMANN: The 75-meter tables and those were actually just proposed tables. The deal was they had a big meeting over there with the Supervisor of Diving, and we decided that we didn't have to formally test them. We could field-test them, we figured. The tables were issued for use during practice diving, and the only change in their operational scenarios was that they had to have a medical officer at the dive site when they used [the tables] until they accumulated a hundred man dives. After they accumulated a hundred man dives, they would then look at the data and decide whether these profiles were okay to use in the fleet. As I understand it, they eventually accumulated a hundred man dives and decided the tables were okay.

When we got back to NMRI, I found myself in charge of the Decompression Research Group, as it were. I found, and maybe I expected it, that really nothing in decompression had progressed since I had left NEDU, at least in terms of operational procedures. One thing that had happened was that Paul Weathersby and Lou Homer had come up with this probabilistic decompression modeling technique, which they were using to incorporate large numbers of diverse dives. They also used it to compute

parameters for decompression models based on a lot of different dives. Maybe you didn't have a lot of repetitive diving under exactly the same conditions.

Looking at this while I was in England, I didn't quite understand it and when I got to NMRI I immersed myself in it to the point at which I began to understand what was going on. I will admit that in the beginning, I didn't thoroughly buy off on what they were doing, but after a while, I began to see what was going on. At the time, they were using exponential models, the typical Haldanean exponential uptake and off gassing models. Based on those models, they went in and did risk analyses of Navy tables, DCIEM tables and various and sundry other tables. They would take this exponential model and calibrate it against a bunch of man dives, of which they knew the profiles and whether somebody got bent. Once they had a good set of parameter values, they could go ahead and turn around and take any dive profile and put it through the algorithm. It would spit out a probability of bends. Basically, once they were done, they could take any profile they wanted and compute the theoretical probability of decompression sickness. They did that, as I said, for air tables, among others.

Well, looking at their effort and reflecting on the fact that at NEDU, our exponential uptake on an off gassing effort really led us into a brick wall, I injected the V-Val 18 model into it, the exponential uptake and linear off gassing model. Now, in order to convert this to a probabilistic model instead of using n-values, we used time integration, the super saturation ratio, or a ratio of tissue tension. No, it was a difference between the theoretical tissue tension and the ambient, so it was a super saturation difference, or the super saturation itself, and we said the time integral of that

somehow related to whether you got the bends. We took all the dives that we had done at NEDU and any other dives we could find and came up with a set of parameters for what became known as the LE model. Some it actually fit better than anything that had been tried previously.

Therein began the NMRI effort looking at the LE model. Now, once this happened, I began to wonder if we shouldn't go back and have another look at the air algorithm dives, those we did at NEDU that were not quite as satisfactory as we wanted. I was told that there wasn't a lot of NAVSEA interest in doing this. Well, I went down and saw Captain Chuck Bartholomew, and in the end, he agreed that we should begin pursuing a revised set of air schedules, but he didn't want to link it to a piece of hardware.

INTERVIEWER: Do you mean a piece of hardware, as in a dive computer?

DR. THALMANN: The reason he didn't want to link it was not because he didn't want a decompression computer, but he didn't want new air tables to be held up, waiting up for a decompression computer. If the tables had been ready to go before the computer, they would have done that.

He gave us the go-ahead and we wrote some routines that allowed us to actually compute the tables in real time, which was a bit more complicated because of the math. Without going into the details, there are a lot of iterative techniques involved.

INTERVIEWER: Who were the people working on this?

DR. THALMANN: There was a computer contractor names Shalane Shurvansi and a guy named Eric Parker. They were the really two main efforts at NMRI, in terms of getting the software up and running. A big dive series started out with NMRI doing

small numbers of dives to see if it would work. Basically, the idea was to see how the algorithm would work prospectively. In other words, we had gotten a set of parameter values that again would predict certain decompression sickness probabilities for certain dives. Then, we went out and dove those profiles to see how close they were and found they weren't that far off. In the end, we had something called a NMRI 93 model. The idea was to then sell this to NAVSEA.

Well, the problem with the model was that the longer dives predicted very, very long decompressions, and I had my misgivings about whether the fleet would buy off on it. It turned out they didn't. In the end, they looked at it and said, "We're not having a lot of trouble with our air dives, and we're not really interested in having these incredibly long decompression schedules when we don't think we need them."

INTERVIEWER: Well when you say 'they,' whom, specifically, do you mean?

DR. THALMANN: 'They' was the fleet.

INTERVIEWER: Yes, but who, specifically?

DR. THALMANN: Well, it wasn't anybody specific.

INTERVIEWER: Well, was it the command? Was it the master divers? Was it the rank and file divers?

DR. THALMANN: I think it was the master divers, mainly, who complained loudly to NAVSEA about it.

INTERVIEWER: What were their specific complaints?

DR. THALMANN: There weren't any specific complaints. They would say, "Hey, these things are long," and "We don't need them that long. It's going to hurt our ability

to dive.” When we went back and tried to show them that they would very rarely dive long profiles, it didn't make any difference to them.

INTERVIEWER: How about the no-stop limits? Were they happy with those?

DR. THALMANN: The no-stop limits were fine.

INTERVIEWER: They were okay with them even down to forty feet?

DR. THALMANN: I don't want to get into that too much, but the repetitive procedures turned out to be pretty complicated because of the profiles we were computing. Rather than having a procedure in which you came up from a dive, had a repetitive group and used that to calculate some amount of time you added to the bottom time of your second time, you actually came up with a repetitive group and based on the surface interval that would decay but then rather than compute residual nitrogen time or some such thing you actually picked up a new set of tables so that there were eight or ten volumes of tables.

Now, I didn't think this was a bad thing. There were more tables, but you didn't have to do any math. In the end, the fleet divers, I guess, didn't buy off on it. At any rate, the whole thing slipped to the back burner. Eventually, the Navy did turn around and let a contract to build an underwater decompression chamber. Cochran built one, and our model eventually got installed in that. The operators had some misgivings about it. If you look at some of the profiles on paper, there are some that have much longer decompressions than you would utilize for other procedures.

At any rate, this was the procedure they were using for SDV operations because they spent a lot of time shallower than thirty feet. The dive tables had no repetitive groups shallower than thirty feet. I went back to the original reports. Using the same

methodology, I computed a method by which they could get credit for being shallower than thirty feet. That allowed them to compute decompression schedules for SDV operations.

Well, they were reticent to use the SDV decompression computer because they thought that all of a sudden, they would be having a lot of decompression stops. Frank Butler, who's the SpecWar medical R&D officer, leaned on them, I guess, to put it mildly, and got them to start using the decompression computer. Now, they love it. They don't have to keep track of their dive schedules. The decompression computer does that for them, and they almost never get into decompression diving. I don't think they've ever gotten into decompression diving. They've never bent anybody. That has worked out really well.

During the time I spent in NMRI, we had done the big dive series to get to what is known as the NMRI 93 Model, which never really made it into fleet use, as far as tables, but resulted in a very powerful tool for computing the risks of bends. The reason it works one way and not the other is what I call the 'tail.' Since computers are mindless, and if you tell it to compute something to a certain level of risk, it goes out to 14 decimal places to get to that level of risk. The is done iteratively, so it starts with a short table and keeps making it longer and longer until you get to a table that the computed risk is less than what you specified, called the target risk, but it turns out the total decompression time does not increase linearly. It increases very non-linearly.

In the beginning, as you're moving from the high-risk area to the low-risk area, the TDT doesn't increase very much for each unit of risk decrease, but the time gets

longer and longer and longer. As you get near the end, to get that last two-tenths of a risk increment, you can get some pretty substantial increases of decompression time.

The decompression tail accounts for such a small risk that it doesn't make any difference if you're actually computing the risk from a profile. If you have a profile, with or without the tail, that long tail, and you just chop it and then compare the profiles, one might come out 3.5 percent and the other one 3.2 percent. We know from experience that you can't really detect that small a difference in risk without doing thousands and thousands of man dives, which we're not going to do. It turned out to be a very powerful tool for analyzing dives, but it turned out to be impractical, not inaccurate, not bad, just not practical, practical use in computing profiles because you haven't learned how to manage the tail yet.

The second reason that the probabilistic algorithm is impractical is that right now, it is mathematically complicated in the sense that you have to use iterative techniques in order to get to the correct profile. These take up a lot of computation time and it is only now that we are getting small CPUs that are both capable of doing this and will fit in hand-carried or wrist-carried instruments. The v-val 18 is deterministic, and it's dirt simple. You can program a calculator with the tables, so it's very simple mathematically.

INTERVIEWER: When you mentioned the iterative procedure to find the best table, is that defined as the shortest decompression time?

DR. THALMANN: Yes. We're getting into areas about which you could talk for hours. Basically, there are many different decompression profiles that have the same

risk because the risk is the time integral of the super saturation. What is different between these schedules is the decompression time.

You could have some schedules with very long decompressions and some schedules that have shorter decompressions, but they all have the same risk. The constraint of the algorithm is to find the shortest decompression time with that risk. That's where the iterative technique comes in. If it does a trial profile, it fairly rapidly can hone in on getting some kind of a profile that will have a risk near the target risk. The trick is to get from there to the shortest one. What it does is just keeps computing profiles that are shorter by five-minute increments. It takes the five-minute increments off either shallow, deeper or at whatever the decompression stop is and computes risk tables. By doing that iteratively, the algorithm can tell the most efficient way to either shorten or lengthen the table to get to that target risk. Then, it will figure out what the shortest decompression time is. This may become clear if I write it.

We use an NMRI 93 model quite a bit to analyze dives, but we don't use it so much to compute dives because they end up with these fairly long decompression times in some cases. From a practical standpoint, those may not be necessary. We do agree that for most air diving, decompression schedules ought to be longer than what is in the dive manual, as you get away from the no-D limits.

DR. THALMANN: We've beat the NMRI model into the ground, but we ought to talk about some other things that happened, at least during the time I was at NMRI, because that's what I know the most about.

DR. THALMANN: At NMRI, we obviously pushed the NMRI 93 Model and spent a lot of time gearing up and doing the dives associated with that model. We also did a

whole bunch of surface decompression dives on air because the perception was that the tables may not have been safe, so I just tasked the master diver to go out and use these as training profiles. That way, we didn't have to write a protocol or get IRB approval, because they were straight out of the Navy Diving Manual training dives. He picked as many different types of dives as he could, and without going into the details, he did a large number of different dives. There was no decompression sickness that I recall.

INTERVIEWER: Were these dives ever written up?

DR. THALMANN: No. But they're in the database and that's as much of a write-up as you need. All you need to know is that umpteen dives were done, and here are the profiles and the bends. A lot of them, yes, just ended up in the database and never really resulted in a formal report. I didn't see there was a need for one.

The other thing that we looked at was saturation diving and I was working on some different types of models than the V-Val 18. These were very simple-minded models that allowed you to always start saturation decompression with an upward excursion. Then, we got into the issue of how frequently you could make an upward excursion. What we tried to do was make the decompressions a lot more flexible, depending on what time of day you started. In the standard Navy parlance, you decompress at the standard saturation decompression rates, but then you don't decompress from midnight until six in the morning and from two four in the afternoon. This seemed illogical.

Well, we did change it around so that you had to take eight hours of stops, but you could basically take them any time during the day that you wanted for more

flexibility. To that, the fleet balked and really was not interested. As usual, it did so in a passive-aggressive manner, rather than just coming out and saying, "We have all of these simple procedures ground into our Ops, and it would be a Herculean task to change them. Therefore, we're not interested." They came up with all kinds of other stupid reasons as to why it wouldn't work, but I was smart enough to see the handwriting on the wall, and we just stopped.

Another project we were involved in at NMRI was looking into warm water diving, and that was a direct result of Desert Storm. Two things came out of it. Not only was it warm water diving but warm water, hundred percent oxygen diving and we needed to see whether the atropine nerve gas prophylaxis would have any undesirable effects. In other words, would it enhance O<sub>2</sub> toxicity?

We geared up and did a whole bunch of dives, hundred percent O<sub>2</sub> dives, in upwards of 94-degree water. We showed that divers, in their tee shirts and swim trunks, didn't seem to overheat. They seemed to be able to complete the profile. In the small number of dives we did, we didn't see any big effect of warm water or the nerve gas prophylaxis on oxygen convulsions.

INTERVIEWER: Did you have any symptoms or any seizures, any episodes of oxygen toxicity?

DR. THALMANN: I don't think so. I don't think we had any symptoms at all, as I recall. Tom Doubt wrote that up, and it's in a NMRI report. I don't have the report at my fingertips, I'm afraid. Anything else we got involved in was with thermal issues, and those were the same old bugaboos. It seemed that there were garments that could keep a diver's core temperature above some predetermined minimum, but the problem

got to be their hands and feet, so we did a preliminary study in which we just warmed their hands using electrically heated gloves. We got some ammunition handlers' gloves that are used by NATO troops.

INTERVIEWER: Was that in cold water?

DR. THALMANN: Yes. We showed that something in the area of five or ten watts might be enough to keep a diver's hands warm. That seemed like a reasonable amount of energy a diver could carry on his weight belt, but we never were really able to pursue that to its logical conclusion.

I recall a couple of other things at NMRI that I engineered. I convinced Andrea Harriman to have a look at all of the human options in exposure data, going way back to Donald's experiments. She did eventually get all of that coded and into some computer files, which provided an incredible database for hundred percent oxygen diving. Of course, she was unable to use this to develop her oxygen toxicity model. In theory, it's there for anybody to use to develop their oxygen toxicity model.

To wrap up, one of the problems that NMRI was having had to do with a lot of animal data funded, which didn't really seem to make it outside the realm of interesting, scientific publication. I sat down with Drew Dutka and said that a consensus had been developing among the diving medical types that having to initially crash through 165 feet for a gas embolism was probably unnecessary in that it was more reasonable to go to 60 feet and observe the patient's response. Then, you could determine what the pressure profile should be after that, and he did get together to do enough animal experiments to bring that to some kind of reasonable statistical significance. That led us being able to get not only a consensus among diving medical

officers but some animal studies that backed it up. We eventually got some data to back up the fact that going to 60 feet was reasonable. When it didn't seem detrimental, we'd go to 60 feet first and then to 165 if necessary. If symptoms got better at 60 feet, we went ahead and just treated it at 60 feet.

INTERVIEWER: Was that a NMRI report or was that published?

DR. THALMANN: I'm going to say it was published in the literature eventually.

McDermott, I think, was the guy who actually did the work. He was a graduate student at NMRI. That's about all I can think of for now.

(Whereupon, the PROCEEDINGS were adjourned.)

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

INTERVIEW OF  
CHIEF ENGINEMAN FRED LIEDER

Kensington, Maryland  
Friday, September 5, 2003

## PROCEEDINGS

INTERVIEWER: You're an EOD technician?

CHIEF ENGINEMAN LIEDER: Yes.

INTERVIEWER: How long have you been an EOD tech?

CHIEF ENGINEMAN LIEDER: I've been an EOD assistant since 1989. That would be 14 years.

INTERVIEWER: What other assignments have you had?

CHIEF ENGINEMAN LIEDER: When I first came in as an EOD assistant, I was stationed at MOB Unit 4 at Key West, training Mark 7 marine mammals. Then, I went to EOD school and from there to MOB Unit 5 out in Guam. Then, I worked in STILO detective in Indian Head, Maryland. Then, I went to MOB Unit 3 and then moved to Naval Special Clearance Team One.

INTERVIEWER: You've been here about a year?

CHIEF ENGINEMAN LIEDER: It's been one year, almost exactly.

INTERVIEWER: During Operation Iraqi Freedom, what was your job?

CHIEF ENGINEMAN LIEDER: I was the leading chief petty officer for both Mark 4 and Mark 7 marine mammal systems.

INTERVIEWER: Now, what are those?

CHIEF ENGINEMAN LIEDER: Mark 7 is a mine hunting capability that detects mines, usually bottom mines or buried mines. Mark 4 is a mine finding marine mammal system that locates moored objects in water columns at various depths.

INTERVIEWER: They both use Atlantic bottlenose dolphins, correct?

CHIEF ENGINEMAN LIEDER: They both use Atlantic bottlenose dolphins, yes.

INTERVIEWER: Tell me about your deployment to Iraq.

CHIEF ENGINEMAN LIEDER: I showed up in September of last year. At that time, we had gotten the word that we were most likely going to be participating in the war. They wanted a marine mammal system to clear harbors was what we were told. Mark 7 fit that bill exactly. We

were, at that time, just planning, and we thought we might leave as soon as December or January. We were a long way from being ready for that, equipment-wise, and with our training of personnel. We decided to sit down at my office and figure out how the heck we were going to do it. We came up with the idea of changing our whole tactic. We usually operate a large hard hull boat, 22-foot Boston Whalers and other stuff. We decided to switch so as to be more mobile, and we went to rubber boats. We used the Mark 6 inflatable, which is slightly larger than a Mark 5 inflatable, to be our transport boat for our systems. We chose our Mark 5 boat to be our control boat for the animal, in the minefield. It worked out well. We changed our whole footprint size, from very large to very small. We also started conducting harbor clearance operations in shallower water, with multiple targets and poor bottoms to try to prepare the systems for operating in that environment.

INTERVIEWER: How hard is it to train the mammals to do something different than to what they are normally accustomed?

CHIEF ENGINEMAN LIEDER: Well, they are accustomed to doing harbors. Mark 7 can do harbors. It was kind of in their plan when they first started. But they hadn't practiced it in a while. Basically, you can look at a carpet on the floor, and if you put a chair on the middle of it, you are going to be able to see that chair. It's the same thing for the animals. If it's a sandy bottom, and you put a mine out in the middle of that sandy bottom, it's very easy for them to see it. Take that same thing, put it into mud and sink it to where it is halfway buried, with a lot of trash floating around, which we all know is in harbors, trash cans and metal chunks that have fallen over the side or wheat bags or whatever. The animal has to go through and decide what is a mine and what is not, and then report that back to us.

INTERVIEWER: Can the animals discriminate, or do they pretty much mark anything that's shaped like a mine, or anything that's about the right size?

CHIEF ENGINEMAN LIEDER: It is going to mark mine-like objects. An object has to have certain criteria for the animal to mark it and we maintain those behaviors. Now, there are false positives, but very few. Of 2,000 search stations that we did in Iraq, for example, we laid 16. Of

those, 12 were verified as non-mines. The four were buried items that they couldn't find. In less than one percent of the area that they searched they reported stuff that were not mine-like objects. That was not too bad.

We did a lot of work on that. We actually had two exercises between the time I got here and the time we left. During those, the first time didn't go very well. We were using a different set of equipment for marking mines than on normal exercises. We came to the issues there. We swapped back to our original equipment, thinking it would work just with some modifications. In the second exercise, we did tremendously well, with a 93 percent allocation. We missed one mine that we were looking for, out of all of them. That was pretty good.

Then, we deployed in March and flew over there. Normally, what we do is when we land, we take the systems with the animals and we put them into a Miller pen. The pen is a twenty by twenty-foot square pen, and twenty feet deep. We can put it together and inflate the outside, and the net hangs down twenty feet. The animals kind of get used to being in the environment for that. It's usually seven to ten days that we ask for.

For this war, we were not able to do that. Basically, what happened was that they flew thirty hours out of the water. They fly in these big bathtubs, for people who don't know, and they land in a stretcher. The bathtub is about half full of water. We keep them wet the whole time, but they are not swimming in water. For them, it is a little more stressful than being in open water.

We got there and we were supposed to put them in the Miller pen, but that was all kyboshed before we left. They wanted to keep it on the down low, and we needed to get to the North Arabian Gulf as soon as possible so that we could get into the war because our flights were delayed three weeks. We weren't able to do that.

We went straight from the plane to a truck in the pools on board the USS *Gunston Hall*. It's called a 'ship forward deploy pool.' It's three inflatable rings stacked on top of each other. They are smaller as they go up. They wedge inside of each other. There's a whole bunch of straps that hold them together. Then, a liner is put in there and we fill that up with water and it's

a pool. It has a cover over it so that people can't drop stuff on them and things like that, and it gives them shade from the lights.

We put them in there, which was the first time we have ever had to do that. Basically, they stayed in a pool environment. By the time they actually got back to a pen, it had been 37 days, and that was the first operational use, but even for an exercise, it was the longest we had ever had them in a pool and it worked very well, actually. We went on board those pools and then went to the North Arabian Gulf, where we were 32 miles off Kuwait. It was our first time putting them in the water, so we didn't know if they were going to run away, come back, work well, or what they were going to do.

We have is this IDP, which is an intermediate deployable pool, I think. I'll have to look that one up. Basically, it's a ring, one of the rings from of the pool, but it has a net that hangs off of it, so it floats on the surface of the water. You can re-beach in and out of there, which just means we can put the animal in the water and they come back in the boat. Then, we knew we had control. Yes, they were with us and they weren't going to run away.

Then, we took them out into the open water that day, if they showed us that commitment. We took them out in the open water and we worked them on a simulator mine and stuff like that, just to see how their control was. It turned out that of the five systems that Mark 7 brought and five animals that Mark 7 brought, four were up and running within about a four or five day period. They were one hundred percent, luckily, because it was on day nine, I want to say, that we got the call telling us that we were going into the Port of Umm Qasr.

What we did was put in food and equipment first, pools, our rubber boats that we had to build up, life support equipment for the marine mammals, food for the marine mammals, and personnel. We built up three pools. They were different. They looked like an above ground pool that you have at home. We built up three of those inside of a warehouse right off of Pier 2 there, which is all the way down the bottom of the set of piers. There is one through ten. The new port is ten through twenty, or something like that.

We were on Pier 2, which was secure, supposedly. We flew in while it was still kind of hot in the new port. Umm Qasr is divided into two ports. There's the old port and the new port. The old port was secure. The new port still had gunfire going on. But we flew into the old port with the Hassidic MH-53s and set up three pools.

Then, we got in our boats on the next day after we filled the pools and had everything. We had to borrow some fire hose from the Iraqi people to make it happen, because the distance was greater than we ever thought it was going to be from the water to the warehouse. We filled up the pools and got them treated and shocked, just like we do at home.

Then, we got the animals. Two of the systems came in and started working the next morning. So, it was actually about day two and a half when we started working. We had a bad storm. We were supposed to work the night they came in, but we had a terrible storm with forty knot winds and we couldn't get the boats out.

We also borrowed a box loader. If anybody doesn't know what that is, it's like a humungous forklift that holds Conex boxes. One of the Iraqis was nice enough to leave the keys in for us. Because of the 18-foot tide and lack of boat ramps, we were able to use our lifting slings to lower the boats right over the side, and also the systems, the animals, into the boats.

We were required by the President of the United States to clear Pier 5 as quickly as possible. That was for what we used the marine mammals. Mark 7 was declared what they call the 'mine burial zone.' Because it was a silty, soft mud that varied in length off of the sea wall, depending on where you were in the port, we had various lengths that we had to clear away. Then, mine hunters and UUV took care of the actually proud type contacts.

If there was something that was out of the normal, they would use us to go and just re-verify for the second check, to see if it was a popular native in the system, but we weren't really used for the proud area. That was the old port that was a mine burial zone.

The new port was 2.37 miles long and about an average of 500 yards wide. We had to do the entire port because it was just a silty area. We were there, in the old port and the new, for 19 days. We did something like 1560 waypoints, and we did them with basically three systems

because Takoma, the second male that we brought in, decided to run away. He didn't actually run. He kind of drifted away from us when we had a gas attack, so we all went running in to get our gas masks on. Well, we had our gas masks, but we had to put on all our chemical gear. By the time we got back out, after we found out it was a hoax, he was nowhere to be found.

INTERVIEWER: Which animal was that?

CHIEF ENGINEMAN LIEDER: It was Takoma. We spent time the next day, if we weren't working a system to clear a field, hunting for Takoma. A day and a half later he came back to us. We were out working one night and he swam right up to us. It was a bright, glowing body through the water. His whole outline was just glowing from the bioluminescence. It was quite pretty. I wish I'd had my camera to take a picture of it. But he came back to us.

INTERVIEWER: They normally do, right?

CHIEF ENGINEMAN LIEDER: Yes. Normally, they'll come back.

INTERVIEWER: They go UA and come back after a couple of days.

CHIEF ENGINEMAN LIEDER: We try to maintain them in the area. We use recalls and different things like that to try to keep them in the area. With dealing with this harbor, like I said, there was an 18-foot tidal difference. We were also dealing with a four-knot current when it was fully kicking, and the systems were able to work through that.

We were wondering if he would swim with the current out to sea or swim with the current upriver farther. So, it was quite an extensive zone that we had to search. He ended up being a hundred yards away from where we left him. He tried to hide. Macay is our oldest animal. He's currently 34 years old and has been with the program roughly thirty years. They found him when he was around four or five, they say. They guess. They don't know the exact age. He was a captured animal. I worked with him in Key West, back in the late 1980s, early 1990s.

Of those 1500 sonar waypoints, Macay himself did roughly, I would say, eighty percent of that area. Every day, you went to take him out and he did exactly his two or three hours a day out there, hunting his lanes. He got a little slower. All the systems got slower as we went through. Like I said, that was the longest pool time we had ever had. So, it was good to see how hard you

could push him and the different things you could do to keep his energy. When you think about it, your taking an animal that's used to echo-locating off of everything, and you put him inside of a pool. He can't echo-locate off of anything other than the other animal that's in there with him, you know, to get any entertainment. So, we spent a lot of time with the guys in the water with them, keeping them motivated and things like that. We made sure that they got out every day. That seemed to be the key to keeping them okay. We were basically in that port for 19 days. Well, there were two ports in 19 days.

Then, we flew them all back to Kuwait. When they flew in and out we used their beaching mat, which is a gray, gym-like pad that falls over them so that they couldn't fall out. We flew two of them in a 53, side by side, and just lifted them out when we got to the other end. They went to Kuwait and got six days off in the pen. Then, we tried something new. We put them onto a LCU, put one of the shipboard pools, a smaller version of the shipboard pool, on the back of an LCU, loaded our two Mark 5s on there, our little inflatable boats. All our people slept on deck. It kind of looked like the *African Queen* going up and down the river. But it had all these covers on it to keep us out of the sun because it was really hot.

We went back up the river, past Umm Qasr. It was the Kaa River. We went past Umm Qasr another 12 miles to the port of Az Zubair, which is another deep port that they use. The conditions were terrible. We had a tremendous amount of mud and a tremendous amount of oil. They had drifting nets that were coming down on us all the time, like fishermen, and big piles of bamboo. I didn't know where in the desert they got bamboo, but it just came flying down the river at four knots. You were driving this lane on your little boat, driving off of a computer screen, trying to keep on line. You just got the warning, "Hey, bamboo." You had to go around and get back on track again and things like that.

INTERVIEWER: Were you worried about the safety of the animals then, with the contaminant in the water and the obstacles?

CHIEF ENGINEMAN LIEDER: Yes. We had light oil contamination in Umm Qasr. But basically, the vets, and we travel with a veterinarian, told us that as long as we cleaned them off,

they'd be perfectly fine. We had soap to clean them off after every comeback. We didn't have to really do anything in Umm Qasr. They would have a little bit on their control surfaces. When I say 'control surfaces,' I mean their pectorals, dorsals and gluts, which are the tails. They had a little bit and we just cleaned that off. It wasn't a major deal.

When we got to Az Zubair, on the other hand, it was all over them. It was on the control surfaces, the rostrums, which are their noses, all the way up their foreheads, and on their backs. It was nothing that was hurting them, and we would clean them off as soon as they came back. It didn't seem to affect them at all in their performance. They worked tremendously well. They were quite resilient to just about everything in the water. It was amazing to see. We were very concerned, personally. We didn't want to hurt the animals for any reason other than, you know, if we had to save human life. But we were concerned about their safety. We got there and started working. It cleaned right off. We had an eye cleanser, just in case there was some in their eyes. Everything seemed to work fine.

We brought Macay and Spetsnaz, which is our other male, not Tacoma. They did that port. Only two animals did that port because it was smaller. It was about 500 waypoints every day. Again, going out to the mine burial zone was what we had or were tasked with. We didn't find a single thing in that port. It was good. The animals were tremendously better the second time around. Once they got those six days off, they were super fast.

INTERVIEWER: Do some animals work better than others? I mean, do they have personalities?

CHIEF ENGINEMAN LIEDER: Sure, they do have personalities. Some systems will have beaching issues, or coming in and out of the boat. But when you get them into the field, they work like champs. So, there are just little things, and they change. There are set patterns that you can see. There are also times we have to ask, "Why won't he beach today? That doesn't make sense," or "Why is he not finding the calibration target when we're only thirty yards away and he should be finding at fifty? What's up?"

Those are decisions we have to make out there, while we are doing it, like whether an animal is safe to bring into the field. We don't want to go through a field with an animal and say,

“Yeah, it’s clear,” when there’s a mine sitting in the middle of it and a ship blows up when it pulls in with humanitarian aid. That’s just something we don’t need. There are patterns for each of the systems. There are set patterns but they will have off days in there. There is always correction. I don’t have any children, but I would say it’s like working with children, except that all your answers are ‘yes’ and ‘no.’ You can’t say, “Okay, go and pick that tree out or pick that stick out and put it over there next to that rock.” You can’t tell them that. They have to figure out they are going to go do it and then you either say, “Yeah, that was good,” and feed them, or “No, that’s not what we want.” It’s a little harder. Try to train your dog with a clicker. Maybe ‘yes’ is one click and ‘no’ is two clicks. Tell him to do stuff. We are talking about a chain of behaviors that is 12 or 15 steps per signal. It is not something easily learned, so there can always be a breakdown here and there.

INTERVIEWER: How long does it normally take to train an animal?

CHIEF ENGINEMAN LIEDER: Right now, they are up to Mark 7, which is the most complicated of the marine mammals. It is roughly eight years now.

INTERVIEWER: Wow.

CHIEF ENGINEMAN LIEDER: It used to be a lot shorter. Now, we have added a lot more behaviors to them and the Navy was really short on animals, so they trained them as fast as they could to get them to us. We found issues with that. We would have control problems or not the best detection. Now, they keep them longer at SPAWAR before they get them to us, so we get a better product in the end.

INTERVIEWER: Is this your second time as a mammal handler?

CHIEF ENGINEMAN LIEDER: Well, now, I’m more managerial. I don’t really get to put my hands on. Now, I deal with more program stuff, especially since currently, I’m filling an officer in charge billet and we’ve combined all the mammal systems into one. It used to be that Mark 4 and Mark 7 was one group. Mark 8 was another group. Now, Mark 4, Mark 7 and Mark 8 all belong to me. We’re trying to combine Mark 7 and Mark 8 to do the same job because they are so close to each other. They work in different ranges, that’s all.

INTERVIEWER: Do animals ever get cross-trained, like a Mark 7 animal becomes a Mark 8 or a Mark 6 becomes a Mark 7? Do they always stay one thing, for their whole life cycle?

CHIEF ENGINEMAN LIEDER: What it comes down to is the needs of the Navy I think that in Mark 8, right now, we have one animal that used to be a Mark 6 animal, which is an anti-swimmer dolphin. Most of the other three Mark 8 animals were prior Mark 7 animals that we had. We used to have two depths of Mark 7 animals, which means we had four each. Now, we only have one. We gave four back to SPAWAR to maintain. They went ahead and took some of those and made them into Mark 8 animals, because it's easier to train Mark 7 to Mark 8 than it is Mark 8 to Mark 7, which was a new program.

INTERVIEWER: You dive with the mammals also, right, to verify that they are performing?

CHIEF ENGINEMAN LIEDER: Yes. I didn't go to the personnel side of this whole thing, did I? Basically, for the war we took 19 personnel from my division. Of that, three of us were EOD techs and the other 16 were either SCUBA divers or second class divers. All the divers, but not the EOD part, were the marine mammal handlers. They were the guys that were out there, handling the animals every day. They also set up a SCUBA diving office to check marks, to make sure that the training was going correctly and they did dive in the North Arabian Gulf, to verify marks, while we were getting ready to go into Iraq. Actually, I think we did get two SCUBA divers to dive in Iraq in order to locate one of our lost markers, out in the middle of the thing. They were actually two second-class divers. They were pretty happy. They got a 2544 that said they were to dive in Iraq. It kind of psyched them up.

With the EOD techs, because the animals could lay explosives, our main job was the safety of the explosives, and stuff like that. We did not use explosives during this war. We just laid markers that had acoustic beacons on them. They talk to the boat and tell us exactly where a monitored object was. Divers would go down later and check those, to see what was there.

INTERVIEWER: In the end, you didn't actually find any mines. You were able to verify that the port was clear, right?

CHIEF ENGINEMAN LIEDER: That's right. We had four contacts from Mark 7 that were nothing found on the surface by a diver, which meant that of those four marks, we had a buried mine, or something mine-like, just buried. The commander decided to place charges and blow there, just in case. That way, we considered it taken care of. That was how the system worked out. We used the mammals to mark, and we used the divers, since the animals were more time consuming than we were, to verify and take care of those.

Now, if we had found a mine, I think the plan might have changed. Instead of hazarding a diver, the marine mammal was definitely low MEU. The shape that he places is definitely low MEU, so why not send them in instead of taking the chance a whole dive team might go up by mistake? Reducing human casualties is definitely a plus. But the animals did very well. We went over with nine animals altogether, five Mark 7s and four Mark 8s. I haven't talked about Mark 8. I wasn't working with them, but they were placed in Kuwait, just in case they were needed for some sort of amphibious assault on a beach. Their job is the VSW field, the very shallow water area. They weren't needed, so they got a vacation in Kuwait, unfortunately. They were probably not too happy about it.

INTERVIEWER: Are there any other topics that we ought to talk about, or something else you want to add that I didn't think to ask you?

CHIEF ENGINEMAN LIEDER: No. It was just great to be part of the first operational deployment of the marine mammal systems.

INTERVIEWER: It was successful?

CHIEF ENGINEMAN LIEDER: It was, for mine hunting. Of course, we had the anti-swimmers for the Vietnam War. But for mine hunting, yes, it was great. It was a great tool. There is no other system in the Navy for buried mines, yet. The admirals have seen that and they were very happy to bring this over and do it. It turned out really well. I know everybody thinks there are a lot of logistical headaches going along with marine mammals, but it turned out well. I don't think the admirals ever really heard anything that I know of that would make them not call us again.

It's good to see something the U.S. people have paid so much money for be used in a real operation, and it worked so well.

INTERVIEWER: Great. Thank you very much.

\* \* \* \* \*

**CAPTAIN DESTEFANO:** Good afternoon. I'm Captain Rob DeStefano. I'm here to talk about organizing Navy divers for global rapid response and, in the process, to tell you a little bit about what Navy EOD Groups can and are doing.

I have -- that's on the first slide. I have a lot to say, I have 20 minutes to say it. So at times, I'm going to speak quickly.

While the file is loading. What you're going to see in a moment is a very condensed Navy EOD Group Mission Statement.

There are two EOD Groups, cleverly named One and Two. One is located in Coronado, California, and the other in Little Creek, Virginia. Each is composed of seven subordinate commands: Three EOD units that are active duty, and two that are Naval Reserve Force, a Mobile Diving and Salvage Unit, and a Training and Evaluation Unit.

### Mission

Provide combat ready EOD and Diving & Salvage forces to the Fleet that...

- Eliminate ordnance hazards that jeopardize operations conducted in support of the national military strategy.
- Clear harbors and approaches of obstacles.
- Salvage/recover ships, aircraft and weapons lost or damaged in peacetime or combat.

...enable maneuver

EOD Group One also fields a very shallow water mine countermeasures capability. Now, Navy EOD is a relative newcomer. Here we go. Navy EOD is a newcomer to the very shallow water MCM business.

In 1997, that's 4 years ago, we established a VSW MCM detachment composed of EOD divers, SEALs, Recon Marines, a Marine Mammal Platoon, and Underwater Autonomous Vehicles.

This warfighting lab is developing and evaluating VSW tactics, techniques, procedures and equipment for use in a very demanding underwater environment.

The predecessors of today's Joint Service EOD programs were established during World War II by then-Navy Lieutenants O.D. Waters and Draper Kauffman. The mine disposal and bomb disposal schools they founded, were later consolidated into today's, and evolved into the present-day Naval School for Explosive Ordnance Disposal that's located at Eglin Air Force Base in Florida.

EOD officers and enlisted train together, qualify to identical standards, and wear the same breast insignia. And I suspect from yesterday's SEAL history lesson, that that is another legacy of Draper Kauffmann.

Today's Mobile Diving and Salvage units are the operational descendants of Vietnam-era harbor clearance units. But I believe -- and this is my opinion -- that they're the philosophical

descendants of Swede Momsen's Experimental Diving Unit as it was portrayed in The Terrible Hours.

I don't mean this in the sense of the things that they do, but the innovative ways in which they do them. And I will try to convince you of that a little later on.

Our missions include unexploded explosive ordnance response on land and underwater, underwater mine countermeasures, salvage, damage control and repair, VIP protection in support of the United States Secret Service and Department of State, humanitarian de-mining operations, and environmental remediation support.

We routinely deploy in carrier battle groups, amphibious ready groups, and military sealift command TATFs. We respond to emergent tasks from major salvage and EOD operations through underwater inspection and recovery.

We frequently use our recompression chambers to treat civilian diving injuries, aviation-related decompression sickness, and for other medical treatments that require hyperbaric oxygen.

Here you see one of our transportable recompression chamber systems being loaded into a salvage vessel of opportunity. Our detachments can be containerized, as you can see, or break bulk configured, and admin or operationally loaded as required. All detachments are air-liftable complete.

All our surface supplied diving capability resides in the two MDSUs, Mobile Diving and Salvage Units. This slide shows their operational limits, and some examples of what they can do.

Each Mobile Diving and Salvage detachment, which are the deployable elements of the MDSUs, has its own surface-supplied air system. Each MDSU -- the parent command also has one HeO2 system, the flyaway mixed-gas dive system that you've heard about, that can be deployed with or in support of any detachment when deep dives are required.

This slide depicts EOD detachment capabilities. An EOD dive is half the size of a Mobile Diving and Salvage detachment, but all EOD divers

are trained to dive surface supplied, and can integrated with MDSUs when necessary.

The Mark 16 is a closed-circuit, very low magnetic and acoustic signature underwater breathing apparatus that we use for decompression scuba diving to 200 feet. It's used primarily in support of EOD mine countermeasures under the sea.

Typical EOD operations involve ordnance. Several of these photos are of ordnance actually deployed against the United States and Coalition Forces in anger. The one in the lower right hand

corner, is a reminder that we also operate ashore.

The goal of any EOD operation is to avoid this, or to have it occur at a time and place of our choosing.

Deep-sea HeO2 diving is alive and well. The wreck of the *USS Monitor* is located at a depth of 240 feet. MDSU-Two has been the military lead for planning and execution of two past and one upcoming expeditions in support of Naval Historical Society

efforts to stabilize the wreck and recover artifacts.

In addition to the public relations and archaeological value of these expeditions, we've also used them as opportunities to test and evaluate new procedures, such as underwater grouting which was used to stabilize the wreck.

We also validated our newest HeO2 decompression tables,

which we used operationally for the first time during the 2000 expedition. In 2001, we're planning to try out a portable saturation diving system presently used for commercial diving operations that, if satisfactory, could extend MDSU depth and duration capabilities well beyond the current HeO2 limits.

In September 2000, *U.S.S. La Moure County* grounded off the coast of Chile, suffering extensive hull damage. A MDSU-2 detachment, 19 personnel,

responded by air from Norfolk. It took 48 hours to get them to the ship.

Here you see divers mixing concrete to use underwater for patching leaks in a manner similar to what we did just a few months before, during the *Monitor* 2000 expedition.

In October 2000, USS *Cole* was attacked by terrorists. EOD divers who were in Yemen, conducting humanitarian de-mining operations, responded within hours, and were quickly reinforced by additional EOD divers who were in Bahrain on other duties.

These were EOD detachments from both EOD groups One and Two, because our areas of responsibility overlap in 5th Fleet. When it became necessary to dive inside the flooded compartments in the ship, MDSU-Two Det Alpha was redeployed to 5th Fleet from the *USNS Mohawk*, a TATF then underway in the Med. That's a 6th Fleet to 5th Fleet inter-theater redeployment on the fly.

Three-quarters of Det Alpha debarked in Bari, Italy, moved overland to an airhead with their portable surface supplied equipment, and were on dive station in Aden within 48 hours. We left four folks behind, so that the *Mohawk* retained a diving capability. Det Alpha subsequently recovered all of our fallen shipmates from *Cole*'s flooded spaces.

Over a year before, in February '99, EOD Mobile Unit 2 and SIMA (Shore Intermediate Maintenance Activity) Norfolk collaborated on surface supplied diving operations pierside inside the *USS Radford*. They removed 5-inch 54 projectiles and powders from the forward magazine that had been flooded in a collision at sea.

On 23 August 2000, at about 1930 hours -- that's just about dark -- Gulf Air Flight 72 crashed in 4 to 12 feet of sea water near Bahrain and about 6 miles from where the *USS George Washington* was anchored.

From 23 to 27 August, EOD Mobile Unit Two's *George Washington* Battle Group Detachment, an EOD Mobile Unit Six Mine Countermeasures Detachment deployed to the Gulf on other duties, and EOD Mobile Unit Eight Shore Detachment Bahrain -- three different kinds of detachments -- conducted surface swims, free diving, swimmers in a line, and scuba diving operations during which they recovered both black boxes, NTSB-designated debris, took underwater photos for NTSB, recovered a Department of State courier pouch containing classified material, and helped to recover the remains of all 143 casualties of the crash.

Lake Garda is a deep Alpine lake in northern Italy. During the Kosovo air campaign, an Air Force F-15 with an in-flight emergency jettisoned ordnance into the lake, which is a recreation and tourist destination.

EOD Mobile Unit Eight responded to both Lake Garda and to the northern Adriatic, where other pickled ordnance was being unwillingly retrieved by commercial fishermen, some of whom were injured by exploding bomblets.

Lake Garda involved high-altitude decompression diving, which presents some unique challenges with respect to dive planning and execution. The three detachments -- three different kinds, all from Mobile Unit Eight -- responded: an EOD detachment; a flyaway recompression chamber detachment, which is manned by diving medical technicians, a master diver, and some other fleet divers; and a sidescan sonar detachment. EOD Mobile Unit Eight also deployed their diving medical officer to this particular operation, because of the nature of it.

So far, you've seen deep sea, shallow water, in-ship and high-altitude diving ops. During Joint Forge, EOD Mobile Unit Eight made dives in the Sava River to recover mines and other ordnance. These photos show divers in the water, mines under the water, divers

slogging through mud, a potpourri of recovered weapons and munitions, and divers standing sentry for self-defense and security. Sometimes, people shoot at us, even when we're trying to help them.

In March 2000, MDSU-Two conducted operations for the EPA that involved this derelict asphalt barge in New Orleans. It had been in this pristine wildlife area for 30 years, and was an EPA Superfund target.

They surveyed, stabilized, and refloated the barge so it could be moved to a place where it no longer threatened the environment. You can see our divers here wading in asphalt, diving in mud, and having a generally great Navy diver day. And I think that you can see the unifying theme in Navy diving today, as in the past, is mud.

In February of 2000, the floating dry dock Sustain, which you saw earlier during Bert Marsh's presentation, broke free of a tow ship off the Virginia capes during a winter storm. She was adrift for 4 days, underway, not making way, at 4 knots.

MDSU-Two and SIMA Mayport divers helped recapture the tow and bring her to Bermuda, where MDSU-Two divers re-rigged her. From there, she completed her tow to Florida uneventfully.

This operation involved 1 percent scuba diving, and 99 percent rigging. And as you know, involved Mobile Diving and Salvage Unit Two divers, SIMA, NAVSEA civilians, and contractors.

When I was a young Navy diver, we often spent days or weeks looking for things underwater. Often, even usually, we spent more time searching for things than actually diving on them.

Sidescan sonar detachments find things. These small, easily deployable active duty and Naval Reserve operated sonar detachments contain no divers, but they optimize the utilization of our divers. Here

you see some ASD hardware and sidescan images. These systems can be deployed from any suitable vessel of opportunity.

In the lower right hand corner, is a photo of a Marine Mammal System element. These biological sonars are also used to find things. All our Marine Mammal Systems are organized under EOD Group One.

Operating increasingly outside the lifelines of ships, we use this Naval Reserve mobile communications capability to maintain connectivity with other Naval, joint, and coalition forces on the battlefield.

MCDs provide full-spectrum connectivity, including GCCS interface -- that's Global Command and Control System-- for Navy divers in the field.

We have one prototype Combat Service Support Detachment that will formally achieve initial operating capability in FY02. Yes, those are Port-a-Potties that you see there. And believe me, when you're in the field, in the middle of nowhere, with 100 divers and support personnel, and you don't have these, you'll wish you did.

Again, operating increasingly outside the lifelines, we sometimes need basic hotel services that are taken for granted when we're embarked in Naval vessels. Without this limited field service support capability, diver productivity rapidly diminishes when operating in remote or unimproved locations, or on battlefields, where elementary infrastructure, like running water and sanitation are inadequate or totally absent.

### Takeaways...

- Dive Ops Involve More than Diving
  - Logistics
  - Field/Combat Service Support
  - C4ISR
  - Side Scan Sonar Operations
  - Self Defense
- Navy Divers Do More than Dive
  - Diving is transportation to and from the workplace
  - Operate, Move, Shoot, Communicate

This slide is the punchline. If you haven't already guessed, diving operations involve much more than just diving. Topping my short list is logistics. We operate more and more outside the lifelines of support ships. The frequency, duration, and magnitude of these off-ship operations are increasing. Consequently, we've had to think about things that rarely concerned us 15 years ago -- things like communications, heads and beds, hot meals and showers in the field, minor vehicle and boat repairs, and self-defense -- things taken for granted when

embarked, but that we must be prepared to bring with us when required.

Navy divers still dive in deep water, on and inside the flooded compartments of ships, but also in Alpine lakes, in rivers and in bayous -- wherever the work maybe.

We use everything from surface supplied to HeO<sub>2</sub>, to snorkels. But diving is just transportation to the place where we employ our real skills. Just like we must be able to dive, we must also be able to deploy and redeploy quickly--to move, shoot, and communicate on any battlefield.

Organizing for Global Rapid Response means organizing for speed. At one time, rapid response was measured in weeks or even months. Today it's measured in days and even hours.

My rule of thumb, and our measure of effectiveness, is to be on station, airlift and weather permitting, within 48 hours of receiving a deployment order.

The operational imperative for rapid response simply means that sometimes waiting for help is not an option in an emergency.

### Takeaways...

♦ Organizing Navy Divers for Global Rapid Response means:

- Strategic Mobility (Speed)
  - 48 Hour Rule of Thumb
  - Operational Imperative
  - Speed of News
- Agility
  - Cole re-deployment
- Flexibility
  - Tailorable/Layerable
  - Maritime, Expeditionary, Joint & SOC
- Sustainment

The news media are ubiquitous and unrelenting in their coverage and analysis of military operations. Media relations are not the primary motivation for rapid response, but have become increasingly important.

Now this is an apples-and-oranges comparison, but consider this. The Russian response to the *Kursk* tragedy was panned in the press, or at least by some in the press as slow and inadequate. In counterpoint, the virtual total absence of press comment on the Navy diving aspects of our response to the Cole bombing was, for me, a success story.

To be unnoticed and uncriticized in today's news market is a very good thing. More to the point, the next of kin of those who died in the Cole were entitled to as much consolation and closure as our recovery efforts could expeditiously deliver.

By agility, I mean wherever they're deployed, and whatever they're doing, our detachments can quickly shift gears when necessary.

Flexibility. The basic elements of EOD Group Force Structure are detachments. These detachments are distributed globally, for initial rapid response. They can be tailored for specific missions, making them lighter and easier to move. And when more is needed, they can be layered to produce different mixes of capabilities, as you've seen.

In traditional military jargon, this is called economy of force -- being strong in the right place at the right time.

The Navy is maritime, expeditionary, and joint. So are we. We also have Special Forces customers for our EOD skills. So over the past 12 years, Navy EOD has become Special Operations Capable. That is, we're able to operate throughout the battle space, and across the spectrum of conflict with both conventional and Special Forces.

We cast, rappel, fast rope, parachute, and train in small-unit tactics. We have the same mobility skills, and can fully integrate with SEALs and Army Special Forces operators when required.

We've done this because the Special Forces community needs EOD, but not at the expense of having EOD personnel operating with them who are a liability in the field.

Today, Navy EOD forces are the EOD forces of choice for Naval Special Warfare and Army Special Forces. Let me emphasize that SOC is not synonymous with Special Forces. We are not Special Forces. In fact, we have a ways to go in perfecting our suite of Special Operations Capabilities.

Sustainment. Diver effectiveness rapidly degrades if the operation, whatever or wherever it is, cannot be logistically sustained. A good piece of my force structure is dedicated to sustainment, as well as that of EOD Group One.

I apologize if I've told you what you already know. Thanks for bearing with me. For everyone else, my goal was to describe aspects of Navy diving that may not have been obvious, of which you were not aware. I hope it was thought-provoking.

But I've told you less than half the story. I've limited my examples to a few major operations that have been conducted under the sea by EOD Group Two, within the past 2 years. I've left out almost entirely the other EOD group, and most operations conducted ashore.

In conclusion, let me say I wish I had more time. And that if we ever do this again, I think that this subject could merit an entire panel, or perhaps an entire morning or afternoon.

I'd also like to say that it's really an honor to have walked among the living legends of Navy diving. If I can be so bold, I'd like to speak on behalf of all Navy divers today, that we're standing on your shoulders, and they're very broad shoulders indeed. Thank you very much.

**UNDERSEA & HYPERBARIC MEDICAL SOCIETY**

**INTERVIEW OF**  
**GEORGE W. MARTIN**  
**Captain, USNR (Ret.)**

Thursday, February 5, 2004

## PROCEEDINGS

INTERVIEWER: First, let me thank you for inviting me into your home. I look forward to the chat this morning. I wonder if we could start off with you giving us a little bit of your background, like where you came from, where you were born and how you got involved with the Navy.

CAPT MARTIN: I was born in Brooklyn, New York, in April 1933, and my background is Irish Catholic. My great grandfather, Bernard Martin, came here with the potato famine immigrants in the 1850s. I found him and his family on the 1860 Federal Census for New York City.

My grandfather, Joe Martin, was just ten months old at the time. He is on the census. He joined the fire department in 1883 and in 1910, became the Assistant Chief of the Fire Department New York, which he was until 1930, when he was forced to retire at an age pretty close to seventy years old. He was nicknamed "Smokey Joe" in 1912 after he was found in a burning smoke filled basement from which all the other firemen had been evacuated.

As for my parents, on the Smith side, my mother's name was Smith and Carey and they came here from Ireland in the 1880s or early 1890s. We're New Yorkers. I was very fortunate; I was able to go to a great high school, one of the best in the country, called Brooklyn Technical High School. They prepared you for engineering, science and college or the trades. It was a great place to go to high school. There were six thousand boys there.

My father died in December of 1949. I was 16. It was time for me to grow up, and in the spring of 1950 my two best friends, Paul Ryan and Ed Hillis joined the Navy Air Reserve at the Naval Air Station, New York. Because I was under 18, I had to have a parent sign my enlistment paper. When I turned 17, they persuaded my mother to sign one, so the three of us, Paul, Ed and I, were members of the Navy Air Reserve.

The idea was to get a job for the summer. The Navy would send you to a combination of boot camp and airman school. It was eight weeks during the summer, which was great. We reported for boot camp on June 25, 1950, the day the Korean War started. We completed boot camp and airman school and were assigned to reserve squadrons.

My squadron was VF833. The aircraft was the F6F Hellcat. The squadron was ordered to active duty. In fact, most of the squadrons at NAS New York and other air stations were ordered to active duty for the Korean War. I was still in high school, so they left me behind and transferred me to the air wing staff. I was working in the shop of the aerographers, or the weathermen.

I had heard that you could get into the Naval Academy from the Reserve, as well as active duty. I applied and took the exam in April and was among the ones who stood highly enough to get orders to become midshipmen.

I found a summer job. My sister called me at work, which you never did in those days. I mean, work was work. You didn't call home and they didn't call you. She said, "Are you sitting down?" I said, "I'll sit down." She said, "There's a telegram here from the United States Navy, and it says that you are ordered to report Monday, July 23rd, to the United States Naval Academy in Annapolis, Maryland, by 8:00 AM."

I went down, and that started my Naval Academy career. I graduated with the class of 1955. I went into surface warfare, which was where you started if you weren't going into the aviation field.

My first ship was the USS *Hunt*, a tin can out of Newport, Rhode Island. The Navy had more than 200 destroyers in commission in the mid-1950s. I qualified as Officer of the Deck (OOD underway) OOD and after three years, I was ordered to submarine school. I had put in for it. The

nuclear expansion was just happening when I graduated in 1955; the USS *Nautilus* had just been commissioned. The nuclear powered submarine world was beginning to greatly expand.

INTERVIEWER: Before we get into the submarine service, can we back up just a little bit to the Naval Academy?

CAPT MARTIN: Sure.

INTERVIEWER: Can we talk about the life in the Naval Academy in the early 1950s? Perhaps there is some comparison you can make about what life was like then, as compared to now.

CAPT MARTIN: Well, back then in the early 1950s, the Naval Academy and the Military Academy were operated much like monasteries. Your time was completely scheduled, from early morning to late at night and weekends. There was very little time off. There was very little money. We were getting three dollars a month for spending money as plebes.

But it was a great deal, especially for somebody like me. I didn't have a family that was going to turn over a business to me. I certainly had no aspirations to become a lawyer or a doctor or anything like that. I wasn't quite sure what I did want to do. I tested well for English, and they said, "well, George, you ought to be an English major." That was before I got into the Naval Academy. My sister was an English major, so she became a teacher in grade school.

I wanted to be in the outdoors and be active. I wanted to be physically doing something out there. The Navy solved that problem for me. Life at the Naval Academy, of course, is very different now. I am not a midshipman now so it is difficult to compare. The expectations of midshipmen now are very different, 50 years after I was a midshipman.

Of course, they have a lot more money now. The Naval Academy is this enormous institution, with budgets in the hundreds of millions of dollars, I guess. I needed that regimented

life, that scheduled life. It was good for me. You had to participate in sports, which was good for me. I was on the gym team and played battalion intramural sports.

The summer cruises were where I really began to love the Navy. My first cruise was on the heavy cruiser USS *Macon* (CA-132). It was a miniature battleship. The designs were scaled down from the *New Jersey*, *Idaho*, *Iowa* and *Wisconsin* classes of World War II. They had eight-inch guns instead of the 16-inch guns that were on the battleships. But the plan, the layout, was very similar. I just loved being at sea; I loved being part of an organization with a purpose and with a group of men. We had a job to do...beat the communists.

Well, it was in 1951 when I entered; World War II ended in 1945. Five years later I had enlisted in the Air Reserve and the following year I went to the Naval Academy.

The World War II culture was the dominant culture. Many of the professors, the teachers, the naval officers had served in World War II. They knew that the more you sweat in peace, the less you bleed in war. It was a very rigid place. There weren't exceptions made in academics or discipline because you were this or that. But I didn't mind.

INTERVIEWER: Your curriculum was pretty lockstep, too.

CAPT MARTIN: Yes. Everybody had the same curriculum. Your only choice was a foreign language. I had taken French in high school, so I continued with that. You could have French, German, Spanish, Portuguese, German or Russian. I continued with French and enjoyed that.

I think I was in the last class to have the course in naval boilers. When I became Chief Engineer on the Destroyer USS *Hunt*, I was so fortunate to have had that course in naval boilers and all the auxiliary machinery, the pumps, the de-aerators, and the steam plant. That course provided me with knowledge that gave me credibility when working with the enlisted men whose job it was to operate and repair that machinery. Anyway, I felt very fortunate to have had that

course. Of course, the Navy was using steam power back then. Then, in the 1960s, they moved toward diesel power for the smaller ships. Then, they moved into gas turbines. Of course, nuclear power for surface ships as well as submarines came into place.

The degree that a midshipman graduated with was a Bachelor of Science degree, and that's all it says. It doesn't say anything about engineering or what science. You had a lot of physical science; chemistry and physics; electrical, mechanical and navel engineering. The courses that were hands-on: wiring motors in the juice labs, for example. If it was hands-on, I could do it. I was not a great student in terms of reading books and that kind of thing. It was just a great place to be.

INTERVIEWER: How many students were there?

CAPT MARTIN: My class, I think, entered with about 1200 and graduated about 760 or so.

INTERVIEWER: That was a very large attrition compared to today.

CAPT MARTIN: There were just great things. It was a real opportunity for somebody like me, who wouldn't have had that opportunity had I gone to City College in New York. I was very fortunate. I knew it at the time. One of the nice things was that they'd send part of the brigade off to a football game in the fall, an away game.

During my first class year, they sent my battalion and another battalion to Philadelphia for the Penn-Navy game. A midshipman in the class ahead of me had gone up there the previous year. He said, "Martin, you go to that nurse's dance at the University of Pennsylvania. They'll have a little tea and dance. You sign up for that." I signed up for that, went to the dance, saw this very attractive young woman across the crowded room and asked her to dance. I invited her for the Army-Navy game, and went to visit her at Christmas. She was working as a nursing student at the University of Pennsylvania. I was hooked, hook, line and sinker. It all happened so fast. You couldn't get married anyway until you graduated, but anyway, we did get engaged. She came to our

graduation. She is up there in the class graduation picture on the right-hand side. My mother and sister are sitting next to her. We've been married 47 years and thank God for that.

INTERVIEWER: Your marriage was during commissioning week?

CAPT MARTIN: Actually, no. It was a year later. She didn't graduate until June of 1956. As a nursing student, she wasn't allowed to get married either, so that was a good idea.

INTERVIEWER: It was love at first sight.

CAPT MARTIN: It was pretty close to that. We know three midshipmen who live in the neighborhood here. There is a set of twins. I actually helped get the second twin into the Academy. They came by at Christmastime, nervous and everything. But they're doing fine. They're both very bright young men. They had superior academic preparation and ten years of competitive swimming under their belts. I met one twin at the neighborhood pool here, the Flower Valley pool. I went over and asked him what school he attended. He said he went to Georgetown Preparatory School. "What are you thinking about for college?" I asked. He looked like a guy you would want at the Naval Academy. He said, "Well actually, I've applied to the Naval Academy." That was the right answer. We talked, and he was concerned because he had really, really poor eyesight. I couldn't believe it. As we were leaving, he said, "I have a twin brother who would like to go there, too." I said, "Well, have him give me a call." A week or so later at the pool, I saw this other young man who was also the kind of guy you want at the Naval Academy. I went up to talk to him and he told me he had just finished his plebe year at the Naval Academy.

INTERVIEWER: You've got a way of spotting these folks.

CAPT MARTIN: I was the Blue and Gold officer for Maryland for ten years, from about 1972 to 1982. Yes, that was a good experience. That was a volunteer position in association with the Naval Academy. I am very proud of it. In fact, I have a book here signed by Arleigh Burke that my

mother gave me. He was Chief of Naval Operations from 1956-1960. I was up there for an award for the Naval Academy Information Program work. Arleigh was, of course, retired by then, but I knew him through a work context. Anyway, he signed my book. I'm just proud to have that.

INTERVIEWER: I served on the admissions board for four years when Jack Renard was there.

CAPT MARTIN: I finished like in 1982 or 1983. He started that next year.

INTERVIEWER: The inputs of a Blue and Gold officer were always very valued in the deliberations.

CAPT MARTIN: Sure.

INTERVIEWER: You left the Naval Academy and went to surface warfare.

CAPT MARTIN: That's right. I was on the USS *Hunt* (DD 674), a tin can, as they say, out of Newport. They really were tin cans. A .50 caliber bullet could go through any part of the hull, and even the gun mounts. But it was a wonderful experience.

It wasn't easy for me. I liked being at sea. I liked being underway. I liked going home, too, but I just loved being at sea. It was where I wanted to be. My first skipper was then-Commander Gene Farrell. He went on to become Rear Admiral. He visited and stayed with us a couple of days last spring and is coming back this year, in April. He and his wife will visit for a couple of days. He did a lot for me. It was the first example of a win-win that I had ever encountered in my life. I had orders to the USS *Ranger*, a pre-commissioning unit, being built in the Philadelphia shipyard.

I had wanted to go to submarine school because both of my roommates at the Naval Academy had already gone into submarines and were sending letters and saying, "George, you ought to get in," and that kind of thing. He called me into his cabin one day, and I was terrified of this man. Commanding Officers were really very imposing figures. This man still is. He said, "Martin, have a seat. I have an advance copy here of your orders to the USS *Ranger*, pre-

commissioning. You could get lost on a big ship like that, with 200 officers," which was true. I didn't know that, but he did. He said, "I've got a alternate plan here for you to consider. How about if I send you to Destroyers Atlantic (DESLANT) engineering school. When you come back, you can relieve Pete Watson, my chief engineer, and you'll be Chief Engineer of the *Hunt*."

I said, "Well, sir, I was hoping to go to submarine school." He said, "I can certainly put in a favorable endorsement for that." I said, "Yes, sir." DESLANT Engineering school was ten weeks long.

It was hands-on and class work, too. It was hands-on and classroom engineering. Captain Farrell had the orders changed to stay on the *Hunt* and in the meantime, he was relieved. The new skipper came on and sent me to the school and I put in for submarine school, which was favorably endorsed.

I relieved Pete Watson as the Chief Engineer of the *Hunt*, and it was just great. Gene Farrell, Pete Watson, Ed Flowers and I are still in touch and visit...even after fifty years. I loved it. These were the 2100 ton Farragut class. They could go 39 knots. The *Hunt* went in for a shipyard period, which was a lot of work. But I loved it in the shipyard. We were in the Boston Navy Yard for three months.

The Chief Engineer was really the go-to guy for everything there is to do in the shipyard. I just loved the organization of the yard. I loved the workers. You don't always get what you want, but it was just a great experience in management, in learning how people, who were not members of the crew, work. It was just great.

We came out of the shipyard and went through refresher training. Then, we came back. It was the end of June by then. Subsequently, we got the Division E, which was a big thrill because

the *Hunt* had not been a great ship when I first got on board. But Gene Farrell had shaped things up and the new skipper came on. He was an experienced skipper, Sam Collins.

He just took it and rode it. That was my surface warfare world. I went to submarine school just down the road a bit from Newport, to New London. I was married. We had our first child, Barbara, who was about a year old. We moved into the married officer quarters, which was just a wonderful place for a young Lieutenant Junior Grade. It was very nice compared to apartments and things like that you could sublet in Newport at the time.

INTERVIEWER: Did you have to select whether you wanted to go to nuclear or diesel at that time?

CAPT MARTIN: No. That decision was always in the hands of Admiral Rickover. It was based on your class, and we didn't have that many nuclear submarines and we had over 100 diesel-electric subs. Submarine school then was strictly for diesel-electric. It was only after you had a year or so in diesel-electric subs and earned your dolphins, as a qualified submarine officer that you were nominated for nuclear and went back for your interview. Based on that, you were selected for nuclear power.

Submarine school was six months. It was mostly classroom work, but you got out on the submarine for a couple of days every other month. But submarine school was great; there was a lot of camaraderie. It was fairly intensive.

Upon graduation from submarine school you could select your submarine and home port. A classmate of mine, Bill Walden, said, "George, you've got to go to San Diego. It's the greatest place in the world." Of course, I grew up in Brooklyn, New York. My wife is from Bethlehem, Pennsylvania. We're east coast people, but after a while, I saw advantages in being 3,000 miles

away from her family and my family. So I took a submarine out of San Diego, the USS *Catfish* (SS-339).

There we were. We drove across country, and I reported to the *Catfish*. Of course, it was a lot smaller, nine officers or so. There was a crew of about eighty to ninety. I had my first Western Pacific (WestPac) cruise, which was scheduled for six months but ended up being seven months long. But that was kind of standard, actually, in those days. Some crisis would develop and we went for some other patrols. But it was good, good duty. I qualified in submarines.

INTERVIEWER: At that time, it was a diesel-electric. You were primarily on the surface the majority of the time.

CAPT MARTIN: That's absolutely true. You dove for exercises, which could last for days. You might have to come up to snorkel, recharge batteries and things like that. Going from point A to point B, though, was done on the surface, unless directed otherwise. When leaving from San Diego, going to WestPac, you went through Pearl Harbor and checked in with Commander, Submarine Force Pacific (COMSUBPAC). The captain got his orders from the admiral, and the staff would give him the word on what your projected deployment was going to be like.

The next stop for us was in Yokosuka, Japan. It was a very large U.S. Navy base and repair facility. It had been a major Japanese navy base and repair facility, so it had dry docks. They had machine shops and electrical shops and everything like that. The submarine probably took six weeks to get over there from San Diego to Pearl Harbor and staying a few days, and then we'd go on up to Japan. There were always things to repair on a submarine or a ship.

At the Yokosuka navy base, the Japanese workers swarm aboard. I was the communications officer, the electronics countermeasures (ECM), the crypt- security and everything like that. We had trouble with our ECM mast. This Japanese man came aboard wearing his hard hat and shipyard

work clothing. He had a blueprint for our ECM mast, which, back in San Diego, the submarine tender didn't have, and the submarine certainly didn't have. It might have had "confidential" on it or something like that. But, as I said, I understood shipyards. I loved them. Of course I didn't speak any Japanese beyond the daijobi (means OK) stage, and he didn't speak any English beyond 'yes' or 'no.'

Fortunately, with blueprints, you can point out things. He'd done this twenty times or more before. He knew what the problem was, and he knew how to fix it. Here is another story: We went through a couple of other ports and things and came back to Yokosuka. We had a noise in one of the propeller shafts. The diesel-electric class I was on was a Guppy II, a converted World War II submarine, had two shafts and two propellers. There was a little noise in one of the shafts. Such a noise could give away your presence to an enemy and you could be sunk..

During a cavitation exercise, we went down to a given depth and increased the revolutions per minute (RPM) until we reached the cavitation point. Then, we stopped, went a little deeper, increased RPM and charted the cavitation point. It was for silencing. Of course, cavitation is a dead giveaway for opposing forces.

The captain went up to the Commodore and said, "We have this shaft problem." We were supposed to go out on a special patrol. There was a time factor. Boy, did he get action. They sent us to sea with an old-time Japanese engineering officer. This man was superb. We went out, ran our cavitation point, and he could tell which bearing it was that created the noise. We went to sea. There was this little man. He was about five feet tall and probably eighty years old. He sat in the corner of the wardroom trying to be inconspicuous. The captain was very gracious to him. Everybody was. Well, anyway, we went out and were in the cavitation trial. The Japanese engineering officer said that it was the number two bearing on the port strut. We came back in and

didn't even tie up. They sent us directly into the dry dock. They had to go through the whole dry dock procedure. Anyway, they replaced that bearing, the number two bearing on the port strut. It was at about the time that the captain went up to make his report when they told him that the Japanese engineering officer was a retired Rear Admiral of the Japanese Navy.

Of course, Japan was a different country in 1959. It was an occupied country in a lot of ways. We weren't allowed to use American dollars. We exchanged dollars for scrip, which was a U.S. printed currency. They didn't want dollars floating around in the black market and things like that. There were very few automobiles. The people were still very short. Everybody was pretty respectful on the street and things like that. Of course, sailors didn't get to go very far beyond the ship.

INTERVIEWER: You didn't detect any animosity from the Japanese toward the Americans?

CAPT MARTIN: No. What would they say? They don't go around expressing emotions anyway. Whatever they thought, they thought, but they certainly didn't tell you about it. We went out and made our special patrol. I always have some interesting stories about that. Of course, it was very cold. We had some surface transits to make that were very, very difficult because the whole point of a surveillance mission is to remain undetected..

We went through something like a miniature typhoon or hurricane in one transit. We were on the surface, at night, with no running lights. We were rolling about 45 degrees to each side. Of course if you were on the bridge it was pretty wet. The lookouts, the port and starboard lookouts, they were just kids.

We were rolling over on one side. There was this fellow. His name was Ford, and he was from Oklahoma, a little, short redheaded guy. He said, "Mr. Martin, don't leave me!" He was dead serious. We were that far over but were strapped in. We had safety precautions and equipment. It

was a good thing that we were strapped in because when the water came up underneath us; it floated us. It had that force, that buoyant force that pushed you upward. If you were just standing there on your feet, you'd be floated off your feet and tumble over the side with the waves. Anyway, I said, "Ford I have no intention of going anywhere."

The other story took place when we were on our patrol station. A storm came up and we were at periscope depth. We were having difficulty maintaining our periscope depth and was concerned that we would broach. In other words, we would be forced up to the surface when it was daylight, and we were required to remain undetected. The captain ordered a deeper depth, so we could use just the attack scope, which was the little 1.4-inch diameter scope, but we still couldn't hold our depth.

He ordered eighty feet, which is below periscope depth. Of course, not using your periscope, you would want to be close to the surface in case you heard anything you wanted to look at. Well, the storm was increasing. Eighty feet wouldn't hold it. Next, we went to one hundred feet. We were rolling around at a hundred feet, and were still concerned about broaching. We went to 120 feet, and I had the dive. We were at 120 feet. You tried to conserve battery power by going at minimum speed to maintain depth. If you increased speed, you could maintain your depth.

With diesel-electric submarines, you had to snorkel and charge those batteries every night. Anyway, we were 120 feet with minimum speed, maybe two or three knots, to try to maintain our depth. A wave came over us. The trough came down and we were on the surface in about ten seconds.

INTERVIEWER: Wow.

CAPT MARTIN: From 120 feet, we were up there on the surface. Well, we were exposed. The captain came running in. He said, "What's the problem? Get it down. Open the vents. Flood

Negative” He put the scope up and looked around. He let me look around, too. Neither he nor I had ever seen seas like that before or since. From 120 feet, the trough of that wave got close enough to pick us right up.

INTERVIEWER: What would you estimate the wave height was?

CAPT MARTIN: Well, it had to be over fifty feet.

INTERVIEWER: Wow.

CAPT MARTIN: Anyway, it all counts on twenty, as they say. We completed our patrol. That was the pinnacle of your deployment. Then, we were scheduled to go home to San Diego. They had another special deployment for us to go on. That was down at the Equator. I was able to see the Southern Cross and Polaris was just above the horizon. I loved all of that.

INTERVIEWER: What was the primary mission of submarines at that time?

CAPT MARTIN: It was surveillance.

INTERVIEWER: Was it surveillance of the Russians?

CAPT MARTIN: Yes. It was surveillance and attack. About that time (late 1950's) the primary mission became anti-submarine warfare (ASW). The Soviets were the big threat, and they were building submarines more quickly than we were. But we had this World War II surplus that had been put out of commission and into mothballs and so forth. Then, we put some of the subs back in for the Korean War. By 1952, we realized that the Korean War was another buildup to further communist expansion in Asia.

I was over there on the *Hunt* when Hungary was forcibly reoccupied by the Soviets. You lived with the Soviet menace every day. I'm not saying that the average American did. But kids went to school and had dive under the desk drills for protection from nuclear bombs.

INTERVIEWER: I remember doing that when I was in elementary school.

CAPT MARTIN: Sure. Anyway, diesel-electric Guppy II was a first-line fighter submarine at the time. We did our job. We had a hundred diesel submarines about that time. They were all working around the clock. The feeling of the constant pressure of Soviet expansion in Europe and Communist China in Asia was very real if you were right there on the front lines.

We were on the front lines. It was very real. But it was a tremendous motivator. You are making sacrifices, as far as being with your family and things like that, but you were doing it to protect the United States. We all understood that.

The missions, then, were primarily surveillance and ASW. But ASW really came in more into the 1960s; that was when the Soviet submarine expansion really took off, whereas in the 1950s, it was their surface fleet that was considerable. Of course, you didn't know anything. We didn't have satellites. The only things you learned came from when you got some information from some aircraft, that was running up and down at the 12-mile limit, listening and learning what it could. It would take that back and filter it, and the information would be added to other intelligence and they would try to put together a picture.

One interesting story happened when it was night and we were on station. We put the scope up for a look, as we so often did. We had the scope up one night and saw this light going on and off, a navigation light. It would go on for a couple of seconds and go off, repeating the pattern. Of course it wasn't on our charts but we knew the Soviet charts available to us were wrong on purpose.

Anyway, that was one important piece of information from our report.. Of course, it told us that somebody had to be transiting in or out of there because they turned on the light. None of their navigational aids were on except when they wanted them on for their ships to go through. That was the story of submarines from San Diego.

INTERVIEWER: Then, you went back to San Diego. Was that when you got into the submersible business?

CAPT MARTIN: I qualified in submarines, I was a chief engineer, and I served three years on the *Catfish*. We were getting ready to work up to go to WestPac for another deployment, and a message came out that Lieutenants Walsh and Shumaker, from the bathyscaphe *Trieste*, were going to be transferred, and if you qualified in certain ways, you could volunteer.

INTERVIEWER: Had they already made the deep dives?

CAPT MARTIN: Yes. That was January of 1960 for the deep dive. They were tied up there in San Diego, in the water, and they went out to sea right there. Of course, it was sitting very low in the water.

I said to myself that I was coming up for rotation. I had three years on the *Catfish*. I might go to postgraduate school or something. But as a lieutenant, I wasn't going to do anything too exciting. I think that by that time, it was pretty clear that I was not going to go to nuclear power school. They needed bright people and that wasn't where I was. I put in for the *Trieste*. I also went over and met Walsh and Shumaker. They were from the class of 1954. I met Andy Rechnitzer, Dr. Andreas Rechnitzer, who was the chief scientist. Larry Shumaker took me to the bathyscaphe. You enter through a narrow access trunk with a little ladder. I think it was about 20 inches in diameter. Larry was something like six foot four. It was a real job for him to get down there. Anyway, we got down into the sphere in San Diego Harbor. You could look out the window but not see anything because the water was so turbid. He said, "I'll be right back." He shut the entrance hatch, which weighs 378 pounds, and went on up topside. I started looking around inside the sphere. My escape had been cut off and I began to feel uncomfortable. Then I said to myself, "I am 15 feet below the

surface, in a watertight steel sphere that has been down to 18,000 feet and returned safely.” I calmed down and looked at the rudimentary instrumentation

This was the Wright Brothers' stage of deep submergence. Not that I was any Wright brother, but we were at that stage at which almost anything we did was an improvement, an upgrade. Well, anyway, I had this really funny feeling. I thought, "Gee, I'm in here all alone. The hatch is shut. I guess they'll come back and get me at some point."

INTERVIEWER: Was this a test?

CAPT MARTIN: It was a test.

INTERVIEWER: Oh.

CAPT MARTIN: Shumaker came back some time later, but not as soon as I thought he would come back. He must have been gone 15 or 20 minutes. If you were down there, of course, it was a long time. He may have just gone up and taken a phone call or something like that. It was a very busy place.

Anyway, I was selected and ordered to go. I was detached from the *Catfish* to report to the Navy Electronics Laboratory in San Diego, in March. At that time, you had like a six or seven-day window to report. Anyway, I got back on the *Catfish* and went over to WesPac. We did pretty much what we did before. We were in Sashibo (?), Japan, which is on the southwest side of the Japanese islands. I was detached, took a Japanese train up to Tokyo, and then a propeller-driven aircraft full of women, children and crying babies. It was a contract flight.

In other words, the Navy contracted with other airlines to run these flights. They had people going back and forth every day. The passengers were dependents, sailors, and other officers of the military. Anyway, we flew from Tokyo to Hawaii, and had a two or three hour layover there for refueling purposes.

Then, we went on to San Francisco. Then I got a flight on PSA (Poor Sailors Airline) to San Diego and got home. I reported to the bathyscaphe, and Don Keach had reported just a week or so before I got there. He was to be the officer in charge. There were just the two of us assigned. He was to be the officer in charge and I'd be the assistant officer in charge. The laboratory was a fascinating place to be after six years on ships and submarines..

INTERVIEWER: Those were submersible pilots three and four?

CAPT MARTIN: Correct. Walsh was one, Schumaker was two, Keach was three...Keach died in 1999...and I was became operator number four.

INTERVIEWER: The *Trieste* was such a specialty service. Did you consider that it would be an enhancement or detriment to your career?

CAPT MARTIN: I knew it was not a mainstream thing. When you were a lieutenant, you did not know a whole lot, but I knew it was not mainstream. Mainstream was nuclear power. I was not going to be in nuclear power, so why not do this? It was sea duty. But at that time, of course, I had six years of sea duty, rather arduous sea duty. This was a shore duty for rotation and sea duty for promotion. You got submarine pay, which was unheard of in those days.

Once you left the submarine and were detached, that day, your submarine pay was cut off. I had a lot of benefits there in San Diego. My wife loved San Diego. Of course, being on a ship, you're certainly not there as much. I didn't get to enjoy a lot of it. But it still was a very nice place to be. Of course we had friends there.

I knew it was not mainstream, but for me, it was just right. Walsh and Schumaker had made the deep dive in January of 1960. Over the next two years, they had spent money on some refurbishment of the bathyscaphe and some upgrades. They hadn't really gotten it back to sea. It

was an experimental craft. Everything was one-of-a-kind...experimental. Everything took time to order, receive, install, and test.

Keach and I relieved Don and Larry. Keach told me our job was to get the bathyscaphe to sea with scientists on board. The public relations phase was over. Everybody knew who and where we were, and our job was to get scientists to sea doing ASW research because 6.1 research funds were paying the bill.

The bathyscaphe had a fair amount of financial support, compared to the submarine. The submarine had reasonable support. But on the destroyer, it was always hand-to-mouth. You would ask, "Do I want to buy this part I need for the pump, or should I buy the line I need to tie up to go alongside." There was always a day-to-day spending question. It was a great job. It was a Mecca for people who were excited about a new venture. Hey, we were going under the sea, and it was not a warship. We were going to find out what there was to find out underwater.

There were more questions than there were answers. But that attracts a certain type of individual such as Alan Vine...Al Vine of *ALVIN* fame, from Woods Hole Oceanographic Institution. He came about every six weeks to see what we were doing and to probe here and there to insert his thinking into our work. He also collected ideas to take back to Woods Hole for design of *ALVIN*. It was an experience.

Industry was interested. How did we build a deep submersible, or a piece of it? It was clear that the bathyscaphe *Trieste* would not be duplicated. Nobody wanted another bathyscaphe. They were too clunky. They couldn't do what scientists and operators wanted. Maneuverability was something they didn't have, for example.

Everybody in American aviation and space industry wanted to get into this new deep submergence arena. They had a lot of engineers, a lot of talented guys trying to figure out how to

do it better. There was competition. It was wide open because nobody knew what the Navy was going to do next. Were there opportunities in commercial work for submersibles?

INTERVIEWER: Everybody was anticipating a wet NASA?

CAPT MARTIN: Exactly. Those were the expectations. I reported aboard in March of 1962.

*Sputnik* was launched in 1957. By 1962, I guess, John Glenn had spun around the earth. But even the idea of a wet NASA was actually just four years later, in the mid-1960s. The aerospace industry was anxious to see what could be done, essentially starting with a clean sheet of paper. What are the requirements, that sort of thing

The staffing assigned to the *Trieste* included Keach and I, and there were eight enlisted men assigned to us from the Navy Electronics Laboratory. There was Giuseppe Budno, who was the key man, really, because he had worked with the Piccards at the Castelleurare shipyard in Italy when the bathyscaphe was built.

Piccard had brought him along, Jacques Piccard, who sold the bathyscaphe *Trieste* to the United States Navy. Piccard had brought Giuseppe along with him. Then, when Piccard sold the *Trieste* to the Navy, Giuseppe was offered a job to become a civil servant and continue to do the work on the *Trieste*. What he did was maintain the float and sphere systems for ballasting and de-ballasting the air, gasoline, and steel shot. He was in charge of opening the vents so that we could submerge. He was in charge of closing the vents, and when we surfaced, getting the water and air out. All of the mechanical operations that had to do with operating the bathyscaphe at sea were his responsibility.

He did it extremely well and was very conscientious. He was what you would call 'old school.' That is the right way to do it. You didn't do it any other way because that was is faster or somebody thought it was better. No, that was the right way to do it based on experience. There

were fairly delicate things. For example, there was disposable ballast. We had two tubs that held about eight tons each of this disposable ballast. The problem was that the American shot had different magnetic properties than the Italian shot. This was the same shot that is used to sandblast the side of a ship's hull or any surface on which you wanted to take off a lot of surface material. The electromagnets controlled the orifice that discharged the shot which was discharged by gravity, but you had to open the orifice. It was an electromagnet that we controlled from the control panel inside the sphere.

We had a certain amount of the Italian-made shot that they brought with the *Trieste* when they made the deep dive. We ran out of that, so they brought American steel shot for us to use. Well, American steel shot would become permanently magnetized in the orifice and what you needed was shot with the magnetic properties suitable for the design of the orifice and magnet. The U.S. shot didn't work to Giuseppe's satisfaction, in terms of how fast it would stop after you magnetized the orifice. If you had to let go of shot, there were lots of cases in which you had to do that, you didn't want some magnetized shot hang-up so electro-magnetized that it was frozen. That was a very crucial thing.

Giuseppe took care of things like that. But then he had to go order this shot from Italy. Fortunately, in those days, you could do stuff like that.

INTERVIEWER: What was the sale price for the *Trieste*?

CAPT MARTIN: the Office of Naval Research (ONR) paid about \$350,000 for it. It was the best buy; it was a steal. Nobody in America had ever thought of building something like it, you know. We built ships, aircraft carriers, merchant ships and submarines. But what did we want this for? August Piccard, the father of Jacques, was a true genius. His son, Jacques, was extremely

dedicated, and very well trained in engineering. They were brilliant men. The United States was very fortunate to have the opportunity to buy this thing they invented.

INTERVIEWER: Your orders were to take the *Trieste* out into open water and get it working?

CAPT MARTIN: Yes. The scientists were from ONR or universities. They could be either, but because we were at Navy Electronics Lab, the scientists were already there and they had gotten the first call on it. The Scripps Institution of Oceanography was just seven miles up the street, in La Jolla. We were in San Diego Harbor. There were NEL scientists, too. Dr. Eugene La Fond had this Sea Floor Studies Group.

Dr. Ed Hamilton was one of the geologists. In one of his experiments, they were basically trying to figure out what would affect bottom bounce sonar. They came up with the idea of bouncing the sonar signal from the surface warship or later, a submarine, down to the surface of the sea floor. Then, where would it go? What was the predictability of its reflection and refraction, and how could we use that information to recover the signal? Would the return signal come back the same way? Would it go through the water instead? There were a lot of questions were being asked.

Until that time, nobody had worried about it. There was a new problem. The bathyscaphe would take you down and you could stick your instruments into the sediment and bounce signals off and measure it. It was a wonderland for the curious person. The scientists were just beautiful. They were all well trained. They were focused.

Dr. Eric Barham was a marine biologist, and he was working at the lab at the time. As a marine biologist, he was concerned with discovering what all of the marine biota were and how fish showed up on sonar. There was a phenomenon called a deep scattering layer that confused a sonar signal. In other words, there was something in the water that seriously attenuated the sonar signal.

It didn't go through; it got scattered. Then you had a lot less sonar information continuing past that field of biota and you got a lot less signal back.

There were scientists pulling net hauls, trying to pull in nets. There was some kind of marine organism in the net, but what was it? What did it look like? Could we shoo it away and make it go away or something? That was the next part.

Barham went down in the bathyscaphe with instruments and net hauls to capture samples of biota. He actually figured out that the deep scattering was caused by a certain kind of marine organisms. They are called Siphonophora. A Siphonophora is like a long, twenty to thirty to forty-foot long chain that you could see through. In other words, it was almost transparent. It was like a big jellyfish, but stretched out twenty-feet. It was so delicate that when you put a cast down and pulled it back out, you never found any Siphonophora in there. They had been broken apart on the way up. They figured out that these Siphonophora was the deep scattering layer. Then, you could find out what feeds on them and what size they were that confused the sonar.

INTERVIEWER: There were a lot of different questions that you were asking or answering. There wasn't really any typical operation. Can you describe what a typical day would be like, going out, and what the operation was like?

CAPT MARTIN: There was a lot of preparation work. Each scientist had his own instrument package. He had to build it himself, or get the laboratory to build it for him, and that was what they were there for. He had to promote his idea with the superiors in the laboratory and his scientific peers, that their experiment was the smart thing to do.

He would get his instrument ready. It usually involved some kind of electrical/electronic signal information. He had sensors, and they would go outboard. We would carry the sensor

outboard with us. Then, he had control through electrical wires, which came through certain electrical penetrators and went through the hull into the sphere.

This was the tough part of the job. How did you safely get electrical signals from outside, through a steel hull? The wire was inside, but if something broke, you didn't want the water pressure of several thousand tons per square inch pushing that wire through the penetrator, into the sphere and through your head.

Electrical penetrators were very difficult jobs. Of course, this was back in the beginning. The Picards had one that worked down near 35,800 feet, but it didn't work for long. You were always repairing or trying a new design and things like that. The enlisted men were mostly in the electronic field, with some mechanical background. Giuseppe did mechanical work, and the crew did electrical/electronic work, and then, you had to coordinate with the scientists. We were getting underway. We wanted you to have your equipment on a couple of days beforehand, to test it out, to see if it worked with our battery power supply package, and our penetrators.

Then, we were towed to sea. We were not self-propelled, so we had to be towed out to wherever we were going. The day of the trip would arrive and it could be foggy. Well, it is one thing for a ship to go out in the fog if it has to. But it was another thing to take out an ocean-going fleet tug or salvage ship to tow the *Trieste*. The towline would be a mile long! You had little control over where that tow was going. There could be a lot of traffic, Navy traffic or fishing boats, coming in or out of San Diego Harbor. Therefore, on some days, the dives would be cancelled. We only had the Navy ships for one day each because they were very tightly scheduled. Everybody wanted those tugs, for towing sleds for gunfire practice and whatnot.

INTERVIEWER: You didn't have a dedicated support ship?

CAPT MARTIN: No. We were allotted three or four days of tug service every quarter. It was a quarterly conference. You did the best you could. If it was the day to go out, you went out unless the scientist said, "Look, it's not working. My equipment doesn't work. We'd be sitting out there." That happened sometimes. We'd just pass it up. Sometimes, we weren't ready. Usually, we were.

We got towed to sea. Fortunately, in San Diego, on the western side of the continent, they're called 'continental borderlands,' but you don't have a shelf like you do on the east coast. Four miles off the Buoy One off San Diego, you could dive in 2,000 feet of water. At maybe ten miles out, you could dive in 4,000 feet of water. But you had to go out much further [on the east coast] to get deeper than 4,000 feet.

There were all sorts of stuff. You had to get the tug, you had to get the scientist. You had to get the bathyscaphe ready and then, the weather had to break for you. We got scientists out there. Once they went to sea, they were sold. They'd never seen anything like it. They'd never been able to look at the water column. What is it? What are those things out there? To go down and look at the sea floor was amazing for them. Now, scientists have been pulling up buckets of mud and dredging and things like that for hundreds of years or longer. But to go down and see the physical features of the floor was great. We went down and took core samples, and the core samples were right there in front of you. Well, you could move the *Trieste* around to where the scientists wanted a core sample to be taken. They could make very precise measurements of the core. If you dropped it from an oceanographic ship on the surface, and it goes down to 2,000 or 4,000 feet and gets hauled up, you can lose a lot of information about the core.

INTERVIEWER: You must have felt analogous to those people who walked on the moon. There were very few people who had actually been to the bottom.

CAPT MARTIN: Very few.

INTERVIEWER: You were certainly blazing new territory.

CAPT MARTIN: It was very exciting. The people were so professional. I had never met Ph.D.s before. Where would I have come across those people? As I said, I knew it was not mainstream. But it sure was exciting enough for me. That was great.

INTERVIEWER: How safe did you feel inside the sphere?

CAPT MARTIN: Surely, surely. We'd get enough scientists out there, and they were starting to get papers published. The Bureau of Ships said, "We're concerned with the physical welfare of you inside that steel sphere at 4,000 feet. Our engineers have never been able to look at it and analyze its structural capabilities. Is it strong enough? How strong is it?" Well, we knew it had been down to 18,000 feet. It was called the 'Terni Sphere.' Terni is a place in Italy where it was made. It was safe. But the Bureau of Ships was responsible for these things.

INTERVIEWER: This was a different sphere from the deep dive.

CAPT MARTIN: Correct. The deep dive used the Krups sphere made by Krup of Germany, to go safely to 35,000 feet. It was almost six inches thick, actually, whereas the sphere was like three and three-quarters to four inches thick. BUSHIPS sent Pete Palermo from the David Taylor Model Basin, Carderock Division, Navy Lab, and he instrumented the sphere with strain gauges. We went out to dive, and he had an instrument that took the strain gauge readings and brought them back. That gave him real data to analyze.

That winter (1962-63), we had taken the sphere apart at the Naval Repair Facility in San Diego to see actually how it was manufactured and how the two hemispheres were constrained. We did that and put it back together. The flange at the mid-section had been clamped together by rivets. There was a gasket in there, and we put it back together. It took a while. There were other things in process. We were trying to develop new electric motors. We were trying to get better

batteries. We were using Sears' best automobile batteries as our propulsion source and for the external lights. Each light was 1000 watts. In the dark water, 1000 watts doesn't give you very much. You need 4000 to 8000 watts of power. You need electric power, and we didn't have very much. Anyway, we got the sphere back together. It was about March 26, 1963. We filled the float full of gas and were getting ready to make our first post-availability dive, in April. Things were going along pretty well. We hadn't made the dive yet. *Trieste* was sitting in the water at the waterfront. The electrical/electronic equipment, the ballast control systems and depth sounders and the other equipment was in place. Everybody was doing good work to make our schedule to be ready for sea by mid-April.

Then April 10 came. It was a Thursday. I usually left work about six in the evening. That afternoon, the guard at the gate, instead of just waving me on, stopped, came over and said, "Lieutenant, did you hear about the submarine?" He said, "There's a submarine down in the Atlantic." I was a little skeptical, frankly. Submarines surface all the time and the antennas are grounded out.

But I got home and walked in the door. Dorothy was standing there in tears. She said, "*Life* magazine has called. *Time* magazine has called. They told me a submarine is sunk and they want you to give them the story. What's happening?" she asked. I didn't know anything.

INTERVIEWER: Now, *Life* was calling because they knew of your position as the *Trieste's* operator.

CAPT MARTIN: That's right.

INTERVIEWER: They assumed that you would know something?

CAPT MARTIN: They assumed that I would know what is going on. They had inducements, like, "Give us your exclusive story and we'll send you to Bermuda." Of course, we were living in San

Diego. The Navy had sent us to the best home port. Nothing was going to be an improvement. But that was the way the media worked. Of course, with the deep dive, there had been a lot of press activity.

Keach called and said, "You heard the news. Be at the compound at seven-thirty." I went back down at 7:30. Keach and I and the chief scientist, a fellow named Ken McKenzie, were there. His boss, Dr. Curl, who was the head of the sea floor research studies and everything like that was also there. He was a marvelous man and a dedicated scientist. The Executive Officer of the Navy Electronics Lab was there. His name was Captain Peterson. The Commanding Officer, Captain Mason, was in Washington at the time, at the Bureau of Ships. We were a Bureau of Ships activity. The only information that we had was that the name of the ship was the USS *Thresher*, SSN-593.

The last known location was approximately 270 miles east of Boston, Massachusetts. Ed Hamilton had brought the chart over and said, "This is where it is. It's on this continental slope, a six to ten-degree down slope. It's rugged. It's not anything flat, like we have on the continental shelf or with the deep sea." But that was all we knew.

Of course, Captain Mason was in Washington. He'd been up to answer lots of questions. He called Captain Peterson and said, "Tell them to get ready in case they're called." The next day, we were called. It was Good Friday. We then had to take the gasoline out of the float, which was a big job. There were thirty-five thousand gallons of aviation gasoline. We had to tell the crew to pack up. We knew we were going. We did not know how long we were going to be there. But it was going to be a long time, we said. We didn't know. It wasn't a week or two or anything like that. We packed up everything that we could. Of course, they had a wonderful civilian staff there at the Navy Electronics Lab, and those guys packed up everything.

We packed up lock, stock and barrel, and the crew and I and went on the USS *Point Defiance*, LSD, and through Panama Canal. We arrived in Boston on April 28. They took us into a dry dock so that we could get things checked out, and that took a few days. Then, they lifted us up, put us in the water and we filled the float with gasoline. All the steel shot was replenished and we made ready to go to sea. Nothing happened. You know, everything had been rush, rush, rush. The Navy's search was still in the papers. It was disturbing, too. Not only the Navy because of the bad press, but the families were there, of course. Most of these sailors were from New England. One hundred and twenty-nine sailors were lost on the *Thresher*, and the ship had been built in the Portsmouth Shipyard, the Navy's oldest shipyard. They had a lot of tradition there. It was a mighty blow to the national psyche. Plus the term 'atom-powered submarine,' which was part of the headline in the *New York Times*, was unnerving. The public's connotation of atom involved atomic bombs. The idea of a submarine running on atomic power was a new thought, and not entirely a welcome thought because of what might happen if one blew up.

INTERVIEWER: What were the surface assets that the Navy had to send down?

CAPT MARTIN: The immediate effort was sending aircraft over the scene looking for debris. They sent submarines into the area to see if they picked up any sounds of anything. That was within the first 24 or 48 hours. Of course, a surface ship picked up a plastic booty that sailors wore over their shoes when they went into the reactor compartment. There was an oil slick, too, but nothing that said, "USS *Thresher*." There was some skepticism in the press. "What is this about you not being able to find this submarine," they asked. That was carried out in the newspapers.

INTERVIEWER: It must have been a very similar situation to the outcry when the *S4* went down. The Navy didn't have the capability to retrieve it.

CAPT MARTIN: It didn't have the capability, right. That was pretty close to when the *Challenger* and the *Columbia* went up. "What are you guys doing killing people?" The only asset, or capability, that the Navy had was the bathyscaphe *Trieste*. Of course, it had been down to 35,800 feet, so certainly, it could go down to the estimated 8,000 or 8,500 feet where they thought the *Thresher* was. That was true.

The only question was where the *Thresher* was. The bathyscaphe *Trieste* was not a high-powered propulsion system. We were not self-propelled on the surface and had to be towed to the dive site. When you pulled the plug and submerged to the bottom, you didn't particularly know where you were when you got to the bottom because of the water currents. We had a rudimentary compass on board.

Sears' best automobile batteries propelled us, and the electric motors had been built by General Electric and did work most times. But all the electrical wiring between the batteries, motors and control panels was going through electric wires exposed to salt water. Sea pressure at 8,000 feet, and we're talking about a lot of sea pressure there, pushes the water into any crack and any space, into the wires and shorts them out. Then, you end up with nothing. The other concern was about the search capability that we had. Underwater propulsion was about one knot in speed for four to six hours. That was it. Our sweep width, or how far we could see, was about fifty feet wide. That was looking out the forward porthole of the *Trieste*.

INTERVIEWER: It was visual.

CAPT MARTIN: Well, the thing was visual, yes. We did have experimental sonar on board. But that only worked intermittently.

INTERVIEWER: It was like looking for a needle in a haystack.

CAPT MARTIN: That's right. There were surface ships, four oceanographic research ships that had been sent to the scene. They were taking photographs of the bottom. They were taking samples of the sea floor to test for radiation or in some cases, dragging the bottom to see if they could pick up any debris. Some debris was found and photographed. But there was not enough evidence to say, "Here it is."

They kept us in port on standby in Boston until they thought they had enough evidence that was made it worth a shot to tow the bathyscaphe out there, 270 miles. They planted a deep-moored buoy, down to 8,400 feet or so. They used that as the marker out there, in the middle of the ocean. There was one Decca navigation line. Well, the hand-held sextant was still the primary tool for navigation.

It is hard now, forty years later, to think about how primitive things were. As I said, it was really the Wright Brothers stage of deep submergence. Don Keach, the officer in charge, talked with Captain Frank Andrews and said, "If you can get us an area that is about two miles wide, two miles across, we can go down and really, it's a matter of luck. It's as much a matter of skill as it is of chance." They towed us to sea. We started out on June nineteenth. We got there, I think, five or six days later. We could only be towed at a speed of about two or three knots. There was fog and a lot of delays. We got out there to the dive site. Don Keach made the first dive. He didn't find anything in particular. I made the second dive. I didn't find anything. I didn't see anything that could have been part of the *Thresher*.

INTERVIEWER: It was strictly visual.

CAPT MARTIN: It was strictly visual. We didn't have a road, you know. There are no roads down there. A road map wouldn't do you any good. All we had was this very simple compass. We were

not too sure where we were on the bottom. In other words, we couldn't come back. We had no underwater navigation system. We could not come back to a previous place.

We made five dives in that first series. After each dive, the gasoline from the maneuvering tank had to be replenished. The steel shot had to be replenished. We used about eight tons of steel shot on a dive. We descended through 8,000 feet, and that had to be replaced at sea. The bathyscaphe was moving up and down in the seaway, and the little Boston Whaler that was our transport between the dive site and the USS *Preserver*, the Navy salvage ship, our mother ship out there. Anything you're doing at sea is subject to the sea, the spray, and the waves. It's a wet operation.

After five dives, it appeared that we really didn't have much to show for it and decided to return to port, to Boston, to add more battery power so that we had more endurance underwater. The scientists from the Naval Research Laboratory, the electronics laboratory, and other laboratories, had put different sensors on board to detect anomalies. We had radiation counters, and things like that to detect any nuclear radiation. Nobody knew exactly what had happened. Did the submarine break up? If it did break up, what happened to the nuclear elements in the reactor? It was all unknown.

We were fortunate in that there were never any signs of any radiation above background. The subsequent dives that went on through 1993 never found any radiation above the normal background. We returned and got towed back to Boston. We had to go through the whole operation of unloading. Thirty-five thousand gallons of gasoline has to be pumped out. It was a big operation and took a lot of effort, a lot of hard work, a lot of coordination. The Boston Navy Yard was, of course, very cooperative. They had a lot of capabilities, but the bathyscaphe was a one-of-a-

kind, first-of-a-kind laboratory instrument. Everything that went into it was pretty much hand-made.

We prepared to go back to sea. One of the things that Keach had installed on the bathyscaphe during that in-port period was the mechanical arm that had arrived at our facility in San Diego in January of 1963. We had tried it out several times, and it worked well as long as you were on land and nice and dry. But when you put it in the ocean, it turned into a big battery. We sent it back to General Mills and said that they had to do a better job. They did. They did what they could, and it was then flown out to Boston to meet us there. It was reinstalled. It was a very good move on Keach's part to get that.

We went out the second time. It was the middle of August by that point. In the middle of August, off the Maine coast, off Cape Cod, the summer is over and the seas are starting to build up. We knew our days out at sea were numbered, in terms of the days that we could safely get from the salvage ship to the Boston Whaler and from the Whaler over to the *Trieste*.

Keach made the first dive in this second series. I made the second dive. We saw some things, and some things were photographed, like a six or eight-inch in diameter valve and other pieces of debris. There were places on the seafloor littered with something. We never did understand what it was. It looked like aluminum foil all over the sea floor.

On dive three of the second series, Keach happened upon a large area of crumpled steel, obviously from a ship or something. Remember, nothing said "*Thresher*" on it, so everything at that point was speculation or hope. There were large sections of steel. As he was moving around through that area, he had to be careful. You didn't want to get too near it. A piece of that steel could have punctured the thin skin of the bathyscaphe float. The float was about three millimeters in

thickness. You were very concerned over and careful about getting too close to anything that you might bump into, including rocks or something coming up or an underwater feature.

Then, Keach saw this pipe in this field and maneuvered over to it. He got the mechanical arm. There were five functions in the arm, like the shoulder, elbow, wrist, pinchers, and I think that only two of the functions were working. He got the arm through the soft ooze of the sediment, came up under the pipe and cradled it in the elbow. Then, he dropped it.

INTERVIEWER: The pinchers wouldn't work?

CAPT MARTIN: That's right. Then he dropped the steel ballast, the disposal ballast, to rise to the surface. He called ahead on the underwater telephone and said that he had a piece of equipment and was taking it to the surface. He said that he would stop at approximately one hundred feet below the surface. He wanted divers and radiation monitoring equipment down there.

We got ready, and they got a couple of the divers into the Boston Whaler, and I was there. I was the surface safety coordinator. It was after sunset by the time he told me that he was at one hundred feet.

INTERVIEWER: How long did it take him to surface?

CAPT MARTIN: Usually it took a little over an hour to come to the surface from 8,000 feet. It probably took him two hours that day, actually, because if had gone too quickly, the pipe might have become unbalanced in the arm and disappeared. He would have never found it again. It was a long time waiting on the surface. It was probably two hours. When he sent word on the underwater telephone that he was at a hundred feet, we told him to turn his lights on. Then, we could see the lights down there. We had to move around in the Whaler a little bit, but we did find the lights and the divers went down.

Johnny Howchen and Smith put a line around the pipe and brought it to the surface. The scientist was there and tested it for radiation. It wasn't anything above what you would expect. They surfaced, and life went on. That was dive three, and then, I went down on dive four. I didn't find anything spectacular. He went back down on dive five and didn't come across anything.

At that point, a big concern was the deteriorating hull on the *Trieste*. That is, the very thin, eggshell float that contained the gasoline. The gasoline provided the buoyancy for the steel float that the pilot and the observer went in. So the captain, Frank Andrews, and Keach talked things through and decided it was really a safety issue to get the bathyscaphe back to port before anything serious happened to it. There were some cracks in the iron float, but you couldn't do anything to repair those out at sea. You could put chewing gum in them or something like that, but then, when you towed the bathyscaphe in the seaway, there would be waves crashing over it. The craft would be physically warped.

Anyway, it was time to terminate the search and get towed back to Boston. That was what we did. They flew Keach to Washington to meet personally with the Secretary of the Navy, Fred Korth and the Assistant Secretary of the Navy for Research and Development was Dr. James Wakelin. They were very savvy and credible people.

The Navy was very fortunate to have people like them in those positions. Anyway, a couple of days later, the secretary held a press conference. At the press conference, he essentially said that the bathyscaphe had determined that structural pieces of the *Thresher* had been located, the pipe had been retrieved, and the pipe had the words "593 boat" and BUSHIP's drawing number etched into it.

INTERVIEWER: That was evidently the confirmation.

CAPT MARTIN: That was the confirmation for which everybody had been looking. The attitude until then was, “They found some junk in the ocean. What does that prove?” Everybody kind of had a big, collective sigh of relief, and the secretary closed it out by saying that this ended our operational search for the year, and that it would become a research project. We’d go back and check on it, he said.

Actually, the Navy sent us over to Marseilles, France, to discuss bathyscaphe operations with the other bathyscaphe in the world, the *Archimedes*, the French navy’s bathyscaphe. We exchanged a lot of information. But there wasn’t anything that they had that we could use to further our search. Our job was to get back to San Diego. The Navy wanted to build a replacement float. Mare Island Shipyard, in Vallejo, was selected as the building site.

Keach and I spent a good part of fall and winter commuting to Mare Island to give them the design specifications, and cooperate with the engineers and the workmen who were building the replacement float. The idea was a design that could be towed. The original bathyscaphe, built by Picard, had roughly a right-circular cylindrical design, which was inexpensive and efficient for containing the gasoline.

We wanted something with a slightly heavier-gauge metal, and we wanted the batteries in a safer position, not in aluminum cans on top of the light aluminum deck of the *Trieste*. We were trying to get better electric motors. The bathyscaphe, the new float, was transported to San Diego, and the Navy Electronics Lab had a nice ceremony for bringing in the new float and putting it into the water. It was very nice. Then, the work began to assemble the new float with the old sphere that we were using for the science and search operations. They got that together.

Then, Brad Mooney’s new team came on board to relieve Don Keach. Larry Shumaker came back to the project to relieve me as the assistant officer in charge. They assigned a third

officer, John Howland, because there was plenty of work to do. They increased the allotment for enlisted men. It went from about eight up to a dozen or so. We were getting a lot of support.

Keach was detached. We were ordered and sent from San Diego to Boston to start a second summer of search operations. I was there and helped them get ready to go back to sea. When they left port, I was detached and went back to San Diego, or was detached from the bathyscaphe project and went back as the Executive Officer of a submarine down in Key West, Florida. Brad Mooney will tell you the rest of the story. The highlight of that was that on their dive, they actually landed on one of the pieces of the large hull section of the *Thresher*.

INTERVIEWER: Sounds great. Thank you for that. That brings that story to an end at the right time.

CAPT MARTIN: Good timing, huh? I appreciate you going out and walking with me.

INTERVIEWER: This is nice, yes.

CAPT MARTIN: The really important thing that came out about the tragedy was an explanation of the causes of the disaster. What could we do about it? Several groups were formed on the engineering side and the operational side. What happened? Two well-documented and important papers were the Findings of the Naval Board of Inquiry and the Hearings of the Joint Committee on Atomic Energy.

Those are summarized in Part Two of the Naval Submarine League article I wrote. Part One essentially tells you what I just went over here, in terms of the operation on the search itself. The Deep Submergence Systems Review Group came up with a lot of good ideas. They came up with some really clever, innovative ideas. The preeminent one of that was the deep submergence rescue vehicle (DSRV), a vehicle that could go down to the submarine if it was at 2,000 feet or less. That

would be within the structural strength of the hull. There was hope of recovering personnel from a downed submarine. They actually went out and awarded a contract and had two of these built.

The concept of operation of the DSRV is to fly the DSRV to an airfield near a port where a specially equipped submarine would carry it piggyback on top of the deck. The submarine would submerge and transport the DSRV to the sunken submarine. The DSRV would evacuate the crew from the submarine and return to the transport submarine. The entire operation from port to return to port would take place submerged. This avoided the dangerous air-sea interaction that can damage the DSRV or the transport submarine or cause delay in the operation due to bad weather. The men in the downed submarine had a limited number of days before the oxygen became depleted or the partial pressure of the air mix inside the submarine caused it to become toxic. Time is of the essence.

Fortunately, they've never been used in anger, so to speak, or in an emergency. They have gone out for training exercises from time to time. The DSRV-1 was put into service in 1970 and DSRV-2 in 1971. They are now thirty-plus years old. There were maintenance problems, since everything on the DSRV was pretty much one-of-a-kind when it was built. Now, thirty years later, do we have the capability to maintain them? In some cases the answer is "No." and of course everything today costs more. I only have unclassified knowledge about what the Navy is up to. I don't have any special access or anything.

As far as I know, DSRV-1 is essentially out of commission already. The second one will be deactivated, or at least no longer funded in 2005. After that, they will use a submersible suit that each crewman would put on. It is a combination Steinke hood and life preserver. Each crewman would pop to the surface in an individual suit. It would keep them dry on the surface.

Of course, there is no point in popping up to the surface if the water temperature is forty degrees because you are only going to live a few minutes anyway. They are certifying those suits down to about 600 feet, so that is on the shallow end. On the deep end, they have a new system, but it's not a deep submergence rescue vehicle. It is transported to the site on a surface ship, or a ship of opportunity. It will be unmanned, except for a diver. It'll be totally controlled as a remotely operated vehicle (ROV) controlled by people from the surface through sonar and underwater television cameras that locate the submarine and maneuver the ROV to it. Then, the diver will visually check what's going on in the submarine. He can open a hatch, possibly, and at least check if there is water or air inside, and that kind of thing. That is in development. It's supposed to be out in a year or two. We certainly wish them good luck with that.

INTERVIEWER: There seems to be a big controversy between what the DSRV had, not having to worry about the air/water interface, and the remote vehicle, which does.

CAPT MARTIN: You must go back and rediscover the problems with working on the surface of the sea with something that is 1,000 or 2,000 feet below. That's why I say that what we learned on *Thresher* was that it's dangerous and sometimes impossible to operate from the surface. It's difficult to be towed to the site, as opposed to being delivered on a submarine, which can put something piggyback on the exterior and take it there at maybe 15 knots.

The *Trieste* got towed at two knots. All I can say about the hard work that went into the DSRV operation is what are the lessons learned? You want to do it underwater. Avoid the sea/air interface. Avoid decompression sickness of the crew, assuming you got there in time. Just avoid all the problems of working on the sea surface, which is just a very severe operational environment, even in good weather.

As I said, why they went back to that, it is not clear to me. I guess they wanted to save money or something. I wish them well with it because it doesn't seem to be moving forward. The operational concept is with what I disagree. The technology is probably great. I am sure it is great, actually. They spent good money on it, and that part of it will work. But whether the weather, the ocean, and the location will cooperate with you remains to be seen.

INTERVIEWER: It sounds like the Navy has a short memory for lessons learned.

CAPT MARTIN: Well, it's been forty years. If you think of it, a Navy career is twenty years. That's two full careers for a twenty-year officer or enlisted man. That's what you lose in that time span. They have a Sub-Safe Program today, and those submarines are very, very safe. They essentially don't let salt water into the ship, or not very much of it.

But in terms of the rescue operation, of course, we've come a long way with saturated diving and can do wonderful things. I'm just saying that if I had the money, I would certainly build and improve, or at least use, the operational concept of take-it-underwater, perform the rescue underwater. Return the rescue vehicle back to the submarine. Eliminate all of the safety concerns that you have when operating from the surface.

The other thing is this ship of opportunity. Back at that symposium in 2001, there was a retired chief warrant officer who was still working in the commercial world. He said, "ship of opportunity," yes. "But having a captain on there who could lay a moor, a four-point moor in 1,000 feet of water," he said, "I doubt if one in one hundred of those skippers has ever made a moor in one hundred feet of water." This was a man from the commercial diving industry who was familiar with not just the technology. Well, we're still dealing with humans here and they have to have a certain amount of training to do this. Otherwise, every operation and every emergency is relearning, retraining of a new crew and skipper. You are trying to do this four-point moor, or even

a three-point moor out in a seaway somewhere. God forbid it be someplace in the Persian Gulf. If you're doing that on the surface, you're going to have a lot of unfriendly people around there trying to make it more hazardous for you. Those are my opinions. Again, I don't know all of the classified plans and things like that.

The other thing we learned on the Palomares bomb operation was that you had to keep the curious, as well as the menacing, at some distance. Everybody's got these mini-sub and ROVs now. Eight new nations, Asian nations, bought diesel submarines in the last four years. There's going to be a lot of company out there, and they may be unfriendly.

INTERVIEWER: I wonder if I can ask, since you've obviously had a very exciting career, could you talk about anyone that you would consider a role model or a mentor in your career?

CAPT MARTIN: I had 12 years of active duty, and then, I left active duty and went to Reserve. There were a few people who made big differences in my life. My first skipper, Gene Farrell, Rear Admiral, retired, was one person. He has certainly done a lot for me, personally, and in every way. Don Keach, who was the Officer-in-Charge of the *Trieste*, was a mentor. He looked at me and gave me a couple of hints as to how to be more effective. He did help me out. Brad Mooney, who followed me on the *Trieste*, was another. But because I was still in the deep submergence world when I left active duty for a couple of years, I was working for Lockheed. Brad was still in the Navy. He was able to guide me and provide opportunities. Not that I was always able to take them. But he was always opening doors and things like that. Of course, John Craven was another individual who influenced me. John and I were good friends. He was not an operator, but he understood a lot of what was required, like what kind of people you needed and so on. Al Vine was important, too. Al Vine had come out to visit us on the bathyscaphe. Of course, the ALVIN was just on paper then. He'd say, "George, this bathyscaphe thing you have here, this is not a submarine.

This is something that needs to be loved and taken care of. It needs to be nurtured, and you need to be really personally involved with it.”

Craven was moving in much higher circles, and he tried to guide me when I left active duty. You know, I didn't pay attention. But we're still friends. It was a long time ago, and I never looked back. That's useless. I had a good working career, and the Navy experience was wonderful. The Naval Reserve worked out for me very well. I was the reserve Commanding Officer of two submarine tenders. If the balloon went up, and in the 1960s and 1970s, that was still a pretty high expectation, that I would have become CO of a 1,000-man submarine tender. That was good. I did get promoted to Captain. That was great. I started my own company called Project Engineering, Inc. in 1977. We worked mostly for NASA and the Goddard Space Flight Center. We closed in 1994, and I've essentially been retired since.

It was the American Dream, to own your own business and that kind of thing. I just feel very thankful for all the opportunities that have been given to me, like the good people I met. There are lots of people that you never hear of. This one officer who ought to be interviewed is ‘Ski’ Dzikowski. Captain Dzikowski, who lives over in Baltimore suburbs. He was at the symposium. He was an engineering duty officer. He was in charge of the deep submergence on the ship side for several years, from 1967 to the early 1970s or so. He knows everything. He’s got a sharp mind and is a good man. There were a lot of good men. There was Pete Palermo, whom I talked about earlier. He was a civilian engineer. He's still alive. Most of the others are dead by now, like B. King Couper who was our sponsor at BUSHIPS. A lot of them, like Keach, are gone. Andy Rechnitzer has been a good friend. He was chief scientist on the *Trieste* during the deep dive. I actually interviewed with him when I went through to the *Trieste*, and he then left and went to industry to work for North American Rockwell and helped them build a submersible called the

*Beaver*, which was headed for the oil fields to work underwater. Andy Rechnitzer is still alive and in San Diego. There were a lot of good people.

Swede Momsen was another great man as well as Frank Andrews from over in Annapolis. Of course, I did not continue in that world after I left Lockheed. I ended up in the NASA world, which was very different, but I appreciated the chance to come back.

In 1997, I started wondering about who remembered the *Thresher*, what the lessons learned were, and what they were doing about it. I got an invitation to speak to the Washington section of the Naval Submarine League. They were pleased with that. They invited me to speak to the national meeting that they hold in June in the Alexandria area.

That led to the two articles that were published by the Submarine League Review. The first one, actually, won best article for last year. I would just love that the people who are not too senior that they can't involved in details, but are senior enough to put an order in, to say, "Look, this is what we learned forty years go. Let's re-work that and see if we can't benefit from those lessons, or at least have a better understanding of why those lessons are no longer valid."

Of course, in the Navy, everybody's moving around, so it's very hard to get in touch with those people. Things are a lot more complex now. There are lots more layers with which to deal and safety requirements and things like that. We were fortunate that we all survived it, but we weren't impeded. We could do anything we wanted to do. It was up to you to weigh things and act accordingly.

INTERVIEWER: I think this is probably a good time to stop.

CAPT MARTIN: Sure.

INTERVIEWER: I want to thank you, George, for the interview. I certainly have a lot to reflect on from your career.

CAPT MARTIN: Thank you very much.

INTERVIEWER: You have a very, very exciting background.

(Whereupon, the INTERVIEW was concluded.)

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

ORAL HISTORY OF THE MAJOR PARTICIPANTS  
IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS

INTERVIEW OF GEORGE ROCECK

## PROCEEDINGS

INTERVIEWER: What I usually do is something rarely simple. What's your full name?

MR. ROCECK: George Roceck.

INTERVIEWER: How do you spell Roceck?

MR. ROCECK: R-o-c-e-c-k. Of course, I have a nickname.

INTERVIEWER: What's your nickname?

MR. ROCECK: It's 'Moon.'

INTERVIEWER: How did you get the name Moon?

MR. ROCECK: Well, I got it twice, once when I was about six years old with the old gang, growing up. Every summer they used to shave our hair off. This particular time, we were all sitting on a curbstone. When the streetlights first came on, if you didn't say, "Pass it up," you were the guy that got the lumps. But anyway, when the lights came on, the light would shine on my dome head. Pixi was the leader of the gang. He said, "Oh, look at that. It looks like a moon shining there." That was the way I got a nickname, Moon. That was the way I grew up. Later on, my mother and dad would sometimes call me Moon. Then, I got the nickname again on the USS *Sculpin*.

INTERVIEWER: How did you do that?

MR. ROCECK: I used to sleep in the torpedo room. I came back one time from liberty, and I stripped. I was laying in my bunk naked, laying on my stomach. Old Clark, the electrician, came in off of liberty, and he was feeling pretty good. When he opened up the door, we had a night blue light, and it was shining on my rear end. He was telling the guy the next day that when he opened up, there were these cheeks. He said that it looked like a moon coming over the mountain. He

called me Moon, and I didn't say anything. This went on for several months. Then, the name caught on, and everybody started calling me Moon on the *Sculpin*.

Finally, I told Clark. I said you won't believe this, but I had that nickname from the time I was six years old. I told him what occurred. I said, "I'll tell you what, Clark. The very next letter I get, I'm going to let you open it." The next letter I received, I gave to Clark. I said, "You open it and see what the heading says." My sister always wrote me. Sure enough, when he opened the letter, it said, "Dear Moon." Then, he believed me.

INTERVIEWER: When were you born?

MR. ROCECK: I was born the 29th of April 1921 in Cicero, Illinois.

INTERVIEWER: That was a wild town.

MR. ROCECK: Oh, yeah. That was Al Capone's stomping ground.

INTERVIEWER: Did you have any problems growing up there?

MR. ROCECK: Well, I mean, they had control of the town just like they did Chicago. They had their houses and everything all sewed up.

INTERVIEWER: Did your dad work for him?

MR. ROCECK: No. My dad was a tailor. He had a little shop. It was about three doors down from the local gambling club. I used to work at a gas station on the main drag, which was the same distance, three blocks away from the gambling club. A lot of them used to come over there with their cars to get them serviced. I stayed around. I got to be a teenager. It wasn't only me, though. There were other teenagers. There were two others who lived in the area. We used to work and hang around that gas station. We would deliver the cars. Of course, we looked forward to that because it gave us good tips. Moreover, you could work all week at the gas station, but if you delivered one car, it'd pay for the whole week's wages.

INTERVIEWER: That was big money. When did you join the Navy?

MR. ROCECK: I joined the Navy on June 6, 1940. I wanted to join earlier, but I had a tooth problem. They wouldn't accept me until I got that tooth repaired. I did. A dentist lived right across the street from the gas station. He used to come over there. I asked him if he could repair that for me, and he did. Then, I went back to the Navy. They accepted me, and I went in.

INTERVIEWER: Why did you want to go in? It was peacetime.

MR. ROCECK: Well, I was looking for excitement. I had a little bit of the wanderlust. When I was 16, a boyhood friend of mine, who lived down the block from me, and I thought we would leave home and go out to California and make our fortunes. As it happened, we got to Salida, Colorado, in the gorge, and it was colder than heck. We almost froze. We got into this town at about two in morning, and it was cold.

INTERVIEWER: You were hitchhiking?

MR. ROCECK: No. We were riding the rails, riding the freights. We thought we had it figured out right. April was nice back in Cicero, but man, it isn't nice out there in the west yet. We decided, "Well, the heck with it; let's turn around and go back home, which we did." But that was a good experience for us. We learned how to swallow our prides. We ran out of money. When you got hungry, you went in and begged for food worked for it.

INTERVIEWER: Did you do that at homes?

MR. ROCECK: We had to do that at both homes and businesses, sure.

INTERVIEWER: It's funny. In those days, that was acceptable. Today, it's a big racket.

MR. ROCECK: That's right. In those days, there were some who had college educations, well-educated men on the road. But they treated us just great. They gave us the ropes and told us where to get these trains, what cities to watch out for so that you didn't drop off too late in the city. They

had those railroad digs there, and some were pretty mean. They gave us a good education on what not to do, which was great.

INTERVIEWER: You were in the late teens at that time, weren't you?

MR. ROCECK: Yes. Sixteen we were. It wasn't that we left home because our homes were bad. We had perfectly good homes.

INTERVIEWER: Did your parents know that you were going to take off?

MR. ROCECK: No. None of our parents knew we were going to take off. We just left a little note, and we left.

INTERVIEWER: But you were walking when you got back.

MR. ROCECK: Oh, sure, we were walking because they were glad to see us.

INTERVIEWER: Alive.

MR. ROCECK: You're darn right. Of course, in those days, you didn't have all that funny stuff happening.

INTERVIEWER: Did you have to wait until you were 18 to sign up?

MR. ROCECK: Yes.

INTERVIEWER: You had to wait until you were 18, then you enlisted.

MR. ROCECK: Yes.

INTERVIEWER: Did you know there was a war coming on?

MR. ROCECK: No.

INTERVIEWER: Where did you take boot camp?

MR. ROCECK: I went to the Great Lakes Training Station. I signed up for six years right off the bat. They brought us up by train from Chicago. The Great Lakes is only about 45 miles north of Chicago. Our first meal was on Saturday morning, and it was beans, baked beans. I'd never heard

of that, eating beans for breakfast. When I got through that line and saw those baked beans being put on that silver platter, my heart just went. I said, "Oh, Lordy. What did I sign up for, eating beans for breakfast?" But in my later naval life, I enjoyed those beans. They were just great. Of course, when you were eating those kinds of beans at a big base, they were not as good. On the submarines, they were ten times better.

INTERVIEWER: You just signed up and went through boot not knowing what you were going to end up doing though, did you?

MR. ROCECK: No. We got through the training, and they came with the request that anybody wanting to volunteer for the submarine course to sign his name on the bulletin board.

INTERVIEWER: How long was boot training?

MR. ROCECK: Boot training, I think, was three months at that time.

INTERVIEWER: But in submarines, you knew that made more money, though, right?

MR. ROCECK: Well, I didn't know that at the time. But to me, it was another exciting way to go. I signed in for it, and then they examined us. We had to go for examinations. The closest buddy I had in that training period was not passed on account of some kind of obstruction he had in his nose. I was accepted, and the training station sent us to New London, Connecticut, for submarine school, and I went through that.

INTERVIEWER: How long did that last?

MR. ROCECK: That was another three months, I think..

INTERVIEWER: What did it consist of then?

MR. ROCECK: Well, it was mostly classroom work.

INTERVIEWER: It was technical.

MR. ROCECK: Yes. We studied the electrical, trend and air systems. Then, they would take you, periodically, on a regular submarine, which were the old R boats and S boats. They would take you out for the day, and on board, they would assign you different positions. Of course, they would have the regular crewmembers there to explain what, when and why to do things. They would be watching you.

INTERVIEWER: Was claustrophobia a factor with some of the other guys?

MR. ROCECK: Yes. There were those who sometimes wanted out. Of course, there were some there, too, who were dropped out. They couldn't go through the pressure tank. They'd go up to a hundred pounds of pressure on that. They took it easy. They boosted the pressure up in a slow matter, and anybody who had a problem would raise their hands. Then, the guy said, "Try and pop and your ears or chew," and all this. If you could do that, then he would increase the pressure. But if somebody couldn't handle it, he would drop the pressure and that person would be taken out of the tank.

INTERVIEWER: You survived all those tortures then.

MR. ROCECK: Yeah. Then, we went through the tower with the lungs.

INTERVIEWER: You used the Momsen lung.

MR. ROCECK: They showed us how to use that. After you graduated, they sent most of us to the West Coast. I went to San Diego. When I arrived there, I was transferred to the *Sculpin*. That was in November of '40.

MR. ROCECK: Then, the *Sculpin* went from San Diego went to Mare Island to the navy yard. Overall, that was three months. From there, she was sent to Pearl Harbor for duty.

INTERVIEWER: What task did you end up doing on the sub, on the *Sculpin*?

MR. ROCECK: When I first went on her, I was a seaman. I was doing topside work, deck work. I stayed as a seaman until well after we got to Pearl Harbor. Then, I wanted to go into the black gate, the engine room. They eventually transferred me when there was an opening. They put me in the engine room, and that was where I stayed for the rest of my Navy career, as an engineman or a motor-mac. At that time, it was called a motor-mac.

INTERVIEWER: You were really learning a trade, though, on top of that.

MR. ROCECK: Yeah, right. Well, the reason I wanted to go into that end of it was because when I was a kid at the gas station, I learned a lot about working on engines, cars. I kind of liked that, and that was the reason I put in for it.

INTERVIEWER: You were one of the motor-macs on the *Sculpin*. You were one of how many guys, about three or four? You went there by yourself?

MR. ROCECK: In the black gate? Oh, no. I think we had about 12 or 15 men in the black gate.

INTERVIEWER: There was that many?

MR. ROCECK: Sure.

INTERVIEWER: This was the diesel, diesel-electric.

MR. ROCECK: That's right.

INTERVIEWER: That was kind of a hot, noisy, smelly place.

MR. ROCECK: It sure was, yes.

INTERVIEWER: How did you hack that? You just did it.

MR. ROCECK: You just got used to it.

INTERVIEWER: Do you remember the name of the first skipper you had?

MR. ROCECK: The first was Wilkins. Wilkins got transferred during the time we were in overhaul at Mare Island. Then, we got another skipper. To be honest with you, we hadn't been able to find out what his name was because he was only there about three months.

INTERVIEWER: You had a third skipper.

MR. ROCECK: When that skipper was relieved, in Pearl Harbor, we got Lucius Chappel aboard. In fact, George Brown is going over to get Phyllis Chappel. She's a widow. She'll be over there. Chappel stayed on there for eight runs.

INTERVIEWER: Wow. Do you mean eight patrols?

MR. ROCECK: He was on for eight straight patrols, right. I think he was the only skipper who did that.

INTERVIEWER: From Pearl, where did you go?

MR. ROCECK: Well, we stayed at Pearl until 1941, when we got orders to go to Manila.

INTERVIEWER: Manila, of all places.

MR. ROCECK: Yeah. That was around September or October, I think, that we went out to Manila.

INTERVIEWER: You had no idea about the Japanese war or anything?

MR. ROCECK: Well, we were told that things are getting a little tense down there when we were in Pearl. That was the reason that we were being transferred to Bolster with the Adriatic Fleet. That was where we went.

INTERVIEWER: You were fully armed then, torpedoes and everything.

MR. ROCECK: Yes. We were fully armed. We took on more chow than we would normally take. The officers wouldn't tell us where we were going. I think it was because the skipper figured it'd be better for the crew's morale to let them guess. There was a lot of talk going around: "We're going

to go here. We're going to go here and there, to Australia and China.” I guess that in a way, it was good for morale. But when we got past Guam and started in a certain direction, then the quarter ---- said it was either the Philippines or China. We kind of narrowed it down between those two places.

INTERVIEWER: Were you traveling on the surface?

MR. ROCECK: We were traveling both on the surface and underneath, yeah.

INTERVIEWER: Did you do any test dives or anything?

MR. ROCECK: Oh, yeah. We always did that. You burned fuel, and you had to go down and re-trim your vessel, you see?

INTERVIEWER: That used up fuel.

MR. ROCECK: Right. That was because you were taking on salt water to dispel that fuel, so you were getting more weight.

INTERVIEWER: When did you get into Manila, then, about September or October you said?

MR. ROCECK: It was right about then, yeah.

INTERVIEWER: Did you stay there? Were you stationed there?

MR. ROCECK: Yes. We were stationed there. I think we weren't even there a month, and we got orders more individually, more as a nest. That was another thing giving us a little indication that something was going to happen.

INTERVIEWER: Why didn't they do that with the planes in Pearl Harbor?

MR. ROCECK: That's a good question. From what I read, the admiral in Pearl Harbor wasn't getting all the information that was given to Admiral Hart, out there in the Philippines. I think he was made a scapegoat, but I don't think it was his fault entirely.

INTERVIEWER: I don't think so, either. Where were you on December 7, 1941?

MR. ROCECK: I was still aboard. It was the wee hours of the morning when they gave us the word that Pearl Harbor was bombed.

INTERVIEWER: Actually, that was December 8th for you guys.

MR. ROCECK: Yeah, I think so. Then, we took on more supplies, and we were getting ready for war patrol. I don't remember on what day we left.

INTERVIEWER: How many other boats were there? Do you remember?

MR. ROCECK: Oh, gee. We were one squadron there. We came there in the fall. I think about a month later, another division came out there, with six boats.

INTERVIEWER: That's probably well documented anyway.

MR. ROCECK: Yeah.

INTERVIEWER: That was your first real war patrol.

MR. ROCECK: That was our first war patrol, right.

INTERVIEWER: What were you looking for?

MR. ROCECK: Well, we were looking for whatever, but we were keeping an eye out for transports, primarily. They were afraid of the Japanese troops making a landing on the Philippines. We were fortunate. I think we were out there two or three weeks, and I think we sank one or two.

INTERVIEWER: Did you really?

MR. ROCECK: Yes. The transports had Japanese soldiers on them. The Philippine government gave us the citation for doing that. All the other boats that sank something during that period of time got that. I don't have it here. It's got that gold bar and the blue inside, but it's a gold outline.

INTERVIEWER: How did you feel, sinking a ship like that? You were just part of the team that did the job, but did you feel elated?

MR. ROCECK: Absolutely. I mean, we knew it was war. Heck, we were doing anything we could do. When we heard that explosion, it was great.

INTERVIEWER: You probably weren't out terribly long, then, were you, on that first patrol?

MR. ROCECK: Well, I think we were out there about sixty days, maybe not even that long. But we worked our way on down to Borneo. We went in at Balikpapan to get refueled. That was an experience. We picked up a pilot on the outskirts, and the pilot took us inland to get refueled. It looked like a small river, but it was deep because that was where all their oilers were going in to get refueled. I went up to the control room, and I could hear that Dutch pilot giving orders to the helm, "Left a bit, steady. Right a bit, steady." Well, it looked to me like he could spit on both sides. It was that narrow of a river. It was just jungle, just jungle. Normally, you would hear the pilot give orders, "Left five degrees rudder and steady. Right two degrees rudder." For this, that did not happen. It was left to right, left to right. It wasn't that much to be maneuvering, but he kept it right in the center. We went there at nighttime, all night. We tied up there. Boy, that was good fuel. My gosh, that was the best fuel. It was better than even our fuel in the States.

INTERVIEWER: It was still diesel fuel, only better refined.

MR. ROCECK: We had filters that looked like cream separators on a farm. That was what we used to purify and lube our oil. But we would have to clean that purifier. It was a standing order, anyway. Every four hours, you'd clean that sucker. It would get some dirt in there. But when we used that oil that we got from Borneo, my gosh, sometimes you could run through a day, and there would be nothing in there. It was fantastic. Of course, later on, when we took on another load in Nesmith (sp) Bay, in the Gulf, it was like tar. My God, you had to clean that thing about every one or two hours. You had to take that thing apart.

INTERVIEWER: I think it was getting to a point at which you were lucky to get any fuel at all.

MR. ROCECK: Oh, yeah,.

INTERVIEWER: After that, did you go out on what you could call a second patrol?

MR. ROCECK: No. We were forced out. As the Japanese were advancing, we were forced out. Then, from there, we went into Saribaya and Jabba . That was a Dutch naval base. We stayed there seven days.

INTERVIEWER: I would have thought you'd been bombed.

MR. ROCECK: Well, they were bombing Borneo too, Balikpapan, see?

INTERVIEWER: They weren't bombing while you were there.

MR. ROCECK: No. It was not while we were there. But they had bombed that area. We figured, as they were getting closer, they would be bombing more frequently. Well, it was the same way with Saribaya. While we were there for them, for seven days, we didn't get bombed, but it was only a few days after we left that they did get bombed.

INTERVIEWER: Man, you were one jump ahead.

MR. ROCECK: Yeah, right.

INTERVIEWER: The other problem, I understand, was that the torpedoes weren't too reliable.

MR. ROCECK: That's exactly right.

INTERVIEWER: Is that what happened to your boat?

MR. ROCECK: Yes. All the boats had the same problem, and god darn fish. From what I understand, when that torpedo hit perpendicularly, the firing mechanism folded up some way.

INTERVIEWER: It was really too far forward of the fish.

MR. ROCECK: I don't know exactly. But if you hit that on an angle, that torpedo would explode. It would allow that to fire the torpedo. But when it went directly in, something folded before it ignited the igniter? I'm not too apt on that.

INTERVIEWER: Well, on some of your patrols, you made a run and hit the target, but it wouldn't explode then.

MR. ROCECK: That's right. We were not the only boat. All the boats were having a problem. Also, the fish were running more deeply than what you set them at. That was another problem. They had two problems with those torpedoes.

INTERVIEWER: You had no way of really knowing at your end.

MR. ROCECK: No. Admiral Lock, after he was getting all the complaints from skippers, set up a net. I believe it was in Kurt. Then, they had one of the boats prior to the fish, and when they raised the nets up, they found out that, yes, the fish were running more deeply than what you set them at. Even the admiral was having a hard time trying to convince those people in Washington, D.C. that there was a problem. They wouldn't admit to it.

INTERVIEWER: You said you were on eight patrols.

MR. ROCECK: Right. It was on the ninth one that we were sunk.

INTERVIEWER: Do you want to go through all the patrols? Did anything unique happen on each one or what?

MR. ROCECK: Well, I can't even recall what happened on a lot of them.

INTERVIEWER: You ended up back at Pearl at a lot of times, didn't you? You got kicked out.

MR. ROCECK: Yeah, we went back to Pearl. In fact, when we went back for our overhaul, we went to Pearl. We also operated out of Midway one time.

INTERVIEWER: Why don't we get up to the ninth patrol? Where did you leave from?

MR. ROCECK: We left Pearl, and we were to operate between the Marshall and Gilbert Islands and Truck Island. I think they were going to make a landing on the Marshall or Gilbert islands, and they wanted the submarines to be between the two islands. We were supposed to all collaborate.

That was when we got Captain Cromwell aboard the *Sculpin*. He used to handle the wolfpack. They were going to try that wolfpack setup like the Germans used.

INTERVIEWER: Was he a pretty good skipper?

MR. ROCECK: He was the division commander. Conway was our skipper. That was Conway's first command. After the eighth run, Captain Shackwell was relieved, and we then got Captain Conway. Then, Captain Cromwell came aboard to take care of the whole wolfpack signal.

We spotted one convoy, and the skipper wanted to make an end around. When he made an end around, his approach didn't work out the way he wanted it to. That was what he was going to do. When he didn't make his original, he decided to make an end around and get ahead of the convoy, which we did. But they left the sleeper way back. When we got up to the surface, that destroyer was all the way in the back. It came up on us and its lookout spotted us, so then we had to dive again.

INTERVIEWER: That was what you called a sleeper. He was waiting just for you guys to play your game.

MR. ROCECK: Sure. The convoy went on by, and we thought that was fine, but he was way behind them, see? Then, when we came up to go around, he got right on us. The bad thing in that particular area was that the water temperature was constant all the way down. Often, you got different temperature water, what they call a 'gradient.' Well, if you found one like that, fine, because when you were below it, and he sent a sonar signal, if it hit the gradient, it had a tendency to bounce off. It gave a false reading. But when you had the water temperature constant, and he sent that beam down, boy, he had you dead right. That was what happened there. The water was a constant temperature. We had a heck of a time trying to get away from it. We finally did, in the rain scrawl.

INTERVIEWER: The depth charges were coming down at you then.

MR. ROCECK: No, not yet.

INTERVIEWER: Oh, but you could hear the ping.

MR. ROCECK: Yes. We could hear that pinging. Then, when he got close enough, he started sending his depth charges and kept working us over.

INTERVIEWER: What was it like, to be depth charged?

MR. ROCECK: Well, let me tell you, we were all scared. Don't let anybody tell you that no, they weren't. We were all scared. With us old timers, though, you couldn't afford to let the fear show on your face. Although we were young kids ourselves, we had younger ones with us, and they were watching us. You could not afford to show the fear. But you knew you had to do certain things, and that was it.

INTERVIEWER: I assume the boat just shook.

MR. ROCECK: Oh, sure.

INTERVIEWER: Any leaks?

MR. ROCECK: If you had bulbs or anything, it just shattered the bulbs. The cork that you had would crack and fall down. Lockers would pop open.

INTERVIEWER: Was it noisy?

MR. ROCECK: Oh, yeah. You would hear a click first. After you heard that click, you knew that that thing was going to woof.

INTERVIEWER: You didn't know how close it was going to woof, though.

MR. ROCECK: That's right. When that can came over, you could hear the propellers. Of course, when that 'chu-ga-da' faded, you knew they were going to come down. Then it was click, click, woof! That was why I say we were all scared. But, hey, you had to keep your wits about you

because everybody depended on everybody else. If anything occurred out of the ordinary, you had to take care of it the best way you could.

INTERVIEWER: I assume part of the training on a boat was that you had to know more than one job.

MR. ROCECK: Sure. That was your qualification. They gave you a year to qualify on a submarine. You had prints, manuals and drawings that you had to make, like the fuel system, electrical system, trend system, drainage system and air system. Also, you had to go to each compartment and learn that compartment. The man in charge of that compartment, like an after torpedo room, the senior man had to initial your paper. If he felt that you knew that compartment, he would initial your paper. But if you didn't know it, he would never initial it. You had to learn every compartment the same way, with the senior man in charge of that compartment. Once you got them all signed, the chief of the boat would take you through. He'd ask, "What's that valve for?" or "What's that line?" or "What's this? What's that?" If you didn't know it you had to wait until you learned it. Then, if he OK'd you, you went through with the engineering officer. The engineering officer would take you through the boat and grill you. Then, if he passed you, you went through with the executive officer. If the executive officer OK'd you, he then qualified you in submarines. That qualification assessment was put in your record, and you then got your extra money. You always got, I think, five dollars a month. But if you got qualified, then you got a little more. I forget what it was, fifteen dollars more or something like that. They gave you a year. If there was a guy who was a little slow in learning but showed that he was trying, they went beyond a year. But if it was a wise guy or something like that, someone who wasn't trying, they would drum him out of the submarine force. They didn't want that guy.

INTERVIEWER: If something happened to the boat, you could jump in almost any compartment.

MR. ROCECK: Sure.

INTERVIEWER: On the ninth patrol, you were being depth charged quite heavily.

MR. ROCECK: Yes.

INTERVIEWER: Did that bring you to the surface or what?

MR. ROCECK: Yes. Eventually, as we were coming up, the darn depth stuck. Normally, if you attacked that gauge, it would free up. Now, I don't know if that diving officer -- I guess he did, but that gauge didn't want to move. The first thing you knew, we broached. In other words, we came to the surface. When we came to the surface, the destroyer spotted us again. Although we got down below again, it knew where we were. It never let loose after that. He just kept depth charging us until we couldn't stay down any longer. We were taking on too much water.

During the depth charge attack, I was in the forward engine room. That was my duty station. I heard this water just come gushing in. I went up to the forward part of the compartment, and I looked down. Where the piping through the hull was fastened to the coolers, the flanges, it looked like someone took each nut and unscrewed it about an eighth to a quarter of an inch. Apparently, what happened was that it stretched; it flexed that hull. It was so close, and it stretched out. Actually, all those bolts and nuts that were holding the plane together, they were loose. The water was spraying out between the flange basin.

INTERVIEWER: Like finger ----.

MR. ROCECK: That's right. That was when I called the control room and reported that we had serious leaks in the forward engine room cooling system piping. I figured the compartment was flooding in about 15, 20 minutes. Of course, I presume other compartments had serious problems also, but that was what happened in my compartment. I think that was one of the factors that led the Skipper to decide to battle surface.

INTERVIEWER: What was your rating at that time?

MR. ROCECK: I was a first class motor-mac.

INTERVIEWER: You did surface?

MR. ROCECK: Yes. We surfaced, battle surfaced. After we battle surfaced, the skipper passed the word, "Abandon ship." Things were getting pretty hectic. I didn't really want to leave because we went through a lot of this stuff before and got away from it. Of course, this was worse. Swift, he was in the maneuvering room on the electrical controls. I went back there several times. Some of the men were cracked out from the heat exhaustion. They were just lying on the deck, unconscious. I told Swift that they had passed the word, "Abandon ship," and I said, "We had better get out of here." He said, "Okay. I'll be coming." We had a hatch in the forward engine room. Gee, when I got up to the top, there was a guy sprawled out. I don't even know who he was, but there was a mess of blood. I dropped back down.

INTERVIEWER: You figured that he got shot.

MR. ROCECK: Yeah.

INTERVIEWER: Did you think the bow was being strafed?

MR. ROCECK: Sure. I guess they were firing everything at us. When I finally decided to leave, I decided that when I got up there, I was going to run towards the conning tower and get behind either side. I finally did. I got up there. I started looking around where that can was. Well, it was on the same side as I was. There was a belch of fire coming out of that. They were firing everything. On that boat, you had what was called a 'dog house.' You could go from one side to the other, and it was just an opening.

INTERVIEWER: Right. It was after the conning tower.

MR. ROCECK: Yes. They called it the 'dog house.' Well, I got halfway through, and that was when we got a direct hit into the conning tower. It just stunned me. I mean, I just stopped. Momentarily, when I came to, I looked to see if I had everything. I had my legs; I had my arms. I said, "It's over. I'm gone." That was what I did. I went over the freaking side.

From that explosion, it was funny. But later on, when the can picked us up, I was picking out little watch springs, like if you took a little old wristwatch and the watch springs? I was picking out little curly cues. I think what it was the brass combing from around the hatch or wherever it came from. It stuck all over me. I had a few shrapnel things in my leg. But anyway, that was the only damage I had done to me there. About a year later, I had a piece of metal come out of my knee.

INTERVIEWER: I assume you lost other people.

MR. ROCECK: Oh, sure. I think that was where the skipper, the executive officer and most of the officers got killed in that con. Naturally, that was your fire control system. I guess they killed a lot of guys on the gun.

INTERVIEWER: How many guys did escape?

MR. ROCECK: Well, totally, there were 41.

INTERVIEWER: There was that many? Out of how many men was that?

MR. ROCECK: Well, at that time, we had a complement between 85 and 90 that we used to carry.

INTERVIEWER: Over half the people were gone.

MR. ROCECK: Oh, sure. We had Pete Cabrunis . He was in the control room on the hydraulic manifold. George Brown told Pete Cabrunis, when he was going to scuttle the boat, to pull the vents. I don't know whether he got hung up trying to get out through the conning tower, where all that wreckage was. You couldn't go out to the after-battery hatch. They tried to get Chappel to get

off the *Sculpin* several patrols prior, but he refused to get off. He wanted to stay on the *Sculpin* as skipper. This one time, when we were operating out of Midway, we were having a leakage problem with that after-battery hatch. The skipper was afraid that the longer he hung around there, the more likely it was that they were going to get him off the boat. Finally, he said, "Weld that sucker shut," and they did. In order for Pete to get off, you would have had to go up to the forward torpedo room or all the way back to the forward engine room. But I still think he was probably trying to get through the conning tower.

INTERVIEWER: Well, he probably didn't know how much damage was up there.

MR. ROCECK: No. He probably didn't.

INTERVIEWER: Forty-one were in the water, in the boat.

MR. ROCECK: Actually, there were 42 of us. They picked up a couple of guys. One of them, they carried back to the fantail because he was wounded, and they threw him right over the side.

O'Rourke thought the Japanese were going to take him to the sick bay. He was all fouled up. When he saw what they did to him, he turned around and ran back up to the bow where they kept all of us on the bow.

INTERVIEWER: Wait a minute. Were the Japanese aboard the boat?

MR. ROCECK: No. The Japanese picked us up.

INTERVIEWER: They got you out of the water.

MR. ROCECK: Yes. At first, they were machine-gunning us in the water.

INTERVIEWER: Really?

MR. ROCECK: Yeah. Then, they got orders I guess to stop that. I have no idea how many they killed, if they did kill some of us. But there were 42 guys who were rescued. Like I said, one man was thrown over to the side.

INTERVIEWER: The Japanese were shooting at you.

MR. ROCECK: Yeah.

INTERVIEWER: Do you remember what the Japanese ship was?

MR. ROCECK: It was a destroyer.

INTERVIEWER: Do you remember the number or anything like that?

MR. ROCECK: No.

INTERVIEWER: What did they do, get you on the destroyer?

MR. ROCECK: Yes. They picked us up out of the water and took us into Truck Island. Then, they brought us in on Truck, put us in trucks, and took us to their military compound.

INTERVIEWER: Let's not jump ahead. What happened to the *Sculpin*?

MR. ROCECK: Well, when George Brown gave the orders to open the vents and scuttle the ship, the *Sculpin* made a normal dive. When I was in the water, I saw her go down, just making a normal dive. Then, while I was in the water, I heard the explosion. I felt the explosion. When the salt water hit those batteries, they just blew up. You could feel it in your spine. You were supposed to float. We didn't know that. You were supposed to float on your back, so any explosions in the water wouldn't affect your spine.

INTERVIEWER: I see.

MR. ROCECK: But they never told us that. Nobody knew anything about that.

INTERVIEWER: You didn't have any life preservers or anything around your waists?

MR. ROCECK: No.

INTERVIEWER: You could have drowned.

MR. ROCECK: Well, I was a good swimmer. I was a good swimmer. I played in a lot of water, so that helped me.

INTERVIEWER: Did the Japanese sailors, since you were on board their destroyer, treat you reasonably well?

MR. ROCECK: Oh, yeah. Well, they got orders, I guess, because they herded us all up on the top of the destroyer. Then, they put a tarpaulin over us and gave us a five-gallon tin of water. That was what we had. We stayed down there until the next day, when they came into port to Truck.

INTERVIEWER: But they treated you reasonably well, huh?

MR. ROCECK: Yes. They didn't harm us on there, no. The only thing, like I said, is they threw that one injured man over the fantails.

INTERVIEWER: I thought it was when you were leaving your boat that that happened.

MR. ROCECK: No. They were picking us up with the destroyer, and this one man was injured from a bullet.

INTERVIEWER: Do you know who he was?

MR. ROCECK: I think his name was Weed. I'm pretty sure.

INTERVIEWER: They threw him over the side, huh?

MR. ROCECK: Yeah. They carried him to the fantail, and they threw him over the side.

INTERVIEWER: Geez. That must have made you nervous.

MR. ROCECK: Rourke has since passed away, but he was our gunner's mate. He went with him. He thought they were going to take him to the sick bay to take care of his wounds, but they just threw him over the side. Well, when he saw that, he ran back up to the bow, where we were.

INTERVIEWER: Did you get some reasonable food and treatment at the brig?

MR. ROCECK: No. They give us each a rice ball. That was all right, because we were not hungry. We were in good shape, but we were thirsty. That was what we wanted. We just couldn't get

enough water. All they gave us was a shot glass full of water each. On Truck, they had wells. On the ship, they had to rely on rainwater for their water supply, so they were skimpy on fresh water.

INTERVIEWER: They had to do that even for themselves, probably.

MR. ROCECK: We had several men who were injured. We had one man with a hole in his palm about the size of a half dollar. We had another man that had his arm broken, I imagine, by a .50 caliber. We had another man who almost had his whole calf sliced off. George Brown was trying to get medical attention for these men. They got us in three cubbyholes. In one corner, each cubby hole, the hole in the floor, was your toilet. We had to take turns to let the injured men try to lay down. We gave them as much room as possible, and the rest of us stood up.

INTERVIEWER: There wasn't that much room to sit or lay down.

MR. ROCECK: No. There wasn't. They had three small cells like that split up for the enlisted men. You were squashed in there like sardines.

INTERVIEWER: It probably was hot, too.

MR. ROCECK: It was hot. You're darn right. Then, those wound were starting to smell, being gangrene. Finally, after about two or three days, there was a young officer who came over there. They were questioning us, too. They blindfolded you, and then they led you outside a compound. I could see a little portable desk there, and I guess they had a nip in the back of the desk. They had an interpreter, and then they had another Japanese. Then, this Japanese guy would talk in Japanese, and the interpreter would repeat what he said, in English. They wanted to know different information. If they didn't think that you spoke fast enough, then they would nod to this sailor, and the sailor would whack you with a bat. If he hit you across the spine, you'd just drop like a log.

INTERVIEWER: He didn't hit you on the butt. He just hit you in the back.

MR. ROCECK: Right.

INTERVIEWER: I understand they would have ten questions, nine for which they knew the answers. The tenth was what they really wanted to know.

MR. ROCECK: That I don't know.

INTERVIEWER: That was what the guys were telling me. Did you have to endure that beating?

MR. ROCECK: Well, we were there ten days. That one young Japanese officer told George Brown that he was trying to get him over to the younger side of the island.

INTERVIEWER: They sent a Japanese officer. Did that mean that he was trying to be the good guy and bad guy? Sometimes, they play that game.

MR. ROCECK: No. George Brown was trying to talk him about getting medical attention for the injured. We were on the old side. They weren't about to do anything. They took three men, finally. I think on about the third day, they took them to the hospital. I didn't see them again until we were going to be shipped on the aircraft carriers. The three wounded men were on the carrier that I was on.

INTERVIEWER: Do you know the carrier you were on?

MR. ROCECK: I was on the *Chuyo*. It was not a full-fledged carrier.

INTERVIEWER: Was it a baby flattop?

MR. ROCECK: Yes.

INTERVIEWER: How soon did they put you on the carrier after you were captured?

MR. ROCECK: Well, we were captured on the 19th of November. I think it was around the 2nd or 3rd of December that we were put on the *Chuyo*.

INTERVIEWER: Was that 1943?

MR. ROCECK: Yes.

INTERVIEWER: That was two years after the war started. You were out there for two solid years then.

MR. ROCECK: Yeah.

INTERVIEWER: They put you on a carrier.

MR. ROCECK: They split us up. They split us up and put 20 on one and 21 on another. I was on the one with twenty-one. The guy who had the broken arm had it amputated. They amputated this guy's hand. But they bandaged one guy's calf. They told me that they were doing the amputations without any anesthetic, and they were firing him questions about submarine service. I don't know why they didn't cut that guy's leg off. His calf was almost torn off.

INTERVIEWER: How long was it between the time you were captured and when they put you on the carrier?

MR. ROCECK: It was ten days.

INTERVIEWER: Is that all it was?

MR. ROCECK: Yeah.

INTERVIEWER: They ran you right out of there.

MR. ROCECK: Well, from what I understand, they got orders from Tokyo or Yokohama to ship us up to Japan. Of course, the Japanese navy had this secret camp, their interrogation camp, Ofuna. That was to what we were brought, that camp. While you were there, you were not registered as a Prisoner of War. You were only registered as a Prisoner of War after the Navy turned you over to the Army. Then, the Army registered you as a Prisoner of War. They could do anything they wanted to you at Ofuna, and nobody would know the difference. Most prisoners at that camp were either submarine or aviation men.

INTERVIEWER: That was in Japan.

MR. ROCECK: Yes.

INTERVIEWER: That was where you ended up.

MR. ROCECK: Right. We went on the convoy, and the seas were in typhoon-like conditions. We got hit. The USS *Sailfish* hit that carrier I was on.

INTERVIEWER: How long were you on board before you got torpedoed?

MR. ROCECK: I think it was maybe two, three days, or somewhere around there.

INTERVIEWER: The *Sailfish*, the old *Squalus*, hit you.

MR. ROCECK: Right.

INTERVIEWER: Of course, you didn't know that.

MR. ROCECK: No. We didn't know that, but we knew a submarine got it. They had us in a compartment I don't know how many flights below deck. It was several, because we were below the water line. The room was about this size here. In one corner, they had the head, and they had a bar, and you had to pump your refuse, against sea pressure, overboard. They had us locked in, and they had a guard posted. There again, when we asked for water, they just wouldn't give us the amount of water we wanted.

I estimate that it was around midnight that we got hit. Midnight is pretty close to what the *Sailfish* report reads, too. Those of us who were sitting on the deck, we flew up about two or three feet from the concussion. I think it was pretty close, underneath five compartments. Then we heard the damage control and all the hustle and bustle. You could hear them surveying the damage. It all got quiet, and about a half hour later, you'd hear all the bings, and then the slosh and bang, and you know it broke loose. Like I said, it was tight room condition. They got that damage repaired again, and it was quiet for a while. But then, after about another half hour, you could start hearing that stuff breaking up again. All the power went out, and we could smell smoke. Then, we felt

water seeping into our compartment. Of course, our guard, left. We tried to open the hatch, but he had it locked from the outside. What we did was take off that bar from the head. Then, we got as many guys as could push on one end of that door to where we could get that bar in an opening. Then, on the count of three, we pushed and heaved. On the second try, we did it. We popped the door off of that sucker. We broke the lock.

INTERVIEWER: It was a vertical, normal sea door.

MR. ROCECK: Right. But if it had been an American ship, we couldn't have done that, because our ships were built a lot stronger. But on those, it was flimsy. That was the way we broke out of that compartment. We had already made up a story. If the damage controller, or anybody, wanted to know how we got out, we were going to say, "Well, the damage controller let us out." But we saw all of them running past us. They didn't pay any attention to us; they had their hands full with their own problems.

We didn't all want to go wandering off, because it was dark. We didn't know where to go. Denny Moore asked anybody who had been on a carrier or surface ship to try to lead us out of there. There was one guy. I don't even know what his name was, but he started leading us up. We all held hands. We finally worked our way on up to just below the flight deck. We passed one compartment that had hundreds of life jackets in it, so we all went in there and put one on. Then, we passed another compartment. It looked like a galley or part of a galley system. They had these crates, which were full of bottles of soda. That was where we first got our fill of being thirsty. We drank the heck out of that soda.

Then, a Japanese officer came down, and he gave a bunch of orders. He made us form a line up on to the flight deck. They had these long pine logs lashed underneath the flight deck. We had to pass those on up, and the nips would tie those logs together. They were making rafts. When we

got all of them topside, they brought us topside and kept us in a circle on top of the flight deck. At one time, they had us tied. They tied about 12 of us together with a half-inch line, and then they ran out of rope.

The majority of the Japanese topside did not wear life jackets. Why they didn't just go down there and put one on, I don't know. Maybe they figured the carrier wouldn't get sunk. But the Japanese naval officers not only had on their life jackets; they had on their big, long coats and life jackets. Then, they had their Samurai swords canned in between. Those were family heirlooms to them, and they weren't about to part with those Samurai swords. But you wondered about all that added weight. There was one boat out on the water. To me, it looked like it was only about a 16-foot boat, and they had three high-ranking Japanese officers in there. There was no other method of floatation except these rafts that they were making on the deck.

One time, this Japanese officer came over to us and tried to tell us that there was help coming. He said that they had radioed in for help to come, and they were going to tow us into port. Anyway, that was the drip that we got. But just about the time it got clear and you could see a little bit on the horizon, we saw what looked like either a destroyer or a cruiser coming over toward us. That was when the *Sailfish*, again, pushed a couple more fish into the carrier.

While we were down below, we heard what I thought were internal explosions. It was actually fish that the *Sailfish* was throwing into the carrier. I was invited to a reunion in 1979, with the *Sailfish* and the *Squalus* crews, and Captain Ward, who was skipper then, told me, "What you thought were internal explosions were the fish we were firing into it."

INTERVIEWER: When they did it again, it was beginning to be daylight then.

MR. ROCECK: Yes. It was beginning to be daylight when we were topside.

INTERVIEWER: Was the storm still going?

MR. ROCECK: Yes. The storm, it was raging. The rages, man, they were monstrous waves. Apparently, when the *Sailfish* saw that destroyer or cruiser coming in sight, they figured they'd better send more fish in, which they did, and they got it right in the bow. You could see the big puff of smoke that came billowing up over the flight deck.

Denny Moore and I were hanging to a searchlight. They had one of those collapsible search lights on the flight deck, maybe about 25 feet off from the starboard side. Kerry had a slight list. Most of the Japanese, and then the *Sculpin* men, were all on the high side. Denny Moore and I were hanging on this searchlight.

INTERVIEWER: You were on the low side.

MR. ROCECK: Yeah. Well, it was on the same side, but we had a search light.

INTERVIEWER: You were on the high side then.

MR. ROCECK: Yes. We were still on the high side, but we were trying to call the *Sculpin* men to come over by the search light, to get away from the people in front and back because when you were going to go down, you had people in front of you, and you were going to have people piling on top of you. But they just stayed there. Denny and I just hung on to that search light there. When she hit the last time with those torpedoes, the moat started going down, and then she started going down. I don't know why, but about a hundred feet from the water, I turned to Denny. I said, "Let's go, Denny." I dropped. I slid down the pipe. Although I was a darn good swimmer, I was trying to break that suction. But I couldn't break, and I thought, "This is it," and I started sipping water. Then, I looked. I don't know if the suction subsided as she was going away from me or maybe a bubble blew me up closer to the surface. I had seen the light. I made one last attempt to break surface, and I did. When I did break surface, there in front of me, about ten or fifteen feet away was one of the rafts that they made. I swam for that and latched onto that thing. Meanwhile, these

gigantic waves were hitting me. I knew I couldn't hold on to that son of a gun too much longer, so I worked my hand and wrist to that lashing so that if one of those big waves threw me against the raft, it wouldn't tear me away. After about a half hour, I bet there were 28 men on that same raft with me.

INTERVIEWER: Were they all Japanese?

MR. ROCECK: No. We had one mess boy and one officer off the *Sculpin*.

INTERVIEWER: Who was the officer?

MR. ROCECK: I think his name was Smith.

INTERVIEWER: Do you remember the mess boy's name?

MR. ROCECK: No. I could if I had the roster.

INTERVIEWER: That's all right. Was George Brown on the other carrier?

MR. ROCECK: Yeah.

INTERVIEWER: Okay. That was to where George disappeared.

MR. ROCECK: Yeah.

INTERVIEWER: Just you three survived.

MR. ROCECK: Well, we didn't survive right then, because four or five hours later was when the destroyer decided to pick us up. She was afraid to pick us up. She was afraid the submarine was going to get her, so she just kept circling and pinging. Then, when she felt it was safe, she started going and picking up the survivors.

The only bad thing was that their method of picking us up involved a bunch of lines hanging over the side and one Jacob's ladder. Well, if you picked up that wet line, once she rolled, all your weight was out of the water and on that wet line, and you slid right back down. Your best method was to get to that ladder. Luck would have it that a wave pushed me toward that ladder. I

was still on the raft. I grabbed that ladder. Then, one of those Nip officers climbed on top of the ladder and walked over all of us to get to that sucker. When he stepped on me, he broke my grasp on it, and I went down. Well, then, I lucked out again. When I surfaced, another wave pushed me back up against that ladder. I didn't have the strength then, so I just threw my arm through one of the runs, and I latched on like that.

Well, before they took us on the carriers in the compound, they shaved all our hair off, and they gave us undressed navy blues to wear. Well, I looked like a freaking Nip in the water. All we had was a little rope and a square tag, and I guess our names and our serial numbers were inscribed on that wooden tank.

INTERVIEWER: Were these undressed Japanese navy blues?

MR. ROCECK: Undressed Japanese navy blues they gave us, yeah.

INTERVIEWER: Oh, okay. They took away your work uniforms.

MR. ROCECK: Right. They took all our regular Navy clothes while we were in Truck. They took all of that away from us.

INTERVIEWER: In the meantime, were you still wearing your life jacket?

MR. ROCECK: No. They took the life jackets away from us while we were on top of the carrier.

INTERVIEWER: They did?

MR. ROCECK: Yes. They took our life jackets away, and they gave them to the other Japanese sailors. Like I said, they could have walked one flight down, and there were hundreds in that compartment. I don't think they thought that that carrier would get sunk.

INTERVIEWER: You were hanging onto that ladder with your left arm through and holding on with your right arm.

MR. ROCECK: That's right. Then, they picked the ladder up and flanked me out on deck, face down, and dropped the ladder back down. I guess that I lay there for maybe about ten minutes, and somebody flipped me over. Well, soon, as they recognized that I was not Japanese, I went, "Yer, yer, yer, yo," and all that.

Then, I felt myself being picked up and carried to the fantail. I said, "Uh oh, they're going to throw me over the fantail, too." They got me to the fantail, and I guess they got different orders, because they brought me back up on mid ship and threw me in their little laundry compartment. They didn't tie me up. They didn't shut the door. They just threw me in there and left me.

When they took me back to the fantail, I saw the sailors topside with big, long bamboo poles, and they were going like this over the side of the ship. I don't know if they were trying to help them up or push them down, but heck, they lost a tremendous amount of their own men because they didn't have the proper means to get those men aboard. Now, had it been calm seas, it would have been all right, but not in those kinds of mountainous conditions. Man, when we were in the water on that raft, you could see that destroyer rolling. You'd see most of the builds ----, you know what I mean?

INTERVIEWER: Yeah, turning.

MR. ROCECK: Oh, man.

INTERVIEWER: You were in the laundry room.

MR. ROCECK: I was in the laundry room. I think I stayed there for maybe two or three hours. Then, I heard the turbines winding up. I guess they finally got what they could aboard, and they decided to leave the area. They wound up. They didn't put anybody else in there with me. I figured that if they got anybody else, maybe they took them to the fantail. Maybe they put them in the compartment down there, never realizing that I was the only guy.

INTERVIEWER: I assume the *Sailfish* took off after the last attack.

MR. ROCECK: I think they did. I think they got out of there, if I remember right and according to that report.

INTERVIEWER: I wanted to ask you earlier than this, but they bugged out. What happened to you in the laundry room?

MR. ROCECK: I stayed there all night. They still didn't tie me up; they didn't lock anything. The door was wide open. But what the heck could I do? I was cold. It was nighttime, and I was cold. They had a little tank in there that was filled with water. I put my hand in there, and boy, it was warm. It felt really warm. I crawled up and sat in that sucker all night long, and I stayed warm.

Then, the next day, I got out of there. I had a young Japanese sailor come in there. He was talking and then telling me that he was in the engine room. I told him the same thing. I motioned, and he understood. He came back about 15 minutes later and gave me a little hard cracker. He gave it to me. If he were ever caught doing that to me, they would have killed him.

I was having a problem eating it because I couldn't work up enough saliva. I took a little bite, and I bet I chewed for about ten or fifteen minutes, just to work enough saliva, but I finally got it all down. Then, I had the chief come in there. He was drinking saki, because I could smell it on him. He came in there and yak, yak, yak. Then, he slugged the heck out of me and left. About a half hour or 45 minutes later, he came back again and beat me again.

They pulled into port in the morning. When we pulled in, I was still free. I had seen everything. We tied up. I saw the whole harbor and the ships that they had. Some were badly damaged. Some were half sunk.

INTERVIEWER: Do you remember what port it was?

MR. ROCECK: I think it was Yokohama. Finally, that chief came in there. After we were tied up, he came in there with three or four men and about fifty feet of rope, and they tied me up so that I couldn't even move. Close to noontime, a chief came in there by himself. He picked me up, took all that line off, took the blindfold off, and he tied me at the wrists. He put a blindfold on me so that I could only look down. He was a big guy. Man, he was a big sucker.

Then, he took me out to the gangway. They had a pair of sandals. I put those on. He took me on the launch, and we rode on the launch for about ten or fifteen minutes. Then, we got to land, and I could hear the city's activity. He was taking me to the railroad station. He led me through the streets to the railroad station. I ripped the seat of my blues when I slid down that flight deck, so my rear end was hanging in plain view. First, I felt kind of self-conscious. Then, I said, "Heck, I don't give a damn. I've got more problems to worry about than my freaking rear end." He took me in the railroad station and sat me down. I guess we were there for maybe 15 or 20 minutes. I heard him talking to a gal. He was talking and talking. Finally, he lifted my blindfold. Well, the gal he was talking to, she was built like state side. She was a doll, God. She had on a nice, short skirt, with silk stockings and high-heeled shoes. Oh, she was pretty. I can understand why he was making points with her. Apparently, she wanted to know what an American looked like, and that was why he took that blindfold off. After a few minutes, he put it back on. She left. Then, we waited for a train, got on the train, and we rode several hours.

INTERVIEWER: In the meantime, you got no food or water.

MR. ROCECK: No, I got nothing.

INTERVIEWER: I don't know how you endured.

MR. ROCECK: When we got off the train, he started running me. I tried to explain to him that I couldn't run. He had those boots, and I had these things. He understood that, but he also went like

this. He wanted to get me there in time to eat. We made it in time. But he treated me all right.

There was no animosity there. When he got into Ofuna, there were two gentlemen there. Well, they weren't gentlemen, but they were dressed state side. Apparently, they were a Japanese company.

That was their secret police.

INTERVIEWER: They were the shirt and tie guys.

MR. ROCECK: Yeah. One of them asked me what ship I was off of. I told him I had just come off a Japanese aircraft carrier that was sunk. He replied, "Oh, no. I don't mean that. What American ship are you off of?" I told him, "I'm off the *Sculpin*."

INTERVIEWER: Was that okay to say?

MR. ROCECK: No. They were mad. They knew that the carrier was sunk.

INTERVIEWER: But was it okay for you to say that you were off the *Sculpin*?

MR. ROCECK: Oh, yeah. The other men were already there.

INTERVIEWER: Oh, I see. But you didn't know that.

MR. ROCECK: No. I didn't know that, no.

INTERVIEWER: I thought you were not supposed to say anything more than maybe an American serial number and all that.

MR. ROCECK: No. Denny Moore told us to make up a story and stick with it.

INTERVIEWER: By the way, Moore, the fellow who was hanging on the light with you, did you ever see him again?

MR. ROCECK: I don't know what happened. He never made it, so I have no idea if he followed me. Denny Moore was the chief of the boat. He was giving us orders and telling us what to do and what not to do.

INTERVIEWER: He was doing that when you were captured?

MR. ROCECK: Yes. Old Denny Moore was a rock of Gibraltar as far as that was concerned.

INTERVIEWER: You just played along with the Japanese.

MR. ROCECK: Yes. I made up a story about when I came in. They kept me in New London for a year. Then, they sent me to San Diego, and I stayed there for a year. Then, I went to Pearl Harbor and was working in the ship's service there. Then, they transferred me to the *Sculpin*. That was my first run. That was my story. Everybody made up his own story. If you stuck with it, you really didn't have much of a problem. In their navy, they didn't tell their people anything, either. They kept their people in the dark.

INTERVIEWER: Did you run into the rest of the *Sculpin* people who were on the other carrier, like George Brown, or were you by yourself for a while, when you first got to Japan?

MR. ROCECK: Oh, in Ofuna?

INTERVIEWER: Yes.

MR. ROCECK: We all had separate rooms, and you weren't supposed to talk, but we had ways.

INTERVIEWER: You did meet the other guys.

MR. ROCECK: Oh, yeah.

INTERVIEWER: You didn't feel alone.

MR. ROCECK: Yeah. That was on a Saturday. That was bath day. I got a bath. When I got in that warm water, I almost fell asleep in the darn thing, it was so relaxing to me. They gave me clothes to put on. They put me in one of them rooms, and I got a piece of fish. I got to eat something, anyway. Then, to the guys next to me and around me, I started telling what occurred to the carrier.

INTERVIEWER: You were a prisoner for two years, then, weren't you?

MR. ROCECK: Yes. I stayed in Ofuna, I think, for about three or four months. I was one of the first groups to be transferred from there, and then they took us to Eschu, in the compromise.

Eventually, little by little, the rest of the *Sculpin* men were transferred up there.

INTERVIEWER: The other twenty were transferred with you?

MR. ROCECK: Yeah.

INTERVIEWER: I just saw a guy going up the stairway. He was wearing a *Sculpin* vest. I don't know who it is. How many, out of the twenty, are still with us?

MR. ROCECK: I think there are nine of us left now, and there are some that we don't know. I had another shipmate, Wyatt Earp, who was on there as long as I was, way before the war. He made it all the way through, just like I did. But we don't know what happened to him. We have no idea.

Now, some of them, we do know about. They've passed away.

INTERVIEWER: What did you do in a copper mine?

MR. ROCECK: Well, in a copper mine, I started out as a mucker. In other words, you had a metal tray about that big with two handles. You had like a triangular hole. You filled up this rock and put in a car. A car was maybe about that long, about that wide, and about that deep. You had to fill eight of them a day per man. I worked for about a year doing that, and then they made a driller out of me. Cooper was a driller, too. Ed Keller was a driller. They're here. They were in prison camp with me. But we screwed them as best we could. The drilling guns were all air operated. The miner labs you had those carbide stones, and you'd drip water. It would form a gas. Then, you had a little reflector, which was your light in the mine. Well, when the carbide stones would dissipate, they were like fine talc. We would take that talc and put it in the air supply, the air drill. Then, we'd put that air hose back on. The drill would work fine for maybe two or three days, and then it would gum up.

INTERVIEWER: I kept thinking it was an open pit mine.

MR. ROCECK: No. It was all enclosed.

INTERVIEWER: That was another claustrophobic job.

MR. ROCECK: Well, there was that. They also had a lot of those earthquake tremors over in Japan.

Boy, those scared the heck out of you, too. You were inside, and you felt that thing shake. You had to be careful of the overhead because sometimes that rock would fall. One time, five or six of us were in a group, taking a break. Then, as soon as we felt little particles of sand dropping, we all scattered because we knew something was going to happen; we didn't know what. We all got away, except one man, who was an Army boy. It broke his darn leg. A big chunk of rock fell.

INTERVIEWER: I don't like to jump too far ahead, but I better be sure to do it and get it in. How did the war end for you?

MR. ROCECK: Well, the first sign we saw was the fighter planes, our fighter planes.

INTERVIEWER: You should have seen bombers before that.

MR. ROCECK: No. Everything was south of us.

INTERVIEWER: What part of Japan were you in?

MR. ROCECK: I was in the northern part, north of Yokohama.

INTERVIEWER: Oh, okay.

MR. ROCECK: George Brown was, I think, closer to the cities, but we were up in the mountain area. We didn't even hear bombing or anything. We were too far north.

INTERVIEWER: There were no rumors, no nothing?

MR. ROCECK: The only information we got came to us once in a while from some of those Korean workers who had relatives down in the city. Once in a while, they would go down there to

visit. They would come back, and they would give some of the guys information about the bombing and how bad it was down there. That was the only news we had as far as that goes. We did have a chance to get some news periodically from the mine office. The nightshift crew that went to work passed the mine office. Every once in a while, it would happen where there would be nobody in that mine office. The last guy would dart in there and grab a paper if there was one available and bring that paper back.

INTERVIEWER: It was in Japanese, though.

MR. ROCECK: Yeah. But it had the truth in it because that paper was for the educated people. They had other newspapers for the common people.

INTERVIEWER: Was it in English?

MR. ROCECK: Oh, no. It was all in Japanese.

INTERVIEWER: How could you read the paper?

MR. ROCECK: We had one guy who was an interpreter, an Australian. He could read it, and he could speak it.

INTERVIEWER: You said that you started seeing the Navy fighters coming in.

MR. ROCECK: Right. Some of them dropped some candy and cartons of cigarettes. What they were doing was lining up to where these prison camps were. Then, I'd say about five days later, one of the big bombers came over, and he dropped a pallet of food for us. He dropped it just about a hundred feet in front of the entrance of the camp. He made a couple of runs, and he got it squared away and dropped that sucker. The only problem was that the chutes didn't have a chance to open up fully, and it really buried itself in the ground. We went out there.

INTERVIEWER: What happened to the Japanese guards that you had? Did they dig out?

MR. ROCECK: Oh, no. They were still there. When the American fighter planes came over, that Japanese commander said that the war was over and that Japan was dictating the peace. They still didn't want to admit that they were beaten. That was the way they were. In fact, the people in the mine, they felt, or were told, that Japan was bombing San Francisco, New York, Chicago, and they believed that. But that was the way the Japanese were.

INTERVIEWER: Well, we were propagandized tremendously at our end, also. It worked that way on both sides.

MR. ROCECK: Absolutely.

INTERVIEWER: Eventually, you saw some American troops, later, in August?

MR. ROCECK: They said the Red Cross was going to come there, but no, they never did show up. The next thing we knew, they took us into the railroad station.

INTERVIEWER: The Japanese took you there?

MR. ROCECK: Yes. They had the secret police, the company, posted from the camp all the way into the railroad station. The reason we found out was that they were afraid that the people would retaliate and do harm to us. They were afraid that they would be held responsible if we got harmed. You didn't see one person, not even a dog, nothing. It was like a ghost town. You didn't see anybody looking out the window. That was how deadly afraid they were, the secret police. Then, we walked out through the town and got on a train, and they brought us into Yokohama.

INTERVIEWER: Did the Navy meet you then?

MR. ROCECK: Yes. Well, the Navy didn't meet us. The first ones I saw were two Army nurses. When that train door opened up, there were these two beautiful Army nurses in full uniform. They had two trays, and they had cigarettes and candy bars out there.

INTERVIEWER: How much did you weigh?

MR. ROCECK: We averaged around ninety pounds each.

INTERVIEWER: How much did you weigh when you were on the *Sculpin*?

MR. ROCECK: Oh, I weighed about 180.

INTERVIEWER: You lost almost ninety pounds.

MR. ROCECK: Oh, absolutely. We were nothing but skin and bones.

INTERVIEWER: Will you eat Japanese food now?

MR. ROCECK: Oh, yes. I didn't eat rice for years. I refused to eat it.

INTERVIEWER: Do you have any animosity to the Japanese now?

MR. ROCECK: Not now, no. I wouldn't have anything to do with them.

INTERVIEWER: Do you ever have any nightmares still?

MR. ROCECK: I have nightmares to this day. In fact, I had one a couple nights ago. I just flail and fight. Sometimes, I talk.

INTERVIEWER: It must drive your wife crazy.

MR. ROCECK: Well, I don't have a wife anymore. Both of my wives passed away. I could never have anything around my head like pictures or anything because I go nuts when I have those dreams.

INTERVIEWER: I wonder if your former wives had problems with you that way?

MR. ROCECK: Well, yeah. When I was sleeping, they sure did. But all she had to do was holler out my name. That was what I told the guys, when I'm with my shipmates, to just holler out my name, and I'll snap out of it.

INTERVIEWER: George, where do you live?

MR. ROCECK: I live in St. Pete, Florida.

INTERVIEWER: Thank you. Do you think we pretty well covered everything? It seems like it. I don't want to beat this in the ground. Has the Naval Institute or anybody else ever interviewed you like this before?

MR. ROCECK: No. The only time we had an interview was when George Brown and I were talking with that skipper. I can't think of his name. Grand Adier .

INTERVIEWER: Grand Adier is his name?

MR. ROCECK: *Grand Adier* is the name of the submarine. God, I can't think of his name. He went through some bad times, too. They tortured him, that skipper. They really tortured him badly.

INTERVIEWER: Well, the feeling I get from just being up here with you guys for the last five or six hours is that you all went through hell together, and you're still friends. You're still shipmates. I wonder if there's still that quality of men around nowadays.

MR. ROCECK: That's a good question. More or less, I don't think there is because we were brought up under different circumstances.

INTERVIEWER: Like the Depression years.

MR. ROCECK: Absolutely. We grew to appreciate the smallest things, whereas the modern generation has a tendency to take a lot of it for granted. My gosh. Aboard the boats, you could throw your wallet on your bunk. You didn't worry about anybody stealing it. But I noticed after the war, things start changing, even on submarines.

INTERVIEWER: What happened to you after the war?

MR. ROCECK: After the war, I stayed in the Navy. I made a career out of it.

INTERVIEWER: How many years?

MR. ROCECK: I was in for twenty-two years. I retired in Jacksonville, Florida. I went back up to Illinois, and I stayed there until about five years ago.

INTERVIEWER: What did you do when you got out of the Navy?

MR. ROCECK: When I got out of the Navy, I worked at various factories. I finally wound up working for International Harvester. I put in 17 years there.

INTERVIEWER: Were you a mechanic?

MR. ROCECK: Yeah.

INTERVIEWER: You weren't on the production line or anything.

MR. ROCECK: No.

INTERVIEWER: You retired from International then.

MR. ROCECK: I retired from International, right.

INTERVIEWER: You're getting retirement money from the Navy and from International Harvester?

MR. ROCECK: Right.

INTERVIEWER: Why not?

MR. ROCECK: Yeah.

INTERVIEWER: Well, I think we've pretty well covered everything. I just want to thank you very, very much. To me, it's an honor to meet you guys. Personally, I want to thank you because you've been through so much, even more than some of the other guys. You got sunk twice.

MR. ROCECK: Well, yeah. Like I say, I think that man up there is watching over me.

**UNDERSEA & HYPERBARIC MEDICAL SOCIETY**

**Interview  
of  
ADMIRAL GEORGE WORTHINGTON**

Friday, April 23, 2004

## PROCEEDINGS

INTERVIEWER: The date is Friday the 23rd of April, 2004, and this is Dick Vann. I am interviewing Admiral George Worthington. George, this shouldn't take too long, I think. I guess what I'd like to do is just summarize what was in your pre-interview letter, which will be pretty brief. You can comment on it as need be as we go along. Then, I've got a few questions afterward.

ADM WORTHINGTON: Go ahead.

INTERVIEWER: In 1979, you were at OP37, and you worked for Jim Barnes and Ted Lyon after that. The DDS was there. That was managed by Ray Smith and later on by Tim Holden. The basic effort was to keep the funding alive.

ADM WORTHINGTON: That was it. We also sought to gain acceptance from the submarine community.

INTERVIEWER: Yes. But it sounded like sort of a miserable time.

ADM WORTHINGTON: Oh, it was a great time.

INTERVIEWER: Oh. Getting money was difficult.

ADM WORTHINGTON: It always is.

INTERVIEWER: Yeah. That was the kneepad time. In 1982, you moved up to OP954, and that was when the Naval Special Warfare master plan was put together.

ADM WORTHINGTON: That's right.

INTERVIEWER: It was basically a wish list with goals and objectives.

ADM WORTHINGTON: Right. A lot of people said it was simplistic. I, of course, looked at it as the Magna Carta of my naval career.

INTERVIEWER: Indeed, and it turned out to justify the palms thereon in the future. It was a very important document.

ADM WORTHINGTON: It helped. People who didn't have master plans burned with envy.

INTERVIEWER: Yes. Where did the idea of the master plan come from?

ADM WORTHINGTON: That was in OP095. Vice Admiral Kenard McKee set that off a submarine. The CNO set him up as sort of the honest broker between all the warfare groups. For example, some sonars could be used by ships and airplanes. While each union was developing its own, the CNO at the time wanted to see if there was some way we could have economies across the board looking at how we fought. McKee's outfit came up. I think one of the first master plans accomplished was the anti-submarine warfare master plan. I think it was his brainchild that the various unions within the service, like the Airedales, the aviation, the submariners, the war fighting communities, should draft master plans of what they thought their requirements were, and then they would go look at them and see if there were any continuities between them. Do you understand what I'm saying?

INTERVIEWER: Yes. The idea was to get coordination between the different groups in the services.

ADM WORTHINGTON: We call it 'unions' in the Navy, though, the aviation, submarines, and the surface.

INTERVIEWER: Right. But you used it well beyond that. You used it to justify everything you wanted.

ADM WORTHINGTON: Oh, I think that was what they did, as well. We were kind of unique. We were not going to take the huge surface ship sonar and use it on an SDV, for example. The idea of the master plan was just to sit down as a war fighting community and put on paper where you think your direction ought to be. That was it. That came out of Admiral McKee's office. I don't know the exact person who did it. But I think somebody in anti-submarine warfare came up with it,

and they did a master plan. The rubric, if you will, was there. I said, "Okay, it was my idea to do one from the naval surface warfare."

INTERVIEWER: Oh, okay.

ADM WORTHINGTON: I can assure you there was a great deal of resistance from within the field community.

INTERVIEWER: Because it had something to do with paperwork?

ADM WORTHINGTON: They would usually get all their stuff on the back envelopes, and they would rob Peter to pay Paul. They'd never want to stand up and let anybody know what they were really doing. This was, 'Well, we can't tell them that and blah, blah, blah.'

INTERVIEWER: I see.

ADM WORTHINGTON: I remember one time in 1979, the requirements for radios were written on the back of an envelope, literally.

INTERVIEWER: I can believe that. Well, at that time, 1980 to 1982, Maynard Juarez was in OP37, and he was trying to get the Draeger approved for the teams.

ADM WORTHINGTON: The teams came in with complaints. I think that even Ted Lyon on the east coast came in with complaints about the Emersons, because they weren't being repaired properly. The maintenance of them was difficult. People said it was time to get a new closed-circuit breathing apparatus. Maynard was down there, and he got the challenge to do that. He did a study and got about four or five representative closed-circuit rigs from around the world, like the Pirelli. The English had a model; the Germans had one. They tested them down at Panama City. The director of diving got involved with it. It was the supervisor of diving, I guess, at NAVSEA.

INTERVIEWER: Would the Draeger or a closed-circuit oxygen have been in the master plan? I guess not, because that's kind of generic.

ADM WORTHINGTON: They started that before the master plan was published.

INTERVIEWER: Fair enough.

ADM WORTHINGTON: I went up summer '80 to OP95. It was later that year that the Draeger issue happened. I have to really sit down and use the calendar. But Maynard Juarez could tell you exactly. He's back here in D.C.

ADM WORTHINGTON: Where are you located?

INTERVIEWER: I'm in North Carolina. From 1982 to 1985, you were in OP37?

ADM WORTHINGTON: Yes. Then, I went up to OP95 for two years and the detailer called me and wanted me to go down and relieve Maynard. Of course, I had just gotten married and had a brand-new kid at that time, so I was delighted. Then, I went down there and became the program sponsor. The money and the master plan followed me.

INTERVIEWER: Okay, good. You used the master plan to great effect.

ADM WORTHINGTON: I think so.

INTERVIEWER: You used it to get lots of good, new stuff. Now, things were going pretty darn well, and then along came Grenada.

ADM WORTHINGTON: That was sort of a parallel effort. SUPIN6 went down and needed some stuff. They came in with the after action report, which got the attention of the CNO. He said to do it. I think it was some five million dollars involved in getting communications gear for SUPIN6, who was Bob Gormley at the time. They came up with that money by delaying the procurement of a radar for one of the new construction destroyers. They took the money and gave it to us.

INTERVIEWER: That must have made a lot of people happy.

ADM WORTHINGTON: In a matter of months, they got it back.

INTERVIEWER: Then, there was the Thayer memorandum and the SOF revitalization. Then, things began to happen. SOLIC and SOCOM came along as a result of the various external events.

ADM WORTHINGTON: That's right.

INTERVIEWER: Your big efforts within the programmatic realm, and you were commodore of group one from 1985 to 1987. You had some influence on the ASD DV in the palm in 1986 or 1987.

ADM WORTHINGTON: Right.

INTERVIEWER: Just sort out a couple of things for me. OP37, exactly how did that fit in? What was its role?

ADM WORTHINGTON: At the time, OP37 worked for OP03, and it was the amphibious warfare division. I had worked for two admirals there. My shop was called 371, which came out to be a stand alone. I got some reserves in there once in a while. But basically, it was a one-man shop.

INTERVIEWER: That was basically SPECWAR underneath?

ADM WORTHINGTON: The amphibs.

INTERVIEWER: OP37, yes?

ADM WORTHINGTON: Yes.

INTERVIEWER: Then OP954?

ADM WORTHINGTON: That was the amphibious strike warfare section, which was under 095.

INTERVIEWER: Oh, okay.

ADM WORTHINGTON: That was headed up by the naval aviators - rear admirals.

INTERVIEWER: Now what was the relationship of the earlier plans, 3801 and 3802, to what you were doing?

ADM WORTHINGTON: As I recall, those were plans that were done at NAVSEA for weapons, and they cited and were good. They were cited. They were letters. Instead of big ORs, they were just letter requirements for SEALs. They were diving gear, letters, and weapons, the stuff that you used in the water and stuff like that.

ADM WORTHINGTON: My master plan was to subsume them.

INTERVIEWER: Yes. Give me a perspective on the relationship that you had with the supervisor of diving and the supervisor of salvage.

ADM WORTHINGTON: Diving and salvage were the captains. We had good relationships with them. They were responsible for all of the diving equipment and had to make sure that stuff was certified, like the diving gear, the Draeger.

ADM WORTHINGTON: We had a working relationship with them because their authorities were spelled out. To get our stuff, we had to get approval from them. It was not a problem.

INTERVIEWER: Basically, it was just approval on equipment and procedures for diving.

ADM WORTHINGTON: We tried to use them as required, especially the dry deck shelter. It had to be fore-certified, which is a term that resulted from the USS *Thresher* accident. There was a company mate of mine from the Naval Academy, John Grafton, who was killed on that. I had a working relationship with them.

INTERVIEWER: That's pretty much all I have regarding questions, follow-up from your long e-mail. Is there anything else?

ADM WORTHINGTON: Just give me the opportunity to blow the whistle, as O'Reilly says.

The diving gear was the open-circuit and the closed-circuit. They don't use too semi-closed too much any more, the SDVs, the dry deck shelters, and the ASDS. I recall doing some documentation on the advanced systems, saying that we needed a dry system. I can't remember if

that was called out in the first master plan or later. The idea was to make the advanced seal delivery system like a dry deck shelter that flew away and left a clean submarine.

INTERVIEWER: Yes.

ADM WORTHINGTON: That's what we have today.

INTERVIEWER: Yes. Okay, I think that pretty well covers it then.

ADM WORTHINGTON: Call Maynard on the Draeger stuff.

INTERVIEWER: Well, thanks very much, George, and I'll send this stuff in to UHMS and see where it goes.

ADM WORTHINGTON: If you would go to the records, you might be able to get a copy of those. I think there were two master plans. Obviously, they could be declassified today. I think they were secret at the time, secret from us as much as the enemy.

INTERVIEWER: Yes.

ADM WORTHINGTON: Then, Noel Cooke , who you recall I mentioned was one of the original architects of the RESOF revitalization, is alive and well.

INTERVIEWER: Well, I appreciate your input on this and I will pass it along.

ADM WORTHINGTON: Okay, Dick, thanks.

INTERVIEWER: Thanks a lot.

**Let me add as a postscript here that there is a rather long e-mail that should go with this tape, and Don Chandler already has it. I will send up another copy as well as a hard copy with this particular tape.**

(Whereupon, the INTERVIEW was concluded.)

\* \* \* \* \*

Dick:

Would be delighted to speak with you next week. May not require 2/3 hours...hopefully. You could probably stash my diving knowledge in a thimble in spite of previous qualifications in open circuit, closed and semi-closed SCUBA (Emerson/*Draeger* and MK VI), several submarine lock-outs (underway and bottomed), DDS lock-out (underway off Hawaii), a couple of SDV passenger rides (sucked!).... Programmatically, here's a brief "diving summary" from my positions in the Pentagon: three tours with OPNAV (OPs 37 and 954) and SECDEF (SO-LIC, Irish's old job, too).

1979, OP-37, working for Jim Barnes and later Ted Lyons. No significant diving involvement excepting the ongoing NAVSEA effort on the Dry Deck Shelter (DDS) program, managed at that time by Ray Smith, later Tim Holden. Effort was to ensure sufficient funding to keep the program alive and submariners interested. They weren't. Didn't want extraneous gear hanging off their ships. Main SSN effort was anti-submarine warfare against Soviet threat, plus the Boomers. The Los Angeles Class was gaining more prominence.

1980-1982, OP-954, sponsored a "Naval Special Warfare Master Plan," which was subsequently signed out by Lee Baggett in 1982 (fall). This document was essentially a "wish list" set out in a "goals and objectives" format. OK, it had some supporting arguments, etc. You can probably find a copy of this publication somewhere. It got great mileage during POM deliberations, to wit: I would fashion budget submissions based on the NSWMP objectives, typing the "NARM Data Entry Sheet," a computer-based form the budget guys would use to input line items into the prospective (proposed) Program Objective Memorandum, i.e., "POM." One of the objectives was mobility. In this we treated the need for better SDVs, and if I recall—although it may have developed sometime later on—we cited a need for a dry SDV, the Advanced SEAL Delivery Vehicle (ASDV). If ASDV didn't appear in the first Master Plan, it made its entry in POM documents very soon after as one of our RDT&E lines. I do remember supporting it from my spot as Group ONE commodore, 1985-87.

1982-1985, I moved downstairs back to OP-37 as a stand-alone shop, OP-371. Let me back up; whilst I was "upstairs" in "954," Maynard Weyers was in OP-37 fighting to get the *Draeger* (German) system introduced in the Navy. They did a lot of testing among available worldwide closed-circuit gear, U.K. and Italian, among others, and located on the *Draeger*. The NAVSEA certification people weren't particularly helpful, as I recall, although this may be unfair, I'll admit. The Supervisor of Diving help his turf very closely. But if SEALs have any alluring traits, persistency is one of them. We won....

During my OP-371 tour, I was extremely lucky to have the Master Plan, which followed me "downstairs." I was a fairly simple task to organize a POM submission based on it. The Master Plan objectives had all been vetted through the two fleets and SpecWar Groups, and signed out by a Deputy Chief of Naval Operations. It was a hard document for our OP-03 budgeteers to argue against. "Ah, gees, guys, CNO said do it,

and you don't want to fund it.... Let's go talk to Admiral Trost." That usually got their attention. Another thing happened in the spring of 1983, which was also helpful.

You may recall we had a couple of war like events take place during the early eighties. One was the Grenada operation, from which SEAL Team SIX emerged with a bunch of requirements that got CNO's personal attention. The Congress was beginning to get energized, too, owing to the sub-rosa efforts of a civilian staffer named Lynn Rylander, RIP. Lynn came to my office in, March, I think, and asked how SEALs did in POM 85. I said fine owing to the Master Plan: we had gotten out-year approval for another SEAL Team (EIGHT), *inter alia*. Lynn said he (they, the SECDEF guys) were going to fix the SOF problem in POM 85. One year, I asked? Yes, he replied. Well, I had had by then four years watching POM and budget execution crap, so I told him it would be impossible for the services to execute a one-year budgetary pump-up. Why?: none would be able to spend the money. The labs were already ceilinged out, that is engineers and scientists were already assigned to programs, and the labs couldn't hire more. Furthermore, all the people involved outside of SOF would have to have a learning curve to understand what we needed, etc. Also, the salient fact that we procured things in such small numbers, the budget impact wouldn't get anybody's attention. For all these reasons and more, I explained to Rylander that he needed to take a piece of paper, line out five years on one axis, monies on the other.... This way, he would be able to demonstrate budget and spending ramps that would be acceptable to the "green eye shade" guys and have a decent chance of being accepted by the services. If the services felt they could continue to push something out, they would feel more comfortable with the effort; most of the principles would be reassigned by the time out-years came to roost.... You know, someone else's problem, the old switch the chair routine.

So, on 3 October 1983, the Deputy Secretary of Defense, Paul Thayer, signed out the SOF revitalization memorandum addressed to all the services and the joint staff dictating that SOF revitalization would commence with POM 86 and be completed by POM 90. Fine, it's still going on, and you probably know the rest. Congress finally got involved, SOLIC and SOCOM got stood up, etc. The rest is history, as they say.

The Naval Special Warfare Master Plan and the Thayer Memo were hard documents to argue against. I might add, too, that before the 3 October memo was released, I had occasion to brief Noel Koch, Principal Deputy SECDEF for International Affairs (under Rich Armitage) and brief the Master Plan in the JCS tank. Koch wanted all services to have a SOF Master Plan. Anyway, armed with Thayer's memo and our NSWMP, POM deliberations were a walk in the sun...and a lot of fun. Winning is always better than getting it broke off in your ass. I remember the late seventies drills, running from office to office with knee pads begging for a dime....

Diving gear was certainly discussed in the Master Plan. Again, can't remember the ASDV in it but do remember starting the program later on in POM 86 or 87, as an out-year R&D effort. I may have caused it when I was NSW Command guy, sometime in the budget events or 1989-90. Chuck LeMoyné reminded me when he became the SOCOM budget guy that the preponderance of SOCOM fiscal impacts were Naval Special

Warfare programs—boats, SDV upgrades, AND ASDV. It was during this time, to conserve money, that I cancelled the SDV MK IX program (the two-man SDV) using the argument that the job could be done by the MK VIII SDV (and as an aside, that the MK VIII could carry Army guys, too!). I saved a bunch of dough! Millions in upgrade monies.

It is interesting to review a little of post-Cold War history, too. When the Soviet Union “went away,” we got more submarine services than we had ever enjoyed before. SUBLANT was all over us. SUBPAC, the same. They were both looking for new missions, their anti-sub task abated. (The B-52 Air Force guys were also looking for work, wanting to fly their bombers at 500 feet on SOF insertions....) They were halcyon days for Naval Special Warfare. And I would opine they have continued: ran the SOF war in Afghanistan, did well in Iraq (continue to), have two three-star admirals, are finally looked on with respect by the other Navy “unions” (Airedales and Bubble Heads), and SOCOM is, today, a “supported” command in the war on terror.

I might add another very important policy turn that occurred in 1983. Irish came up with the idea that it was time to move all the frogmen and SEALs into similar units, eliminate the UDTs and make them all SEAL Teams. This was momentous. I recall up in my OP-954 days explaining to my admiral the difference in UDT and SEAL missions, that one ended at the waterline, the other continued inland. He didn’t know the difference between IUD and UDT! So, the recommendation to merge into one naval commando unit was received with total commitment by all the assembled commanders at that particular “Cross Tell Conference.” I said, as sponsor, I would need letters from both fleets concurring with (and recommending) the “name change.” This last is important. Changing the name of a command is one thing; but we were actually changing the mission(s). Name changes are simple; changing missions is another, and we didn’t want to find out how hard it might be. For example, OK get rid of UDTs, change their name to SEAL—but there were equipment implications, as well. SEAL Teams require more stuff than UDTs. Without putting too fine a point on the effort, I got the fleet letters which were specific enough to enable me to get it done. I think the fleet commanders recognized there would be equipment implications, they’re not dumb. I just didn’t want to have to make all the rounds required to stand up a “new” entity. You have to place 30-day notices to Congress to ascertain any political ramifications, etc. Happily, it all worked out faster than I ever imagined. You know, “Sure, guys, come on in with your letters...” never thinking I’d see them before the Second Coming. It was all Flynn’s idea and it’s paid off handsomely over the years. In fact, I’m not sure the NSW community could have survived much less competed with Army and Air Force had we stayed so fragmented. It was hard explaining our “Blue” mission versus our “Purple” employment.

I know I’ve taken too long, here, so I’ll sign off for the moment. I look forward to hearing from you next week. I’m at (619) 216-1009.

Cheers,

George

**INTERVIEW OF  
GERALD McLEES**

Portsmouth, New Hampshire  
Saturday, September 27, 2003

## PROCEEDINGS

INTERVIEWER: I am at the home of Gerald McLees in Portsmouth, New Hampshire. First, thanks for inviting me to come in to give the interview.

MR. McLEES: I appreciate you folks coming, yes.

MR. KNUCKES: Can we get started, Matthew? Do you mind if I call you Matt?

MR. McLEES: No. That's what I go by now. I don't think half the people around here know my first name, even.

INTERVIEWER: Basically, what I'd like to do is to get your story. Let's start from the very beginning. Where you were born? What was your childhood like and how did you become interested in being in the Navy?

MR. McLEES: Well, I was born in Richmond, Kansas in 1914. My folks had a farm there and of course, I was a farm boy and went to high school and graduated. We lived about, oh, six and three quarter miles from Richmond. My transportation to high school was a horse. I rode a horse morning and night, to and from high school.

I graduated in 1938, I guess it was, from high school. I got out of high school. Times were really rough then. There was no work or anything, so this friend of mine with whom I ran around said, "Why don't we go out and join the Navy?" Without even telling my folks or anything, we hitchhiked up to Topeka, Kansas. I think we had about fifty cents in our pockets. When we got up to Topeka, the chief at the recruiting station was just about ready to go home, but we talked him into giving us the pre-examination and everything. I zoomed right through it, but my friend's eyes were bad. He kind of flunked out right away.

INTERVIEWER: You were 18 at the time?

MR. McLEES: Well, yes, I was 18.

INTERVIEWER: We can really relate to that; our son just turned 18. I can't imagine him going off on his own.

MR. McLEES: Well, after we came back, my folks were just happy that we did come back. About a month later, I got a call to go to Kansas City for my final exam, and I went. That evening, I was on a train for San Diego.

INTERVIEWER: Why did you decide on the Navy? Kansas doesn't have a whole lot of water.

MR. McLEES: It didn't make much difference. That was the first recruiting station we came to. I didn't know one from the other, the Marines or the Army. The kid that I went with was kind of in favor of the Navy, too. That was one reason. As far as I was concerned, I didn't know one from the other.

INTERVIEWER: Was war imminent at that point?

MR. McLEES: Not that I know of, no.

INTERVIEWER: It was primarily just to get on your own, then.

MR. McLEES: Yes, it was something to do. I think it was in August of 1934 that I left Kansas and headed for San Diego. That was when I joined the Navy.

INTERVIEWER: I just got back from San Diego the day before yesterday, as a matter of fact.

MR. McLEES: Is that right? I haven't back there since, actually, I came out of the recruiting station. After three months of sitting in the recruiting station we were put in the transfer unit, which was waiting for orders from someplace. One day, we came in from our work detail and found quite a group of names on the bulletin board, including mine, of guys who were being transferred to Pearl Harbor. We were running around like crazy, trying to find out where in the heck Pearl Harbor was. In those days, nobody had ever heard of Pearl Harbor. We found out. We got on a transport, and that was why I ended up at Pearl Harbor.

INTERVIEWER: Pearl Harbor is a long way from Kansas.

MR. McLEES: Of course, being just a boot, they put lot of us right on mess cooking. One day, I got acquainted with one of the guys who was mess cooking with me and he was on a submarine there, an S-30 boat. He said, "Why don't you come down in the boat? The chief is looking for another seaman." After we got our work done there, I went down. That evening, I had a .45 strapped on me and was on topside watch, on the submarine.

INTERVIEWER: Were you then officially assigned to the S-30?

MR. McLEES: Yes, I was assigned to the S-30 boat.

INTERVIEWER: Today, submarine duty is strictly a volunteer service.

MR. McLEES: That's right.

INTERVIEWER: Was it voluntary then?

MR. McLEES: Yes, I guess it was voluntary then. Normally, most everybody was going to New London to submarine school. I always said my folks couldn't afford the tuition and that was why I didn't go to submarine school. In 1938, the S-30 came back to New London.

INTERVIEWER: The S-boats were relatively small, I guess.

MR. McLEES: Yes. We only had a crew of about of probably forty or fifty men.

INTERVIEWER: The typical daily operation would be what? Would you go out?

MR. McLEES: We just went out from the submarine base in Pearl Harbor. We would go over maybe to Lahaina Roads for gunnery practice maybe once a year, and anchor off of Lahaina. Lahaina was nothing in those days. Now, it's a big tourist center.

INTERVIEWER: You were on the surface most of the time?

MR. McLEES: Yes. The diving was for short periods of time. It was not like it is today, where they go down and stay underwater for days at a time.

INTERVIEWER: Can you talk a little bit about the features were on the S-30 boats, as far as the human comforts or lack thereof?

MR. McLEES: Actually, it wasn't too comfortable. We had no air conditioning in those days. Everything was kind of crowded.

INTERVIEWER: Were there sleeping facilities?

MR. McLEES: Yes, we had sleepers, but I think our bunks were four-tier high.

INTERVIEWER: I'm trying to think of the submarine that sank off of Honolulu. It was an F-boat.

MR. McLEES: It probably was, yes. I think one sank off here, the S-52.

INTERVIEWER: Was that the S-51?

MR. McLEES: It was the S- 51 or something like that, I think. The S-4 sank off of Rhode Island or someplace out there, because I know that while I was in Pearl, they toted it out there and sank it. They used it as a target ship. It was sunk off of Pearl Harbor.

INTERVIEWER: You didn't go to submarine school, you said.

MR. McLEES: No.

INTERVIEWER: Did you ever go through the escape towers?

MR. McLEES: Yes, I went through that in Honolulu. Pearl Harbor had one. It was the same thing. Before I qualified, I went through that. In those days, I think our submarine pay was thirty dollars a month.

INTERVIEWER: That was probably pretty good money at that time.

MR. McLEES: Yes, it was.

INTERVIEWER: If you weren't in submarine service, what was the comparable pay at that time?

MR. McLEES: I think when I first enlisted in the Navy, my pay was \$21 a month as a recruit seaman. Then, it went up after three months. It went from \$21 to \$35 or something like that. Then, you had to make a rate before you could get up to seaman. First it was \$56. I think the highest rate there was paid to chiefs, at \$99 a month.

INTERVIEWER: Then, you left Pearl Harbor, you said.

MR. McLEES: We came back to New London on the S-30 boat. After I was in New London for a short while, the squadron got a request for four third-class electricians' mates to go to the USS *Raleigh*, a light cruiser. That was over in Europe. It was supposed to get relieved over there by the USS *Omaha*, another cruiser, but on the way out there, the *Omaha* went aground and had to go in for an overhaul. They had several people on the *Raleigh* whose time was up and had decided they were going to get out of the Navy. They wanted replacements for them. I figured I had about a year to go on my enlistment and it would be a good chance to get some overseas duty, so I volunteered and transferred to the destroyer, the USS *Claxson*. Then, we met the *Raleigh* over in Gibraltar. I went aboard the *Raleigh*. I made second class on the *Raleigh*, second class electrician's mate.

I think that just before my enlistment was up, we were relieved and came back to the States. I decided that I didn't want to stay on a surface craft. I wanted to get back to submarines. I'd already agreed to extend to go over my enlistment for two years to go over to the *Raleigh*. But when I got back to Norfolk there, my enlistment was not quite ready, so my extension hadn't started. I gave them a big line of baloney that I'd been offered a big job with Standard Oil or somebody, and I got my extension cancelled and got out of the Navy. On the way back to Kansas, I stopped in Washington. There was an ex-skipper there who told us when he left the submarine that if there was anything he could do, were he at the Bureau, to stop by and let him

know. I stopped there and told him I was out of the Navy, but I wanted to go back for submarines. He said, "You go on home. When you get ready to ship over, give me a call. I'll send a letter to the recruiting station." That was how I got back on submarines.

INTERVIEWER: What was the attraction of submarines? You already had submarine experience and then you went to the surface Navy.

MR. McLEES: Well, of course, there was the extra pay and the social relations on submarines. You knew everybody and they knew you. You were family and all that business. It was really more homelike. On the cruiser, I didn't know more than just the group in my division.

INTERVIEWER: Was it in New London where you signed back up?

MR. McLEES: I signed up in Kansas City, at the recruiting station. Then, I transferred right back to New London. I got on another submarine. I got on an R-boat, an R-14.

INTERVIEWER: Were the R-boats bigger?

MR. McLEES: They were smaller than the S-boats. The O-boats were the smallest, followed by the R-boats and then the S-boats. While I was in New London, they started to building the fleet boats and I put in for the USS *Squalus*. I got transferred to it in February of 1939 or so. It was still being built in Portsmouth.

INTERVIEWER: It was a modern submarine.

MR. McLEES: That's right. It was really something to get on one of those fleet boats, or what we called the 'fleet-type' boats.

INTERVIEWER: Were you continuing to keep your training?

MR. McLEES: While I was in New London, I went through the tank and the pressure chamber and all that.

INTERVIEWER: You were continually being educated and refreshed.

MR. McLEES: Yes. Of course, when I came to the *Squalus*, it was quite different from the R-boat or the S-boats that I was on. I had to re-qualify. Of course, on a trial run was when we went down, flooded out the boat, and laid on the bottom.

INTERVIEWER: Before we get into that, because that's a part on which I'd really like to focus, were you aware of any rescue equipment at that time? Were you aware of the bell, the rescue bell?

MR. McLEES: I was not too aware of the bell, but we did take the lung training and all that. We had that in the tank. We used the lungs to come up from a hundred feet. That was the only thing that we had.

INTERVIEWER: It was really quite an advancement in itself.

MR. McLEES: That's right, yes. To be able to come up from a hundred feet was an achievement. The tank had an escape chamber at its bottom, and you went on in there and opened the hatch and came up through the hundred feet of water.

INTERVIEWER: You transferred then to Portsmouth, I guess, where the *Squalus* was?

MR. McLEES: I came to Portsmouth, yes.

INTERVIEWER: What was your job on the *Squalus*?

MR. McLEES: I was a second class electrician's mate.

INTERVIEWER: You were going out on a daily basis from Portsmouth?

MR. McLEES: Yes. We'd go out. We went out and operated one day, and the next morning, we were supposed to make this crash dive, or whatever they called it. It was putting full power on the main engines and then shifting the motors and trying to get down to fifty feet in fifty seconds, or less than a minute, I think. That was one of the Bureau's qualifications, to be able to go down to periscope depth in so many seconds.

INTERVIEWER: Where were you during that dive?

MR. McLEES: I was assigned to the forward battery. It was going to be a one-hour full-power discharge on the battery. I was to take gravity and temperature readings every five minutes during the hour-long discharge.

INTERVIEWER: You were just forward of the control room?

MR. McLEES: Yes. Boyson was on the telephone in the forward battery. He was the one who received the word that the aft engine room was flooding. I think I was down in the tank at the time, down below the deck.

INTERVIEWER: You were in the battery.

MR. McLEES: Of course, since you had little clearance, you were done. You couldn't stand up down there. I think I came right out of the tank and passed the word, but the chief was taking readings from the individual boat meter up on deck. Of course, he was a little more qualified on submarines because he'd been on them for quite a while. He rushed right down to the tank and pulled a big disconnect switch to disconnect the battery from the after battery. The after battery was flooded and the forward battery was discharging fully into the after battery. He had one switch on each side. When he pulled one, the arc didn't break on it until he pulled the other one.

INTERVIEWER: Who was that?

MR. McLEES: That was Chief Gaynor.

INTERVIEWER: Can you just walk through your recollections of what actually happened from the time that you first started to dive?

MR. McLEES: As I said, I was down in the tank and soon as Bryce got the word that the engine rooms were flooded, the word came that we were to secure the after battery, forward battery, and

go into the forward torpedo room. They figured that we might start getting chlorine gas from the battery.

We went in the forward torpedo room, and then got word to conserve all the oxygen we could. I crawled into one of the bunks there and lay down and covered up, because it was cold. Later on, it got really cold. We had no lights or anything.

INTERVIEWER: When did the lights go out?

MR. McLEES: The emergency lights went out when Gaynor pulled the disconnect switches in the forward battery. Of course, that was one of the things that were changed. After the *Squalus* accident, when you pulled the disconnect, you still had emergency light.

INTERVIEWER: It was pitch black.

MR. McLEES: It was pitch black, yes.

INTERVIEWER: Did you have flashlights?

MR. McLEES: We had flashlights and battle lanterns. We didn't want to use them unless we had to.

INTERVIEWER: What was the sense of the crew as the flooding happened?

MR. McLEES: There was no panic or anything that I knew of. You never heard anybody start hollering and then snap. I, at least, sort of figured, "Well, what the heck, maybe we are on the bottom, but we'll get rescued in no time at all."

INTERVIEWER: That was something that you had thought through beforehand.

MR. McLEES: I guess, yes.

INTERVIEWER: You realized that it could happen?

MR. McLEES: Yes.

INTERVIEWER: The majority of the crew then went to the forward torpedo room.

MR. McLEES: Yes, they went there after they got settled down and everything. Everybody who was in the control room secured the control room and went into the forward torpedo room.

Meantime, Maness closed the bulkhead door between the control room and the after battery when that started flood. He got that closed. I think there were two fellows who came from the after battery who got into the control room before we closed the door.

I think that after the boat was raised, they found a first class electrician's mate who had been assigned to the after battery to take readings. His body was still in the after battery, and a mess cook was also still in the after battery. They never found the body of a third class cook, Thompson. He got into the skirt of the after battery hatch and was trying to open the hatch. He got it undone, but the pressure held it shut. He passed out after the air was all gone in the normal space in the hatch there. When they first raised the *Squalus* and it went back down, the pressure pushed the hatch open and they figured that his body went out through the hatch. They never found it.

INTERVIEWER: Was it just the luck of the draw that you weren't in the after battery?

MR. McLEES: Yes.

INTERVIEWER: I assume that you had served back there before.

MR. McLEES: Yes. That's right. Badick and I were sitting in the crew's mess and having a cup of coffee when the diving alarm went off. He said that he wasn't finished with his coffee yet and for me to go on forward. Because he was first class and I was second, I was to go forward and he was to take the after battery. That was why he didn't finish the after battery compartment, where he hadn't finished his coffee.

INTERVIEWER: Are most of the things written in Peter Moss' book, *Narrows*, accurate?

MR. McLEES: That one is really true to what happened. He was right out on the USS *Falcon* the all the time. I don't know if you heard the story about him or not.

INTERVIEWER: No.

MR. McLEES: They said that after the boat sank, the *Falcon*, which was a salvage ship, was there. He got some boat from Portsmouth to take him out to the salvage area. They weren't letting any of the small boats into the area, but he talked the guy on the boat into taking him up by the *Falcon* and he jumped onto the *Falcon* and made them pull the boat and shove off. Then, he got acquainted with the admiral and lived right aboard the *Falcon*.

INTERVIEWER: In fact, I think there is a chapter in his book that describes how we actually got out there.

MR. McLEES: He was later killed during the war, in a plane accident or something.

INTERVIEWER: Was he an aviator?

MR. McLEES: No. He was a war correspondent. At the time, he was with the *Boston Globe* or the *Boston Post* or something.

INTERVIEWER: Let's get back to the *Squalus*. You were going down. Maness, you said, closed the hatch, and you all moved up to the forward torpedo room and everything was pitch black. What was Captain Naquin doing at that point, or what were his instructions to you?

MR. McLEES: I guess he was the one who told us to secure the forward battery on account of the chlorine. I don't think it ever had chlorine in it, but they were afraid it would get in there. After we got that secured, the people in the control room decided to vacate the control room and go to the forward torpedo room.

INTERVIEWER: There were a total of how many people in the forward torpedo room?

MR. McLEES: Oh, I guess there must have been 33 of us, because the number of those rescued was 33.

INTERVIEWER: That had to be pretty cramped.

MR. McLEES: I guess it was, yes. I was lucky. I came up in the first bell trip.

INTERVIEWER: I've never been inside of a submarine like the *Squalus*. How big was the forward torpedo room?

MR. McLEES: It was a good-sized room.

INTERVIEWER: Were there bunks all around?

MR. McLEES: There were bunks on both sides.

INTERVIEWER: Were there bunk over the torpedoes?

MR. McLEES: There were bunks over the torpedo tubes. I think the bunks were two-tiered or something. I don't know for sure. Maybe they were just one-tiered. There were not too many bunks up there, because normally, there were about a half-a-dozen people sleeping up there.

INTERVIEWER: Was there any water in the torpedo room?

MR. McLEES: There was a little bit in that got in.

INTERVIEWER: It was water from the vents, I guess. Were the vents secured?

MR. McLEES: I don't really know whether they were or not. But there was hardly any water.

Of course, a little water got in when they first opened the hatch. When they blew the water out of the bottom of the bell, before they opened the hatch, a little water got into the escape drum there, and when they opened the lower hatch, some got into the torpedo room.

INTERVIEWER: What time was it when you actually settled into the bunk?

MR. McLEES: I would say it was around nine or so in the morning.

INTERVIEWER: It was pitch black and nine in the morning with 33 people crammed into the forward torpedo room. It was getting cold. You were not wet, though?

MR. McLEES: No.

INTERVIEWER: You were just cold.

MR. McLEES: Actually, we must have all been in the torpedo room when they made the first bell trip. We must have been. I won't say for sure as to whether we were all up there then.

INTERVIEWER: How long did it take before the bell actually arrived?

MR. McLEES: It was probably the next morning sometime, the next forenoon that the first trip was made.

INTERVIEWER: It was more than 24 hours that you were all there together.

MR. McLEES: It was about 24 hours.

INTERVIEWER: What were you doing during that time?

MR. McLEES: Oh, I don't know. They were sleeping, I guess.

INTERVIEWER: There was no sense of urgency?

MR. McLEES: No. Nobody was saying much and it was pretty quiet.

INTERVIEWER: I know carbon dioxide build-up was a concern. Were you doing anything to sort of keep it down?

MR. McLEES: Yes. We laid down one of the sheets or something, a mattress sheet or something, and spread out the carbon dioxide absorbent. It was a white powder.

INTERVIEWER: I'm familiar with lithium hydroxide. When you breathe that, the fine dust, it actually makes you start coughing.

MR. McLEES: No. I don't recall that at all.

INTERVIEWER: You didn't have any sense that the atmosphere was becoming stale?

MR. McLEES: No.

INTERVIEWER: Everything was fine?

MR. McLEES: I don't think anybody had any breathing problems. I think there was one person who was getting sick. I don't know whether it was on account of his breathing, or whether it was just nervousness. I didn't know what it was, but it was only one person. They had one of the enginemen, the machinist's mate, carry him off when they came out of the bell. They had to carry him off. His health may not have been too good anyway. He was one of the oldest fellows on the boat.

INTERVIEWER: He was actually physically sick.

MR. McLEES: Yes. They put us all in the hospital after they got us off of the boat. They put us all up in the hospital, which was against our wanting to go there.

INTERVIEWER: After you are freed from a submarine, you don't want to be confined somewhere else. What was going through your mind while you were waiting for the bell? You didn't know for sure that the bell was coming. There wasn't discussion of the bell, was there?

MR. McLEES: Well, no, there was not. But we hadn't been down too long before the sister ship, the USS *Sculpin*, came out. We could hear her screws and her engines running when they finally located us. First, they picked up our marker buoy. When they brought it on deck, the marker buoy, they tied the line around the railing and the boat swayed away from us and parted the cable. That was one of the things that they showed in the movie. It seems that the cable broke.

Swede Momsen was diving over the sides, trying to get the other end of the cable.

INTERVIEWER: That had to have burst your bubble somewhat, I guess, because you finally had communication with the surface, and all of a sudden you lost it.

MR. McLEES: They said just say "Hello, Naquin," and this and that. That was about as far as they got, just a few words. Of course, the *Sculpin* started to use their sonar. We could hear them pinging, and we were signaling back by hammering on the hull the dot-dash.

INTERVIEWER: In Barrow's book, or Peter Moss' book, it talks about how fatiguing that was.

MR. McLEES: I don't remember that at all. I don't think we were using as big a hammer as they write about. In the movie and the book we use a big maul to hammer with.

INTERVIEWER: Spirits were still high?

MR. McLEES: Yes, they seemed to be high, very much so.

INTERVIEWER: Did it ever go through your mind that you might actually have to make an escape?

MR. McLEES: I guess they were talking about that. In fact, they had us, the skipper or whoever it was, put on the lungs. We had the lungs strapped on.

INTERVIEWER: Was that due to the potential for chlorine?

MR. McLEES: No. It was done just to be prepared. They figured that at a hundred feet or so there, with the temperature of the water, we wouldn't have much chance.

INTERVIEWER: You said that it got very cold in there. What do you think the temperature was?

MR. McLEES: I don't know what the temperature was. I don't know, but it must have been forty degrees or less. I don't know. It was really cold down there.

INTERVIEWER: You were being told, I assume, to be very still.

MR. McLEES: Yes. I know that I was lying in a bunk. In fact, there was another guy lying in the bunk, too. We had a big cover and blankets over us to keep warm.

INTERVIEWER: Finally, they located you again after the parting of the line.

MR. McLEES: Yes.

INTERVIEWER: The *Falcon* wasn't there yet.

MR. McLEES: No. She wasn't there yet. The *Sculpin* was the only craft that was there. I think the *Sculpin* located us the first day. The *Falcon* ended up the next morning sometime.

INTERVIEWER: I want to get to the escape, but were you aware of the S-50, S-51 or the other submarines that sank before?

MR. McLEES: No. I don't think so. I don't remember anything about them.

INTERVIEWER: The scenarios were not that different. Well, of course, I guess both of the others were actually collisions, but they were in murky, shallow water. They were in very similar situations. Of course, none of them got out.

MR. McLEES: That's right, yes.

INTERVIEWER: But you weren't aware of those?

MR. McLEES: No.

INTERVIEWER: I suspect that would have changed the spirits of the crew quite a bit.

MR. McLEES: I don't remember seeing even the escape bell before.

INTERVIEWER: That wasn't a routine part of the training?

MR. McLEES: No.

INTERVIEWER: The *Falcon* finally arrived the next day with the bell.

MR. McLEES: That's right, yes.

INTERVIEWER: Can you describe what the operation for the actual escape was?

MR. McLEES: I think as soon as the *Falcon* arrived and they made the mooring over our area, the crew from the *Sculpin* actually went out in the small boat and used the grappling hook and located us after the cable for the small buoy had broken. They located us with the grappling

hook. The grappling hook so happened to hook on the railing of the forward torpedo room hatch. Of course, when the diver came down on that line, he landed right by the hatch, which was where he was supposed to be. It made it very easy to hook onto the hatch area.

INTERVIEWER: The first bell came down the next day. About what time was that?

MR. McLEES: I can't remember what time it was, but it must have been around noon or before noon.

INTERVIEWER: It was close to thirty hours then, about 28 hours after the sinking.

MR. McLEES: That's right, yes

INTERVIEWER: Do you recall when you first heard the diver hit the deck? Could you hear the diver up there?

MR. McLEES: When they came down to put the cable on, you could hear him walking on the deck.

INTERVIEWER: That had to raise your spirits.

MR. McLEES: That's right. He was easy to hear because divers wore those big lead-loaded shoes. He went clunk, clunk on the deck. Another good feeling occurred when they opened the hatch and the guy from the bell hollered down. In the movie, it showed Swede Momsen was the one who took the bell up and down, which he didn't do.

In fact, the guy who was operating the bell was a Polish fellow, Mikalowski or somebody. I forget what his name was. In fact, I did a television movie with him in 1938 or sometime.

INTERVIEWER: What was this movie about?

MR. McLEES: It was called *Place the Face*. It was just like one of the game shows. I was a guest. No, that was after the war, by golly! It was after the war that they had that. I was in New

London in the 16th fleet then. I got a call from Hollywood, and a guy wanted to know if I would come out and do the movie. I said I would if my wife could come with me. He said okay.

Anyway, went out there and did this movie. I was on TV there, and they were asking me questions about this and that. They had this fellow. You saw his picture as though it was in a picture frame. You just saw his head. They were asking questions, like from where I knew him and all that. It just so happened that he was one of the divers who had made the dive to the *Squalus*. His name was Mikalowski.

INTERVIEWER: What was the first thing he said to you when he opened the hatch?

MR. McLEES: I don't remember that.

INTERVIEWER: I think in the book there were certain statements like, "Did you bring down a steak?"

MR. McLEES: Yes, and "What took you so long?" was another. I remember that the movie showed Swede Momsen over the hatch, though he never went down there.

INTERVIEWER: Was it very organized? What determined who went up first?

MR. McLEES: Well, the captain was the one who assigned guys to go up. He'd say, "You, you, and you," just like that.

INTERVIEWER: I know that in the book it said that he wanted to have an officer go up on the first ride so that the officer could describe the situation.

MR. McLEES: I think Lieutenant Doyle was the first one. Maybe he was, maybe he wasn't. I don't know. In fact, I'd been with Lieutenant Doyle before. He was on the S-30 boat when I came back to New London.

INTERVIEWER: You climbed up the ladder into the chamber.

MR. McLEES: Yes.

INTERVIEWER: Then, they closed the hatch. It had to be very cramped, right?

MR. McLEES: Yes. I forget how many could get in there. It had room for four or five. I guess there must have been eight or nine in there, plus the operator. Then, they'd close the hatch going from the escape place down in the torpedo room. They closed the lower hatch. Then, they would flood the chamber and open the upper hatch into the bell. The people down in the torpedo room, with a big lever they had there could close that upper hatch of the submarine after the bell had left, and they could then drain the escape chamber and open the lower hatch so that people could go back up in there again.

INTERVIEWER: What was the whole operation like, from leaving the *Squalus* to getting to the ship?

MR. McLEES: It probably took no longer than 15 or so minutes, or that was what it seemed like. We moved right along. We didn't have to stop for decompression or anything like that. We moved right on up, slowly.

INTERVIEWER: Were there any ports? Could you see outside? Could you see the *Squalus* as you were leaving?

MR. McLEES: No. I don't think so. I don't believe there were any, none that I know of anyway.

INTERVIEWER: You got to the surface and they were able to open the hatch.

MR. McLEES: They were able to open the hatch, yes.

INTERVIEWER: What were your thoughts when you got out?

MR. McLEES: Like it said in the movie, I said something about the fresh air and the sunshine.

INTERVIEWER: It had to be quite a contrast, after breathing that relatively stale air.

MR. McLEES: That's right, and we had been in darkness.

INTERVIEWER: When you came up, it was a bright sunny day?

MR. McLEES: I remember now. It was a bright sunny day.

INTERVIEWER: You arrived in heaven.

MR. McLEES: That's right, yes.

INTERVIEWER: Did they keep you around after you got on the *Falcon*? Did they keep you there?

MR. McLEES: No, we weren't there too long. I think that after they got the first two trips aboard, the Coast Guard took the first two loads of us to the hospital.

INTERVIEWER: You weren't out there when the fourth trip came up?

MR. McLEES: No. We were at the hospital by then.

INTERVIEWER: Do you recall what happened? I'm sure you heard about what happened on that fourth trip?

MR. McLEES: Yes. They had trouble with the cable. It was almost parted.

INTERVIEWER: Who was in the last party?

MR. McLEES: It was Boyce, Pearce, Pursico, and I don't know who the rest were.

INTERVIEWER: Obviously, Naquin was one of them, I guess.

MR. McLEES: Naquin was one. He was the officer. He was the captain. He stayed until everyone else was able to go up.

INTERVIEWER: How long were you at the hospital?

MR. McLEES: I think that right after we got in the hospital, Harold Prebel, the civilian naval architect, started to get on the phone and we had more food and stuff coming up to that hospital. He actually ran the Navy Yard, almost, I think. What he said really went. We got more stuff coming up there. People were bringing stuff in.

INTERVIEWER: Were you married at that time?

MR. McLEES: No. I hadn't even met my future wife.

INTERVIEWER: I'm sure some of the crewmembers were married. Were the wives and the families trying to get into the hospital?

MR. McLEES: I don't remember any. I don't know. I don't think there were many guys who were married. But there were some. I don't even remember anybody coming to visit while we were in there. There was no one I knew of, anyway.

INTERVIEWER: I suspect that the press was trying to get to you at that point.

MR. McLEES: I know that right after we got out of the hospital, they were. They had so many telephone lines running in there, from the outside into the Navy Yard and to the main building. After we got out of the hospital there, we weren't allowed to leave the area until after the inquiry.

They had the inquiry there, and they found out the accident was by no fault of the crew or anything. I had bought a car from the first class electrician named Bland, but I forget what kind of car was. It was probably a hundred bucks, and I probably gave him a ten-dollar down payment on it and was supposed to give him so much every payday. I don't know whether I said it or whether he just made it up as a joke. The first thing I supposedly said to him when we got together after getting off the *Squalus* was, "Gee, you would have to be one of those who were saved," because I owed him money. He made quite a joke out of it. Every time we had a convention later on, he'd tell that joke.

INTERVIEWER: Did the crew stick close together after that?

MR. McLEES: Yes, we did.

INTERVIEWER: I know you've had several reunions.

MR. McLEES: Right after that, they had a big memorial for us out here. Where was it? Hampton Beach? No. It was right out around Rye. Yes, it was right around Rye or someplace that they had

a big memorial service. Some big shot had a big mansion out there. They had a big orchestra playing and all that, right there on the beach. The brewery in Lowell, Massachusetts, the Harvard Brewery, threw a big party for us.

INTERVIEWER: That was immediately after the accident?

MR. McLEES: It was shortly after, before anybody got transferred. I know there was about a dozen or so of us who went down to the Harvard Brewery. They gave us a big dinner and all the beer we could drink. I got a kick out of it. When we got ready to leave, I had my car and was driving. A couple of us had cars. We got ready to leave. We gave the guy the 'heck, you know,' because we were trying to get about three or four cases to take back with us. We were calling them cheap and everything else for not giving us any beer.

INTERVIEWER: Were you at all involved with the salvage operation of the *Squalus*?

MR. McLEES: It probably wasn't long after we first started before they sent us out. We'd come in at night and go back to sleep in the barracks and go back the next morning via the Coast Guard. They had a small Coast Guard boat that operated back and forth.

We'd go out there, and they had us handling the hoses because they had all of these hoses hooked up to different salvage compartments, fittings and buoyed out. We got to bring them back in every morning and every day. They'd hook them up to the air manifold and check the pressures to make sure they still had pressure on them. That was our job. A lot of times we'd go out in the morning on the Coast Guard freight boat, stay aboard there and come right back in with it. Out there, nobody really knew who were.

INTERVIEWER: I know the famous picture of the *Squalus* with the bow up. That had to be very heartbreaking.

MR. McLEES: It was hard.

INTERVIEWER: I was in San Diego a couple of days ago, and I was interviewing Rear Admiral Brad Mooney. He was telling me that when he was eight years old, he was living here, in Portsmouth, New Hampshire. For some reason, his father took him out there that morning when the bow came up and sank.

MR. McLEES: When I went down to Annapolis, I had quite a talk with him. I didn't know who he was. I had never heard of him. He was telling me about some of the experiences he used to have up here, and asked whether I knew this gal or that gal.

INTERVIEWER: I assume there were a lot of boats around there.

MR. McLEES: Yes.

INTERVIEWER: It was this whole salvage operation.

MR. McLEES: Yes, there were a lot of boats there. There were planes flying over. People were getting with reporters. A lot of times, the Coast Guard boat would pick us up in the morning and take us out to the area. We'd actually go aboard the *Falcon* and make sure the skipper and some of the others saw us and then we would get back aboard the Coast Guard boat and hide down in the engine room and ride that back in. That Lieutenant Sharp, he was the skipper. He was pretty good. But like in the movie, now, *The Terrible Hours*, Smerge showed him with a chief petty officer signature on his hat. That was one of the things that I noticed.

INTERVIEWER: Hollywood messed up.

MR. McLEES: Yes.

INTERVIEWER: How long did it take from the sinking to actually resurface the *Squalus*? It was several months, wasn't it?

MR. McLEES: We went down on the twenty-third of May. I think it was September before they got the boat back into the shipyard.

INTERVIEWER: Were you there?

MR. McLEES: Yes. The skipper was going to have all of us go out there and ride the boat back in. Of course, they never got her out of the water far enough that we could ride her in. We were going to clean the deck all off and everything else when they brought her in.

Anyway, we were there when they brought the boat in. We were right at the pier at the Navy Yard. As soon as they brought the *Squalus* in and tied it up alongside the pier, they had these big tripod cranes on the pier. It seemed as though the deck was half-underwater. They hooked it onto the sail, cut a hole in the sail and hooked the cable in there to straighten the boat, and as they pumped the water out, they brought it up. As soon as they got the bow out of the water, we opened the torpedo room hatch, and I went back down as far as the after battery but didn't go in the control room.

INTERVIEWER: Did you have flashlights?

MR. McLEES: Yes, we used flashlights.

INTERVIEWER: That had to be a stressful experience.

MR. McLEES: That was, yes. We were living in the barracks then, I guess. They sent us all off the boat before they started taking any of the bodies off that night. None of us were around there then.

INTERVIEWER: All of the human remains were still in there after three months.

MR. McLEES: Yes. They said that the bodies were in good shape because they were in that cold water all that time. I escorted Ciphers' remains back to Abingdon, Virginia. He was the first electrician's mate

INTERVIEWER: You were a very good friend. That's what part of being in the Navy is about.

MR. McLEES: I think the only relation he had was his mother. I remember when we got into the funeral home there, his mother couldn't get it through her mind that that was her son, because the caskets were sealed. Actually, I saw her point. After I left the funeral home and went to my hotel room that night, I think she finally convinced the undertaker at the funeral home to open the casket so she could make sure that was her son in there.

INTERVIEWER: The surviving crewmembers escorted the bodies to their hometowns. Each person escorted someone different.

MR. McLEES: Yes. We left Portsmouth by train to Boston. Then, they had to go from North Station over to South Station and you had to make sure the casket got on the train that you were on and everything.

INTERVIEWER: Was it the responsibility of the surviving crew to go into the *Squalus* and refurbish it?

MR. McLEES: All we had to do was go in and get all of the personal gear off the boat and all of the portable equipment, like typewriters and stuff like that. We took all of that stuff off and put it in a storeroom. We went through all of the lockers and got all of the personal gear of the deceased so that we could give it to their dependents.

INTERVIEWER: What was your feeling as you went back in there?

MR. McLEES: Well, it was kind of scary.

INTERVIEWER: I would imagine it would be. After the *Squalus* was refurbished, it was actually renamed and sent back out, I understand.

MR. McLEES: Yes. It was renamed the USS *Sailfish*.

INTERVIEWER: Did you continue in the submarine service after that?

MR. McLEES: In fact, I fought hard and finally got it. There were three of us who went back on it as the *Sailfish*.

INTERVIEWER: You were back on the *Sailfish*?

MR. McLEES: Yes. The three were Gunner's Mate Cravens, Torpedoman Maderas and myself. The three of us went back on it as the *Sailfish*. I made the first several war patrols on it as the *Sailfish*.

INTERVIEWER: You had no hesitancy, or you didn't have any concerns after going through that experience?

MR. McLEES: No. I just wanted to get back up to Portsmouth, because I was due to get married shortly. In fact, I came back to Portsmouth in 1940. I got back in toward the end of 1940 and got married in January of 1941. The boat left again in February. We left for Pearl Harbor then. My wife was supposed to come out to Pearl Harbor after we got settled, because that was going to be our home base for the *Sailfish*.

Of course, sometime around October or November, the *Sailfish* got orders to ship to the Philippines. We had to cancel the idea of her moving out there. We were in Manila when the war started. We went out right away. We went out the next day. The first day after the war started, we lay on the bottom of Manila Bay while the Japanese were bombing Manila.

Then, we went out and started to operate, and right about the second or third day of the war, cloaked in the dark, we started out to someplace and contacted the Japanese destroyers. We fired on them and got a hit, an explosion, but we couldn't see what happened because we had to go deep. An underwater sound started. The officers had been told the Japanese didn't have underwater sound equipment, so the Captain got it in his head that maybe he had fired on one of our own destroyers. He cracked up. The Executive Officer had to bring the boat back into

Manila. We came in about midnight and, of course, everything was blacked out. When coming into Manila, Baylor flashed a light on one of the buoys for a few seconds. We headed for that. Then, on the next buoy down, he flashed a light. I know I was on the controllers in the maneuvering room and was getting an 'all ahead full, back down full' all the way through there.

We finally got into there and tied up, but the tender was still there. The next morning, they called us all up to quarters, and the captain had big tears in his eyes, and he told us that he had cracked up and the execs had brought the boat in. We were then given the captain of the *Sea Lion*. The *Sea Lion* was alongside in the Cabiti Navy Yard. She was being overhauled and wasn't able to get underway. When the Japanese bombed, they got a direct hit on the after engine room and sank it right alongside the dock. They lost several of the crew. We got the skipper, Lieutenant Bogey, and he became skipper of the *Sailfish*.

INTERVIEWER: I notice the *Sculpin* had a sister boat in the *Squalus*. There was a relationship between the *Sailfish* and the *Sculpin* in World War II, wasn't there?

MR. McLEES: Yes.

INTERVIEWER: Do you want to talk about that? Wasn't the *Sculpin* sunk?

MR. McLEES: The *Sculpin* was sunk and then the crewmembers were taken prisoners of war. They were put on a Japanese aircraft carrier to take back to the mainland, I guess. While they were headed there, The *Sailfish* came in contact with this aircraft carrier, not knowing that there were any Americans prisoners of war aboard, and sank it. A good friend of mine, George Roshek, was one of the only survivors. I still contact him all the time. He is down in Florida, but he's in pretty bad shape. His legs are all banged up and everything else. He used to come to all of our conventions, but I haven't seen him for several years.

INTERVIEWER: I've got an interview that someone else did with him during on which he tells his story.

MR. McLEES: He's a very nice fellow.

INTERVIEWER: You were on seven war patrols?

MR. McLEES: Yes, I was on the first seven war patrols. I wasn't on the *Sailfish* when it sank the carrier. I had already gotten off. That must have been on the eighth or ninth war patrol. I don't know which one it was. I got off when the boat came back to Maui, after the first seven war patrols, for an overhaul.

We were due to get an overhaul in Pearl Harbor. We came into Pearl Harbor one day and that afternoon they transferred all of us but one section, up to the Royal Hawaiian Hotel. We probably got there in the evening. On the next morning they called us back to the ship. The overhaul at Pearl Harbor had been cancelled and changed to San Francisco. We got to San Francisco after we'd been there about maybe four or five days, I got orders to go to Portsmouth to commission the USS *Crevalle*. I put in time on the *Squalus*, the *Sailfish*, the *Crevalle*, and the *SeaLeopard*. The *Sailfish* was the 192. The *Squalus* was also the 192. They didn't change the number. I went to the *Crevalle*, the 291. When it first started out, the *Squalus* was the S-11. Then they changed the hull number to 192. I think that one of the TV movies, the first one, showed it as an S-11. It showed the *Squalus* as an S-11, I believe.

INTERVIEWER: Now, going back to those war patrols, were there any times during those patrols that you were being depth charged?

MR. McLEES: Yes.

INTERVIEWER: Can you tell us what that was like?

MR. McLEES: Heck, we got depth charged on the first trip out. After we went out and fired on the destroyer, we got depth charged. But it wasn't too bad. In fact, there, I think before the war we didn't get any depth charges. I didn't remember any, anyway. In Pearl Harbor, they would take a boat out and tell it to dive to maybe a hundred feet. They had this destroyer dropping depth charges. But you could barely hear them; they were so far off.

INTERVIEWER: Was that just to get you familiar with depth charges?

MR. McLEES: Yes. But we had several pretty close ones during my time. I made three runs on the *Crevalle*, so I had a total of ten patrol runs. On the third run on the *Crevalle*, we were operating someplace off the Philippines. We got word to go into some bay or something and pick up some American survivors. We pulled into this, and I can't think of the name of it, but it was someplace in the Philippines. We pulled into the bay and they told us if everything was clear, there would be a big white sheet on the side of a mountain there. We saw that, pulled in and then surfaced. We were surfaced for no longer than about five minutes when what we called 'bug boats' headed out toward us and we took aboard thirty-something passengers, I think. They were American women and small kids. We took them aboard and brought them to Australia. I forget where in Australia. During the time that we had them aboard, we got one of the worst depth charges I took in all ten war patrols.

INTERVIEWER: Can you describe what it was like to take a depth charge like that?

MR. McLEES: Well, you were down there. You were hanging onto something. The old boat shook and water started dripping in here and there. A valve ruptured or something. The kids were getting a big kick out of it. They were hollering, "Did we hit them? Did we hit them?" every time a depth charge went off.

INTERVIEWER: The kids weren't afraid at all.

MR. McLEES: No. They didn't know the difference. To this day, at our national convention every year, several of those people that we picked up that come. They are all American citizens. They say their husbands were out there on business or something. They spent days out in the wilderness trying to get away from the Japanese.

INTERVIEWER: After three patrols on the *Crevalle*, you came back to Portsmouth.

MR. McLEES: I came back and put the *Sea Leopard*, 483, into condition. I was on the *Sea Leopard*. We were in New London training, ready to head for the war zone when the war ended.

INTERVIEWER: I would think that after having survived the *Squalus* sinking, depth charging and World War II for some time, you might think that it was probably time to give it up.

MR. McLEES: Of my 22 years in the Navy, all but about 8 months were spent on submarines. In fact, even then I didn't have enough. After I retired, I went back to Portsmouth and worked for 13 years out in the shipyards.

INTERVIEWER: You did that as a civilian?

MR. McLEES: Yes.

INTERVIEWER: You've lived here in Portsmouth since the war?

MR. McLEES: Yes. My wife is from here in Portsmouth, so this is where we settled. In 1948, when I got out of the Navy, I had this house built, and I retired from the Navy in about 1956. In about 1960, the state decided it was going to build a new highway through where the overpass is there, and that was where my house sat, right on the corner where the overpass is now. I had to pick it up and move it to here.

INTERVIEWER: I'm sure this area has grown considerably since World War II.

MR. McLEES: Yes. This was the second house in this area. There was nothing here.

INTERVIEWER: It seemed that after the symposium, Helen Hart Momsen has a very close relationship with you and Carl Brightson.

MR. McLEES: Yes. In fact, I didn't even know her until I went to the symposium.

INTERVIEWER: Is that right?

MR. McLEES: I had never met her or talked with her. Her father was there, wasn't he?

INTERVIEWER: Yes. I got the feeling that it was almost like a family.

MR. McLEES: No, but down in Washington, she was there then. I don't know whether she came up for the christening of the USS *Momsen*.

INTERVIEWER: I think she did.

MR. McLEES: One of the grandsons or something is a crewmember, a fire control man. In fact, about three weeks ago, the USS *Albacore* had its fiftieth anniversary, I guess, so they had a little shindig over there. There were eight or ten people from the *Momsen* there for that and this kid was there.

INTERVIEWER: It's been 64 years, I guess, since the *Squalus*. It sounds like you've had a very colorful and exciting career.

MR. McLEES: Yes, I've had a very good career, I think.

INTERVIEWER: Is there anything else that you'd like to share?

MR. McLEES: Well, I'd like to say when I got invited down to Washington, the producer, the guy who produced the show, was the one who invited us survivors down. In fact, it was only Bryce and me. My daughter and I went down, and we had dinner at the White House, out on the White House lawn. They had tables set up. We sat down out there and the guy started coming around asking, "Do you want a beer or wine or anything?" We sat there and had a few drinks, and there were several senators and representatives with whom we shot the breeze. Then,

President Bush came out and we had dinner. We had a very nice visit with his wife.

INTERVIEWER: It is a picture of President Bush. That's great.

MR. McLEES: That was in June of 2001, I guess.

INTERVIEWER: That would have been 62 years since the *Squalus*. You were married. How many children do you have?

MR. McLEES: We have no children. We adopted my daughter after I retired in 1956. She was 8 months old. We had to go all the way to Canada. I was too old to adopt in the United States, so we went to Canada, to an orphanage there. Now, she takes care of me.

INTERVIEWER: They always say that adopted children are the most loved children. They were handpicked.

MR. McLEES: Yes. I can remember that my wife and I went up to Canada that day and went to this orphanage. There was a tremendous big room with many beds and many kids. It was a Catholic home and a Sister brought my daughter out. She was all dressed up in a nice dress, 8 months old. The next morning we went to pick her up. When the sister brought her out, the sister had big tears in her eyes.

INTERVIEWER: There is one other question I'd like to ask you. You saw, at the symposium, the systems that are being developed for submarine rescue. Do you have any thoughts on these new systems that are being developed?

MR. McLEES: The one that I couldn't get over was this diving uniform that they have now, the diving suits with helmets and everything. That's something.

INTERVIEWER: There's been a lot of advancement.

MR. McLEES: Well, I guess so. I think I've got a picture of a chamber there. Is what it is, a decompression chamber?

INTERVIEWER: Yes.

MR. McLEES: I have a picture of Scott Carpenter and myself, too.

INTERVIEWER: I'll be sure to send you that book when I get back to Annapolis, because it's got a lot of the photographs from the symposium. It's very nicely done and I think you'll enjoy it.

MR. McLEES: I still have a couple of the little pamphlets they put out, the programs.

Remember the pamphlets with the people who spoke? I still have a couple of them. Then the Navy Yard, I don't know, must have got sent to the Navy Yard, give me a picture that picture that's always showed there of the symposium there. I don't know what that is.

INTERVIEWER: Yes. That's actually the front cover.

MR. McLEES: Yes. I really enjoyed that.

(Whereupon, the INTERVIEW was concluded.)

UNDERSEA & HYPERBARIC MEDICAL SOCIETY

ORAL HISTORY OF THE MAJOR PARTICIPANTS  
IN U.S. NAVY UNDERSEA TECHNICAL DEVELOPMENTS

GENERAL DISCUSSION AND  
INTERVIEW OF LEONARD GREENSTONE  
WITH JACK TOMSKY

## PROCEEDINGS

INTERVIEWER: Leonard, where were you born?

MR. GREENSTONE: I was born in Los Angeles, California.

INTERVIEWER: Tomorrow's going to be something.

MR. GREENSTONE: It's going to be my birthday. I'll be eighty years old tomorrow.

INTERVIEWER: Welcome to the ninth decade.

MR. GREENSTONE: By the way, at one time, I thought that I was the youngest person involved in the salvage of the *Normandie*. I have found out since that there were several guys there who were younger than me by one or two years.

INTERVIEWER: You were 18.

MR. GREENSTONE: Yes. That's right.

INTERVIEWER: Did you play sports or participate in any extra curricular activities in school?

MR. GREENSTONE: I participated in sports, but not too successfully. With extra curricular activities, I really a dunce. Most of the guys had extra curricular activities, which I would have enjoyed. I didn't have any.

INTERVIEWER: Where was school?

MR. GREENSTONE: I started, of course, at John Mere Junior High School after I was kicked out of McKinley Junior High School. I went from there to Jefferson High School. I was kicked out of Jefferson High School. Then, I went to Manual Arts High School, where I had to leave in my B semester prior to graduation, which I finalized at age sixty. I became a graduate of a high school at the age of sixty, with a few college courses prior to doing so.

INTERVIEWER: What influenced you to join the Navy, and what year was that that you went into the Navy?

MR. GREENSTONE: I went into the Navy in 1942 as a transfer from the California National Guard which I got out of to become a sailor. I think it was a matter of my uncle being in the Navy for twenty years, I guess, at that time. He finished up another fifteen years after that. He spent a lot of time in the Navy. My purpose for going into the Navy was getting out of the National Guard.

INTERVIEWER: We'll clarify any gaps in history of naval forces. Let's get into diving.

MR. GREENSTONE: Ah, it was sort of like being in the wrong place at the right time, I guess.

When they shipped me to Pearl Harbor in 1942, I went to the Navy yard, and while I was there, a truck had backed into a fire hydrant. By the way, we were all in line, ready to be shipped someplace in the world to do our thing in the Navy. The guy who was running the program at that time was a Lieutenant McKegan, who was in the yard. Water was shooting up everywhere. He was running around, making all kinds of noise and trying to get the thing shut down. I walked over to him, as this humble little kid, and said, "There's a valve on each side of that fire hydrant. All you have to do is dig down and there's a flat head valve. You just turn them contrary to the flow of the pipe. You'll shut that system off." Then, he used nasty language to tell me to get off my behind, go down there and get it done, if I could do it. We got a couple of guys and dug some trenches around the valves. We got the valves and the water turned off. They would have put me to work the following day out on the docks, cleaning up all the mess. At that time, he had no intention of putting me -- but that was not the way it happened. The next morning I went out at his direction, and I met some guys out there of whom you probably know. There was the gentleman who later wound up being a commander. Ed Reimer had a vessel that he had taken over out in Pearl Harbor. They had converted it into a diving boat. There were four of them on the boat. I was out at the docks. They came in and picked me up. They were going out to the USS *Oklahoma* that day. I went out with them as a ride, as a worker, to help clean up some of the mess. They were dressed in the diving

gear. I was watching them with a lot of enthusiasm. They asked if I cared to get involved, although I wasn't too anxious. But the other guy who went along with me volunteered me. They dressed me and put me in the water. They sent me down with what we now know as a descending line, attached to a particular area of the vessel where you were supposed to go into the water. They gave you this little bag that had holes on the bottom. You were supposed to pick up all the junk, throw it in the bag and signal them. They brought the bag back up sent you another. Well, I didn't get very far. I got to the bottom and said, "This isn't for me. Jewish boys don't go for that kind of stuff." My father told me that one thing Jewish boys don't do is that they don't cry when they're frightened. I just peed in my pants. I decided I could hardly wait to get out of there, and they brought me up. I figured that was the end of my diving career. Then, Ed asked, "Are you coming in tomorrow?" I said that I had no idea. He said, "Yeah, show up here tomorrow at 0700 hours." I said, "Well, there must be something with that." That started my diving career. He then got me involved and kept me moving in the water. We had the opportunity to get through. From that day on, some of the more involved and memorable activities happened with the vessels that were still there.

INTERVIEWER: Heavy gear?

MR. GREENSTONE: Yes. The first time I ever dove, I dove in full dress. I had no knowledge as to what diving was, other than jumping off a board and doing fancy things with your hands and feet. After some five or six days of working together, they decided to send me over to the submarine base to get some training so that I wouldn't be a disaster to them, I guess. At least they'd have the backup to prove that I had some practical or educational experience to help me do what I was doing. But it was not to offend anybody. It was a partial thing anyway. I'd go to the Navy base. They would teach us some of the physics and physiology and stuff that they were involved

with. I'd go to school for three, three and a half, four hours, and then go back out and go to work.

That went on for some three to four weeks, I guess.

INTERVIEWER: That was at Pearl Harbor?

MR. GREENSTONE: It was at Pearl Harbor, yeah. They ultimately classified me as a second class diver. I never took a test. I got a funny looking document.

INTERVIEWER: You completed the course.

MR. GREENSTONE: I completed the course, right. Thanks.

INTERVIEWER: That was all it required.

MR. GREENSTONE: Yes. But I got the opportunity and memory. Some of the memory was worth remembering. I got a chance to work on the *Oklahoma* and the USS *Oglala*. I had a lot of time on the *Oklahoma*. The *Oklahoma* was the one vessel they were still working pretty diligently on and trying to get it cleaned. There were ugly things that were going on in the *Oklahoma* at the time. Of course, I also met Frank Prepazich, who was a second class diver and doing salvage work there. Prepazich was going back to New York. He was the guy who told me that I should really apply myself. He actually gave me the idea that I could get back to the States by going to New York to work on the *Normandie* because they were looking for people like me, he said. I applied. It didn't take very long, only a couple of months. I was back in New York at Pier 92, which was where we lived. We marched from Pier 92 to Pier 88 every day. That was how I got involved with the *Normandie*. It was really because of Frank Prepazich. I guess that when I first got there, I found it exciting. The training was a lot different. They took a guinea pig and created problems when they did not ascend properly after time on the bottom. The little guy got bent. After you watch him for awhile you understood the dangers. They spent a lot of time with us. You have to remember that

they were trying to develop divers at pier 88 quickly because they needed them. You went back to work where you came from.

INTERVIEWER: What was the most difficult part of that diving?

MR. GREENSTONE: I think it was the change from Pearl Harbor, where we had sedimentation, but it was nothing like New York. In New York, when you went into the water, you buried yourself in mud. I think the difficult time for me was -- contrary to most, from what I had talking to the people I knew who have gone through one of the diving programs, they were restricted from blowing themselves up. Every one of us had to blow ourselves up. You got into the mud. Then, they taught you how to work your way out of it by working your chin button and kicking around until you freed yourself by creating buoyancy in your dress. Once you get out of there, you were on your way up. Then, you had to dump your gas as fast as you could so you didn't just go to the surface and explode. You tried to learn to control your ascent to the surface without having assistance.

INTERVIEWER: Do you have any questions of him?

MR. TOMSKY: Well, no. There's a danger to making yourself light -- your arms may go out and you can't use them.

MR. GREENSTONE: You might have no control.

MR. TOMSKY: You couldn't get your hands back to your control valve. All you had is your chin button.

MR. GREENSTONE: Well, you couldn't reach it sometimes.

MR. TOMSKY: But you couldn't control your air coming in. You were going to the surface.

MR. GREENSTONE: Yes, and you also couldn't control it going out.

MR. TOMSKY: You were going to blow...

MR. GREENSTONE: You couldn't get to the button to dump your gas and make yourself heavy again.

MR. TOMSKY: The danger of blowing up was twofold. First, obviously, there could have been something up above and you hit it. Second, you could rupture the suit, fill up with water, and down you would go.

MR. GREENSTONE: Yes. I don't know if this is totally true or not, but I understand that no other diving educational program provides that. As a matter of fact, most of them disallow it.

MR. TOMSKY: That's true.

MR. GREENSTONE: Yet, in salvage, everyone had to participate controlling themselves out of the mud. You didn't try to wiggle yourself around and have somebody help you up. You made it to the surface on your own. There were many who came out spread eagle on the surface. Through the graces of the good Lord, they didn't blow their dresses to kingdom come, and/or their own lives. You were told and shown the kinds of problems that could take place if you screwed up. Most of the guys handled it pretty well. Yes, there were some mistakes, but nobody died or got hurt.

MR. TOMSKY: But you learned to work in mud.

MR. GREENSTONE: There was nothing like it.

INTERVIEWER: What do you think of the beginning of salvage diving in the Navy?

MR. TOMSKY: That was on the *Normandie*.

MR. GREENSTONE: I really think that salvage diving began in Pearl Harbor. I think the work we did on the *Oklahoma* was salvage work. I was not the ship fitter. I wasn't a great welder. They didn't teach us as well as they taught us at Pier 88. But we learned to weld. You have to remember that the burning tools and equipment that we were using in Pearl Harbor were greatly increased in

their proficiencies at Pier 88 because the guys there were experimental. They developed equipment that we didn't have in Pearl Harbor.

MR TOMSKY: Salvage diving was created by necessity. In the Navy, there was deep sea diving, which was primarily mixed gas and submarine class divers who were restricted, I think, to ninety feet. I don't recall, but when you got into the war and salvage became obvious, it was necessary to then create another group of divers. Pier 88 and the *Normandie* happened to be the schools that became available to create the Navy Salvage Diving Corps.

INTERVIEWER: Was that with Admiral Sullivan?

MR. TOMSKY: That was Admiral Sullivan's group. He was a commander at the time. When he took it over -- in the Navy of salvage diving.

MR. GREENSTONE: Yes.

SPEAKER: You had salvage divers.

MR. GREENSTONE: Salvage diving in the Navy actually started it before Sullivan got there, but Sullivan really started the Navy program.

MR. TOMSKY: He also got the Bureau of Naval Personnel to designate another diving entity named 'Salvage Divers', second-class divers, salvage divers, who could go, I think, to 150 feet, and deep-sea divers, who were the mixed gas divers.

INTERVIEWER: Were they related to what the British called clearance divers?

MR. TOMSKY: Clearance divers were SCUBA, like our EOD, and were related to our EOD group of divers created. EOD and SEALs were created because there was a need. The *Normandie* became the *Lafayette*, and the troop ship. But the salvage navy was designated at that point. That was 1942.

MR. GREENSTONE: The very first document given out for a Navy salvage certification was in February 1943.

MR. TOMSKY: Okay.

MR. GREENSTONE: You had schools going and the whole bit, but there was no written certification. I got my certification for February 22nd, 1943, by mail.

MR. TOMSKY: You had the designated divers, the first-class diver, who had the insignia, the second-class diver, who had the same insignia, but with a second on it, and the salvage diver, who had the same insignia with an S on it. You had those three categories of divers, and the salvage diver was the last one to come along. The basic training facility was the *Normandie*.

MR. GREENSTONE: Yes. Where you got certified was from an educational program or a school, where they trained you. It was, of course, the *Normandie*. Nothing existed before. A fellow named Sullivan was working for Merritt, Chapman, and Scott.

MR. TOMSKY: He worked for the Navy. He was a Lieutenant Commander in the Navy. The Navy had a contract on the east coast with Merritt, Chapman, and Scott, and on the west coast with one of the maritime groups on the west coast. It might've been Murphy - Pacific. It was one of the groups on the west coast. The navy didn't have any salvage capabilities, so they had this contract with the east coast group, Merritt, Chapman, and Scott. Sullivan was the Navy's liaison officer to monitor that contract.

MR. GREENSTONE: Most of his salvage experience, up to that time, really came from England.

SPEAKER: Yes. He had very little.

MR. GREENSTONE: He had very little, but it was really what gave him any backbone.

MR. TOMSKY: He was the administrator.

MR. GREENSTONE: He was successful on some very interesting salvage programs out of England, which is what excited the president and the calling him. Let me tell you something. President Franklin Delano Roosevelt, and maybe nobody even knows, was the Secretary of Navy at one point in time in his political career. He was the guy who came up with the idea of compartmentalizing the *Normandie*. He was the guy who said, "Let's do it this way." Along with him was a Russian, who came into the program and had his own idea about the use of the compartmentalization and/or filling and dumping these compartments in order to right the vessel before raising it. In our business, we used to call it 'par buckling.' This guy had all these ideas. Sullivan had a whole flock of people helping him to come up with different designs and philosophies on how to salvage the vessel. The Russian and the President of the United States were the two most effective people in providing him information on the systems he used to go about salvaging the *Normandie*.

INTERVIEWER: Well, you know, when he was the Secretary of the Navy, he dreamt of this naval facility way out in the country in Bethesda, Maryland.

MR. TOMSKY: But then, when the war started and the Navy realized they had a problem in Pearl Harbor, they sent Sullivan because he was the Navy's salvage expert.

MR. GREENSTONE: That's exactly right.

MR. TOMSKY: They didn't have another officer in the Navy with the experience that Sullivan had.

MR. GREENSTONE: Yes.

MR. TOMSKY: He ultimately went to New York and got promoted.

MR. GREENSTONE: You're right.

MR. TOMSKY: The salvage of the *Normandie* was his baby. Ultimately, he got promoted to rear admiral and he did all Navy salvage, worldwide, during World War II.

MR. GREENSTONE: He built more than one school. He had others going, too, because we had guys from Merritt, Chapman, and Scott, like Moynihan and the Italian guy, who moved over from Merritt, Chapman, and Scott. One of them went to the Army and the other went to the Navy. They never went through any other training experiences.

SPEAKER: Sullivan started in Pearl Harbor.

MR. GREENSTONE: No. He started way before Pearl Harbor. He was sent there in salvage because of Pearl Harbor. At the time, they had nobody like him who could to handle that problem.

SPEAKER: Where was he before that?

MR. TOMSKY: He was in BUSHIPS. He was the Navy salvage contract officer with Merritt, Chapman, and Scott for all of the east coast and Atlantic area.

MR. GREENSTONE: I wish I had that historical knowledge. Our trouble is that we don't drink enough because you would know if gave me a chance.

INTERVIEWER: Why did they want to salvage the *Normandie*?

MR. GREENSTONE: Why?

MR. TOMSKY: Because the thing was taking up all of Pier 88. They had the whole harbor screwed up. They had to get it out of there. The easiest way to get it out was to salvage it. They had to get it out of there and pick up the pieces.

INTERVIEWER: Was the troop ship also a predominant issue?

MR. GREENSTONE: No. The troop ship had nothing to do with it.

MR. TOMSKY: The city of New York and New York Harbor had to get that thing out of there one way or another.

MR. GREENSTONE: Yes. The real benefit of Sullivan was when he went in there, he talked about the benefits of getting that ship out of that area, which he said would be a two-year experience. He said, "In two years, we'll spend four million dollars and we'll have this ship out of here. It'll be ready to put airplanes on the deck." It wasn't to be a troop transport with Sullivan. He wanted an aircraft carrier out of it. The people before him were talking about a troop ship.

MR. TOMSKY: The whole purpose was to get it out of there.

MR. GREENSTONE: Yes. They had to get out of there. That docking space was extremely valuable. They needed it not only as a ship. They needed the area to bring other ships in that would get troops out. There was an article that I read when I was a youngster about how many troops would be unable to reach an offensive position in Europe because of the fact that they didn't have that one area to get ships in and out of.

MR. TOMSKY: If a disaster can be a blessing, the *Normandie* was, because they were able to provide the Navy with capable training facilities and send divers. All the ARS's, salvage ships and diving personnel were trained, for the most part, at Pier 88, on the *Normandie*. They manned the ships that went worldwide during the war for salvage purposes.

MR. GREENSTONE: We'll get on to the stories later, and these pictures will verify it. The fact is that probably as many salvage divers who went to that school went out to areas without vessels and traveled where they were sent to clean up harbors. They lived and survived in those areas in order to prepare for vessels to come in.

INTERVIEWER: Well, they assisted the origin and the harbor clearance.

MR. GREENSTONE: You bet. There are some pictures over there.

MR. TOMSKY: The origin of harbor clearance arose from capturing harbors. You captured an island or a harbor. There were scuttled ships and so forth. You had to get them out of there so that

you could clean up the harbor and bring your ships in. Hence, harbor clearance became an essential part. But harbor clearance in the Navy in World War II was not part of Navy salvage, see? There was another entity that they created, and it was under the service forces. They used all kinds of divers, including salvage divers.

MR. GREENSTONE: Yes. We went over there. There were six of us who went over into the MacArthur part of the Navy in New Guinea, for Pete's sake, to clean up a harbor.

MR. TOMSKY: It's a different entity, harbor clearance. Look up Service Squadron Six in the Pacific. They were responsible for the harbor clearance. They had all the dredge equipment in the Pacific. When they got a harbor, they wanted to dredge it to bring deep draft vessels and things in.

INTERVIEWER: We were talking about the reason for salvaging the USS *Normandie*.

MR. GREENSTONE: There were four major slip areas that you could get into.

MR. TOMSKY: You were trying to shift war materials in every space.

MR. GREENSTONE: That's right. You wanted to ship them into an area, like where those ships were, where you could get in trucks and equipment.

SPEAKER: Everything there was...

SPEAKER: An outsider thinking...

MR. GREENSTONE: Pier 92 was turned into a receiving station. You lost Pier 92. That was where we all lived, ate, and the whole bit.

SPEAKER: Yeah.

MR. GREENSTONE: But Pier 92 was useless. They had that old cruiser tied up alongside. Half the guys lived on it, for Pete's sake. If you went to Pier 88, you went to work.

MR. TOMSKY: I forget the name of that.

MR. GREENSTONE: I don't know. Anyway, they had these old ships in there. You couldn't use that dock. If you went past there, you had 90. You had 88 and 86, too.

SPEAKER: You have a picture of the harbor?

MR. GREENSTONE: Yeah, of course I do.

SPEAKER: Where is it? Is it up there?

MR. GREENSTONE: Yes. It's there, in the middle.

SPEAKER: Oh.

MR. TOMSKY: It may be salvaged.

MR. GREENSTONE: Here we go. A place there, and a place here, a place there, a place here.

Then, you've got a minimum kind of storage place over here. But that was really all you had in this thing.

SPEAKER: Where that one ship is, where do you put that one?

MR. TOMSKY: They assigned the ships. They built the ships. They had to have trained personnel to man them.

MR. GREENSTONE: Then the X one was the *Normandie*.

SPEAKER: They were put to good use.

SPEAKER: They were put to good use all over the world.

SPEAKER: During World War II.

SPEAKER: The ships were also used after the war, too.

MR. GREENSTONE: That was 90. There was a big ship. That was 88.

SPEAKER: I got it.

MR. GREENSTONE: The techniques and the equipment that people had took over when Sullivan left. Sullivan was only there a few months, you know?

INTERVIEWER: Is that right?

MR. GREENSTONE: Yes.

SPEAKER: That was a short period.

MR. GREENSTONE: No, no, no. It was a few months. Then, they went out to the rest of the world. We went out to Africa. He traveled around the world, establishing and helping their salvage programs. The guy who took over was Chandler. The guy who worked with Chandler very closely thereafter, if you read my letter, was a guy named Anderson. Anderson became my diving officer. He was a nothing. He was a reservist. I was a reservist, also. But he was a reservist who came into the service with all kinds of decorations because of whatever his activities were out in the free society. He was a nice guy but didn't know his behind from a hole in the ground. He was probably a pretty fair administrator. He was probably in the job because he was an administrator. My envy is the fact that the guys who succeeded in the Navy were administrators. You know, the workers, guys who worked with their hands, did okay. They might have come out with some beneficial successes. But they didn't have the guys who were the thinkers. The guys who were a little bit older, two years older than we were, thought differently from us. We were kids. They succeeded, you know. We just went to work. We did what we were told to do. We were overjoyed when we were successful. We made the most of letting people know how good we were. You know, it was a matter of ego.

INTERVIEWER: Well, one of the things that has always come up about the *Normandie* has been whether it was sabotaged or not.

MR. GREENSTONE: Oh, that's nonsense. After all the stuff I saw on that ship, I don't believe there was any sabotage. If there was ever any sabotage on that vessel, it was done by the mayor of New York.

SPEAKER: Wasn't the ship in a fire? When they tried to put it out, the water shifted?

MR. GREENSTONE: They didn't just try to put it out. They had vessels on the beach shooting water on that thing. They had vessels on the dock shooting water on that thing. They had fire vehicles on the highway shooting water on that thing. Nobody ever took the time to go down and close the portholes in the E and D decks. As this thing started to come around from all of the water they were pouring on it, the water started pouring into the portholes.

SPEAKER: But it was sabotage?

MR. GREENSTONE: Huh? No. It wasn't sabotage. It was stupidity.

INTERVIEWER: Well, was the fire started by electric spark?

MR. GREENSTONE: The fire wasn't started by electrical spark.

MR. TOMSKY: It was a welding spark.

MR. GREENSTONE: It was a welding spark, yeah.

MR. TOMSKY: The firefighters who fought that fire didn't know what they were doing.

MR. GREENSTONE: Yes.

MR. TOMSKY: They capsized the vessel.

INTERVIEWER: They did that by pouring all this water in?

SPEAKER: Exactly.

MR. TOMSKY: But who the heck had experience in fighting those kind of fires?

MR. GREENSTONE: Did you ever see the room that the fire started in?

INTERVIEWER: No.

MR. GREENSTONE: Well, I'll show you the room that it started in if I can get through all this stuff. This is a beautiful room. Hold on, Arthur. Look at this magnificent room. I wish I had better light. That's the room that it all started in, right there. It all started in their attempts to cut these

lights out. That's the room. This stuff has been up here waiting for you, as a matter of fact. I wouldn't believe the money that I've spent cleaning up this room and getting my diving history out of this room. Now, I'm putting these pictures back up because Jim said, "Len, if you have any pictures, put them up because pictures do best for our purposes."

MR TOMSKY: What the heck does he know?

SPEAKER: I agree.

MR. TOMSKY: That's right. What the heck does he know?

MR. GREENSTONE: Well, the thing is that when you love a guy, sometimes, you'll believe anything he says.

MR. TOMSKY: Oh, God Almighty. You don't believe what I tell you. You told me that you loved me, but you don't believe what I tell you.

MR. GREENSTONE: The heck I don't. I believe everything you tell me.

SPEAKER: Oh, the rumor got out on you.

INTERVIEWER: What happened to the *Normandie* after they floated it?

SPEAKER: They put it into commission as a troop ship.

INTERVIEWER: How many years did she serve as a troop ship?

MR. GREENSTONE: She never served as a troop ship.

SPEAKER: Wasn't she the USS *Lafayette*?

MR. GREENSTONE: No, no, no. They moved her to Elizabeth, New Jersey. From there, they took her to the...

SPEAKER: Well, where's the *Lafayette*?

MR. GREENSTONE: They renamed her the '*Lafayette*' while they were in the process of reviving her.

SPEAKER: They never commissioned her as the USS *Lafayette*?

MR. GREENSTONE: No. She never went to work. In fact, they sold her off to the men of a steel company. They chopped her all up. As a matter of fact, I've got a picture of the last piece of her hull that they brought up, the keel. It was 520 tons or some crazy thing. I don't know. It was a massive piece of steel, the last piece they brought off of the bottom after they chopped her up.

SPEAKER: Why did they change and rename the ship?

MR. GREENSTONE: Oh, when she caught fire, the U.S. bought the ship from France. The *Normandie* became the USS *LaFayette*. It was going to be converted. As Jack said, it was going to be converted into a troop transport, which was their first thought. The work was being done at the time to convert her for a troop transport. The fire changed the whole plan. Then they decided that by the time they got through gutting her, taking off all of her superstructure...did you see the pictures of what she looked like, starting with what she looked like by the time they cut the superstructure off?

SPEAKER: Yes.

MR. GREENSTONE: I'll tell you what. She was a natural for an aircraft carrier. She would have been the beamiest and biggest aircraft carrier we would've had at that time. She was so screwed up.

INTERVIEWER: You're telling, I think, that we bought the ship from the French.

MR. GREENSTONE: Yes.

INTERVIEWER: One story that has been circulating for years is that the Vichy government...

MR. GREENSTONE: Those stories are one and the same, but I'll tell you what. The United States government paid France for that ship. I've got a copy of the transfer document that was sent to me. If only I could find it. There was a group that worked in *Normandie*. Do you remember the guy who came to our reunion, to which you came, and he spoke? He was the president of the

Normandie club. You were there. Remember, Jim, when we used your facility, and I think it was the first reunion we had in San Pedro. The guy came out and brought us the formal purchase agreement and transfer of the *Normandie* to the United States. It showed exactly what was paid for it. What you are saying is true in the fact that the money was never transferred or paid until the war ended.

MR. TOMSKY: Well, it was probably the French government in exile then. It was in Britain at the time.

MR. GREENSTONE: That is probably true, yeah. They just didn't pay for it until after the war was over.

MR. TOMSKY: I don't think they did business with Vichy.

SPEAKER: Well, it was probably the French government.

SPEAKER: It was in New York Harbor, and they were refitting it at the time?

MR. GREENSTONE: They were refitting it and planning to make a troop transport out of it.

INTERVIEWER: But it had sailed then in December, was it?

MR. GREENSTONE: She had sailed in December. I believe it was January 9th that she caught fire. It wasn't until the 15th of January that they were able to control the fire, and the ship rolled over. It might've been the 12th. I don't know.

INTERVIEWER: At that time, the ship was in the ownership of the U.S. Navy.

SPEAKER: Government.

MR. TOMSKY: I suspect so.

MR. GREENSTONE: I'm sorry. What was the comment, again?

INTERVIEWER: My understanding is that in December of 1942, it sailed in and was commandeered by the U.S. Government.

MR. GREENSTONE: That's right. It did not belong to them. They just took charge of it. They took control of it with the intent to use the vessel without buying it or paying for it until it caught fire. Then, they changed the name to the *Lafayette* and arranged to buy it from the French government.

MR. TOMSKY: But they were converting it.

MR. GREENSTONE: They were converting it at the time.

MR. TOMSKY: Bought it at the time U.S. Government had –

INTERVIEWER: It caught fire after the Navy started converting it.

MR. GREENSTONE: That was exactly what set it on fire, yeah. The Navy used to talk about the fact that the commercial company that was working on it was totally out of its realm of knowledge because they really messed up everything on that ship. The fire got started because they had very poor security.

SPEAKER: Well, it was an accident.

MR. GREENSTONE: Huh?

SPEAKER: It was an accident.

MR. GREENSTONE: Merritt, Chapman and Scott, even though they continued on and had a very major part in the salvage of the *Normandie*, there were a lot of people in the Navy, and I have to say this on tape so that I won't be sued, talking about how the problem was developed by them. They caused the problem. They had lousy security. The people who were working on the ship were people they brought in from anywhere and everywhere, and they didn't know who the heck they were. As a matter of fact, the hoses that they had on the ship, the hoses they brought on in case of a fire, wouldn't fit the fittings on the ship. They couldn't even connect the hoses to put the fire out. That was a lousy group in administrative authority.

MR. TOMSKY: But there's not a ship that goes through a major overhaul --. Well, of course, you know that it's going to happen, so you worry about damage control.

MR. GREENSTONE: That's right, and they didn't have it. That was the problem.

MR. TOMSKY: Having a fire was not unusual in the facilities to put the fire out.

MR. GREENSTONE: Bless your heart, Jack.

MR. TOMSKY: Their screw up was the fact that there was no way to put the fire out.

MR. GREENSTONE: They lost control.

MR. TOMSKY: You know the whole story. Even in the shipyard, you've got a guy standing there if you're going to burn the thing out. The guy has to stand there with a CO<sub>2</sub> container.

SPEAKER: Back up some. Was the ship just floating at sea when they went out there and commandeered the thing?

MR. GREENSTONE: No, no, no. It came into the harbor.

MR. TOMSKY: It steamed into the harbor.

SPEAKER: It came into the harbor.

MR. GREENSTONE: You bet. It came into the harbor. The crowd met it. Then, she pulled in there and they tied up her up. It was a great, great thing for the city of New York.

INTERVIEWER: All the passengers got off to these tumultuous crowds.

SPEAKER: Yes.

SPEAKER: Yes. It was a liner.

MR. TOMSKY: It happened, but I don't know if that is the history that you're looking for.

MR. GREENSTONE: Yes, but I think we were going off track. Let's get on to the diving program that came from it, I hope.

MR. TOMSKY: The diving program that came from it, right.

MR. GREENSTONE: I think the thing that was important is the fact that there was so much structural work done on that ship. If it had been done before, I wasn't aware of it. I was only a kid, anyway. But I later read and learned that there wasn't much of it. The kinds of bulkheads that were built to divide the ship, to compartmentalize the ship, were really somewhat unusual. They used the massive timbers with two by four interlocking timbers and created a bulkhead by establishing a steel frame and putting this one major piece of timber on top. Then, divers would take two by fours, simple two by fours, and bring them down and put them up into the groove. Then, two divers would dive down with another piece, move it under that, move it up and lock it. But you have to remember that this sounds like a very simple thing to do. They were taking a piece of eight by twelve timber and could not see the other diver or what he was doing. He could only adjust where that timber was going by his feel. Too often, there was one guy down and the other guy got all the slivers in him, that piece of timber took off for the top. They had to control that.

SPEAKER: Were they using weights or something?

MR. GREENSTONE: They were using just their bodies and shifting their weight. You dump your weights and send the weight down by your weight.

MR. TOMSKY: They needed to focus on the salvage of the *Normandie*. At that time, it was probably the greatest capsized ship in history, and they were able to right it and float it.

MR. GREENSTONE: There were a lot of people who said it would never happen.

MR. TOMSKY: Well, be that as it may, it happened. It was probably the most successful marine salvage operation ever.

SPEAKER: Is there anything that comes to your mind? I mean something that is well known or techniques.

MR. TOMSKY: No, no. The things were designed to fit the particular problem.

MR. GREENSTONE: You're on an excellent point. There's a comment in this book I read that caused me to laugh because I had to put my mind back to what the heck they were talking about. The ship was up in September. "Greenstone stood in awe, looking at the patches he put on the vessel." Do you remember that bit I was telling you about? It was an unusual situation because of the 300 or 350 patches that were put on the vessel, there were something between six and eight locations in the forward part of the mid-ship of that vessel. That was because of the damage inside the vessel, along with the fact they used to have a walkway that ran alongside the vessel when they were in the process of converting it. When the vessel capsized, that walkway got all busted up. Some of the timbers of the walkway went into the portholes. The guys inside, not being able to totally get to it, had to send divers to the outside to go into the mud to put those things in. The tooker patch was designed to go from inside the vessel to outside, with the strong back and wing nuts, close against the outside of the vessel. Now, you can't do that. What you had to do was go down, and some of the portholes were beyond sinking depth. Sinking depth ran anywhere from six to eight feet in mud and then depressed. If you wanted to go further than that, you had to wash yourself in there. You washed yourself down to the porthole. Then, the first thing you did so you that you didn't screw up was lock in a device that let you know where that porthole was so that you didn't have to spend a lot of time finding the thing again. Then, went go back the next time, you felt around and tried to find out about that port hole, which opened up on the inside of the vessel. That had to be done away with. You had to get it out of there because you were going to put the patch on from the outside. You had to use tools, pneumatic tools, to chop off the hinges and junk from the inside and stuff the junk in, take a saw and cut the timbers off, shove the timbers in to pull timbers away, and then, take the tooker patch and put it inside. You didn't have much of a lift on some parts of the inside of that opening, where you could adjust this patch when you put the strong

back on. The rubber was going to be able to lock from the inside. Then, you locked them down. I was telling Jack earlier of one of the experiences that was probably the most existing of all to me. One of the dumbest things that made me laugh while I was in the mud was that I was holding one of the wing nuts and the patch, trying to put the other one on, and I dropped the ring nut. In the water, you did not go reaching for it. You got your hand out of the way and went down below to where you thought it was, in approximation, and started shaking the mud. The ring nut would come down through the mud in your hand. Then, you took it and put it on again. But when you got it done and got the ring nut on, you stopped. But you were a kid, and that happened. You were a mechanic. You happened to be a mechanic anyway. You couldn't help but laugh because you had never ever touched, witnessed, or involved yourself in a thing like that before.

MR. TOMSKY: For your edification ----.

MR. TOMSKY: No, but if you think about it, you know what a boiler is.

SPEAKER: Yes.

MR. TOMSKY: You know what the manhole plate in the boiler is?

SPEAKER: Yes.

MR. TOMSKY: You put the manhole plate inside. Then, there's a bar that goes across.

SPEAKER: Yes.

SPEAKER: Well, that's what --.

MR. TOMSKY: That's exactly right.

INTERVIEWER: Captain Tucker was on the *Normandie*. Was he brought in because of his mechanical background?

MR. GREENSTONE: With Scott for 22 years.

MR. TOMSKY: Yes.

MR. GREENSTONE: He was a full-fledged mechanic. He wasn't a jerk. Let me tell you something. He was a full-fledged diver, you know. Being a mechanic and a diver, as he was, which was what Jack was explaining, was an unusual thing in the diving industry at that time. They were trying to take us mechanics and teach us to become divers. Contrary to the Navy's previous activities, you took divers and taught them to become mechanics. They were taking mechanics and trying to teach them to become divers.

MR. TOMSKY: Let me give you an analogy about welding in the oil patch. We found that to take a diver and teach him how to weld just didn't work. But we could take a welder and teach him how to dive.

MR. GREENSTONE: You bet.

MR. TOMSKY: It worked.

MR. GREENSTONE: Yes.

MR. TOMSKY: It was same thing with a mechanic.

SPEAKER: It was same thing with a mechanic.

MR. GREENSTONE: You're exactly right. When you talk about the bulkheads that they had to build --.

INTERVIEWER: We worked the other way around. We trained Ken Conda to be a researcher.

MR. TOMSKY: Ken Conda was an exception. He was a good man.

MR. GREENSTONE: Let me tell you something. You know something?

MR. TOMSKY: I was saddened by his death.

MR. GREENSTONE: I'll tell you, it sits in my heart. He was one of my dearest, dearest friends.

INTERVIEWER: Hardly...

MR. TOMSKY: Kenny Conda was a heck of a guy.

MR. GREENSTONE: I don't even know that you really know how great a guy he was.

MR. TOMSKY: Oh, I knew him well.

MR. GREENSTONE: I'm sure you did, but I had a very, very close relationship with Kenny.

MR. TOMSKY: Was that after he left the Navy?

MR. GREENSTONE: It was when he worked for Art, as a matter of fact. I knew Ken before that.

I met him at Art's, and our attraction, boy...

MR. TOMSKY: I spent four hours with that silly guy.

MR. GREENSTONE: Please don't say that.

MR. TOMSKY: Don't you go to work for these people. You've only got 18 years in the Navy.

MR. GREENSTONE: You believe that...

MR. TOMSKY: Now, you have two more years until you retire.

MR. GREENSTONE: Yes.

MR. TOMSKY: I think he had 18 years then. Stay here and retire.

SPEAKER: But he loved...

MR. TOMSKY: I'll make sure you're a chief when you retire. He wouldn't do it. He's going to Art and the program. He was a heck of a guy, a good man. I wanted to keep him in the worst way.

INTERVIEWER: We were really close friends.

MR. GREENSTONE: Yeah, I know you were.

INTERVIEWER: I wanted to keep him in the worst way, but people get their minds set --.

MR. GREENSTONE: When they started drawing in all the water, and I think it was in late July or early August when they were getting ready, they sent divers down. They were giving directions for what they were supposed to be looking for and all that kind of stuff. The book says that to get on the *Normandie*, it took about 58-foot cranks. That was not really true, you know. In a 40, 50 or 58-

foot area, there were some cracks. There were no cracks 58 feet long. That was why they took some of the cracks and used a newly designed kind of a tooker patch to go in there. It didn't work, by the way. They put it in there and it helped a little bit, but not a lot. The real asset, of course, was going in there and jamming bags of rags in, which they did. I guess for the next five or six days, they were in there on an almost continuous basis, night and day, jamming rags in the cracks. Of course, they were also taking down bags of sawdust that they could dump off. I don't know if you understand how it functions, but sawdust, when you dump it off, wherever the water is traveling, it is supposed to follow. Then, when it gets in there, it expands. But the divers couldn't see what they were doing. They dumped the bags. Three quarters of the sawdust was on the surface, going where it was not supposed to go. That's not a fair thing to say because some of it got in there.

SPEAKER: It just didn't work.

MR. TOMSKY: How did they right the *Normandie*?

MR. GREENSTONE: Well, they ultimately righted it by filling it with concrete. They probably put in almost 300 yards of concrete, 80 in, 80 in. They kept filling the double bottom. They kept filling the vessel with concrete, which was the thing that ultimately slowed down the seepage.

# UNDERSEA & HYPERBARIC MEDICAL SOCIETY

## ORAL HISTORY INTERVIEW

CAPTAIN JOHN HUNTLY BOYD, JR., USN (Ret)

Washington, D.C.

Monday, November 24, 2003

## PROCEEDINGS

INTERVIEWER: Captain Boyd, when were you born?

CAPT. BOYD: I was born in 1931.

INTERVIEWER: Where did you go to school?

CAPT. BOYD: Well, I grew up in Trenton, Michigan, and went to Trenton High School. Then, I went to the Naval Academy and graduated in 1953.

INTERVIEWER: What influenced you into coming into the Navy?

CAPT. BOYD: Well, I grew up close to the Detroit River right at the head of Lake Erie, so I was on the river the lake all the time. It just seemed like the natural thing to do.

INTERVIEWER: How did you first get involved or get interested in diving?

CAPT. BOYD: When I graduated from the Naval Academy, I served on two destroyers and went to submarine school. They decided I was colorblind, so they punished me by making me an engineering duty officer and sending me to the Massachusetts Institute of Technology (MIT) for a graduate degree in naval architecture and marine engineering. There were 16 naval officers in the class. About a third went to the nuclear program and went right to work for Rickover. Another third went into submarines. They got their basic submarine training and served in the submarines for a year before their first engineering duty tours, and the rest of us were all sent to diving school. There was no choice, but I was delighted with it.

INTERVIEWER: You've been affiliated with Navy diving over the years. Can you, from diving school on, talk about your Navy diving career, its past, present, and future?

CAPT. BOYD: Since I was an Engineering Duty Officer (ED), the EDs wanted to have a sprinkling of diving-qualified officers who would be sprinkled around the world with some basic salvage training and would be available for any needs that might come up. After I got out of diving

school, I went to Long Beach Naval Shipyard. Although I was the shipyard diving officer, it didn't place any demands on me.

I went from there to Guam, again as a diving officer and an assistant repair officer. When I was there about a year they had a typhoon, Typhoon Karen, that caused havoc in the harbor at Guam. Eleven ships and craft were sunk or stranded and I got started really quickly in salvage.

The Seventh Fleet sent their salvage officer, Commander Tom Blockwick, down after we had already gotten started in getting some of the more valuable assets re-floated, in particular a floating crane, and they sent in two salvage ships, ARSs.

But Blockwick had an ulterior motive. He let me do everything. He watched over my shoulder. His ulterior motive was that he had been over toured as a Seventh Fleet salvage officer. Tom was really the last of the World War II trained ED salvors who was not too senior to participate in diving and salvage or hadn't already retired. They couldn't find a relief for him. He saw this young lieutenant commander, who was nine years junior to him. He was doing well at salvage and seemed to like it. He had, in the back of his mind, "There's my relief."

About six months later, they had another typhoon. It wasn't as bad as Typhoon Karen. Typhoon Karen, incidentally, was a big typhoon. It had 150-knot steady winds with 180-knot gusts. That was 207-mile per hour winds. It was quite an experience. The new typhoon blew only a hundred knots or so, but it just sat on top of the island for a long time and six more ships and craft were sunk, including one up in Saipan. That time, Blockwick didn't even come down. He just said, "You've got a qualified guy there. Go ahead and do it."

They sent another ARS to help us. Of course, we had the advantage of having a ship repair facility there with the industrial facilities and everything. I had a diving locker of about five guys, but it was great to have a Navy salvage ship with a good store of knowledge, equipment and divers.

Well, as time went on, I did relieve Blockwick. We were stationed on a repair ship, the USS *Ajax*, which was home-ported in Sasebo, Japan, and I relieved him in April of 1964.

In May of 1964, the USNS *Card*, a small carrier that used to ferry aircraft to Vietnam, was mined alongside the pier in Saigon, so off I went to Saigon. It turned out that when it happened, Blockwick was absolutely incommunicado on a train between Sasebo and Tokyo, so he was just unavailable to be brought back. I was on my own.

We patched up the *Card*, pumped it out and towed it out. It took about three weeks. I remember that the day we took it out was Ho Chi Minh's birthday. It was in May of 1964. There was betting in the bars in Saigon that we would never get it out of the river. As a matter of fact, we ran aground at one place, under tow, of course, at one sharp corner in the turn in the river. Fortunately, the tide was rising and we got it off, continued on and took the ship to Subic Bay, Phillipines.

Not long after, of course, Tonkin Gulf occurred. We were actually on another salvage job in the Philippines at the time, and for the rest of my tour there, I was on the go all the time. They were activating all kinds of ships. The crews weren't too experienced. The skippers and the chief mates were okay but they had a total dearth of qualified second mates. Second mates were the guys who did the navigating because they had the morning and evening watches. Those were the guys who were running the ships aground. I did three or four commercial ships that ran aground in the South China Sea or in Vietnam. They all happened when the second mate had the deck.

During that time, the destroyer USS *Frank Knox* ran aground on Pratas Reef. It's a small, uninhabited atoll in the South China Sea. That was the first time we ever used cast-in-place foam on a ship. It was five weeks and we rode out three near misses from typhoons and again, that was exciting. The ship was bouncing around and the typhoon was approaching. The waves were

knocking the heck out of the ship. I remember we had to be careful to not go step out on the open bridge, because the radar antennas above looked like they were going to be shaken right off the mast. Service Group 3/CTF-73 was the logistics manager for the Seventh Fleet. I was their salvage officer. I was the Seventh Fleet salvage officer.

From there, I went to service force commander in Norfolk, Virginia. Again, the service force was a logistics agent for the Atlantic Fleet and as such, I was the Atlantic Fleet salvage officer. I did three significant salvage jobs there. At that point, I had done thirty salvage jobs. Incidentally, I loved to dive and was a good diver, but diving, to me, was the entree into salvage, which is the really fun part and the reason for being. Divers have to do something. There has to be some reason for them. In my case, it was salvage. I had done thirty salvage jobs and only one of them was unsuccessful. That was the USS *Bache*, a destroyer, which had been blown aground during a storm in Rhodes, Greece. They dragged anchor. They were doing some machinery repairs and dragged anchor. They didn't have steam up. One of those siroccos, those strong winds in the Mediterranean, came up. It was predicted. There was no surprise, but they either couldn't or didn't think about steaming to their anchor, and the anchors dragged. They ended up on the beach right at the entrance of the Old Harbor of Rhodes.

If you've ever been to Rhodes, you'd recognize the harbor is manmade with a very narrow entrance. That was where the Colossus of Rhodes was. It was a lighthouse that strode across this narrow entrance of the Old Harbor. One of the wags we had over there at the time said they had just made a startling discovery. The Colossus of Rhodes had big, gray feet, and one of them, the left foot, was the former USS *Bache*. Another storm came along and just wiped the bottom out of the ship. We were unable to get aboard it for several days. When we got back aboard it, you heard a lot of creaking and groaning. You looked down in the fire room and the boiler was moving around.

Somebody said, "Look at this. What's going on here?" I said, "the boiler is not moving around. It's the ship moving around. The boiler is stationary." In fact, that was one of many cases in which my diving experience and ability proved valuable to my salvage officer duties. I did inspect it myself and found that the entire bottom of the ship, through the entire engineering section, was totally separated from the rest of the ship. Salvaging it was out of the question and a Navy contractor ultimately broke up the ship.

After the CINCLANTFLT salvage job, I went to the Experimental Diving Unit (EDU) in Washington, D.C. It was in Washington in those days. The thrust in those days was saturation diving. We were very, very busy doing saturation diving tables. We were doing 1,000-foot, 30-day long dives routinely as they developed the saturation tables. That was interesting.

I was made the project officer for the acceptance of the first deep diving system, the Mark I deep diving system, and we did our trials off San Clemente Island in California from a contract salvage ship. It was a civilian-manned Navy salvage ship that was under contract to the Supervisor of Salvage (SUPSALV). We did, in fact, complete the series of dives. The requirement was only to go to 850 feet and that was what we did, although the system was good for 1,000 feet.

From EDU, I went to the Bureau of Navy Personnel (BUPERS). I was the detailer for the engineering duty officers. I always said that at least two of the jobs that I got as a commander were way ahead of time for my seniority because of the diving and salvage capability.

On the Seventh Fleet job, as I said, I relieved a fellow who was nine years senior to me, and when I went to SERFLANT, I relieved a fellow who was about seven years senior to me. The salvage side of my assignment always got the notoriety, but I still considered myself a mainline Engineering Duty Officer. Although I could have gone to the Supervisor of Salvage's Office, I was interested in breaking the chain to demonstrate that I was interested in doing something else.

When the BUPERS job came along, I accepted that and of course, there was nothing to do with salvage and diving in that job except detailing some of the guys and some of the ED divers. When it came time to leave there, I had myself slated to go to the Boston Naval Shipyard as one of the second tier officers, a planning officer or production officer.

Another fellow who was a couple of years senior to me came to me and said, “Huntly, I’ve thrown my hat in for the SUPSALV job and I wanted you to know.” He did that, I think, because he knew that had I wanted it, I could have had it because of all my experience. He had much less experience. He had had the Seventh Fleet salvage job and had done a couple of salvage jobs, but nobody around had the amount of experience I had. I said, “Oh, fine. I’m going to a shipyard.” Well, this fellow was a very fine guy and a great friend. It turned out that some captain, who was a design-type guy in the engineering duty community, retired early, unexpectedly, and this other gent who was looking for the SUPSALV job turned out to be the only person who had the background and qualifications to take the design job. The powers that be said, “Well, the only person we can send over to SUPSALV is Boyd.” I always characterize it as, ‘Don’t throw me in the briar patch.’

When I was SUPSALV, one of the interesting and challenging things that went on was the transfer of the EDU from the Washington Navy Yard to Panama City, Florida. There were a lot of politically sensitive issues about it. In a nutshell, the folks in Panama City, at the laboratory, had convinced the Navy, through their favorite Congressman, to build an ‘ocean simulator,’ as they called it. It was just a massive hyperbaric facility in a spectacular place.

In the meantime, the existing Experimental Diving Unit was getting down at the heels. It was built in 1938 or 1939 and although the chambers were suitable for 1,000 foot dives, that was all. They were also relatively small. Here was this great, big beautiful place down in Panama City that was just beckoning a bunch of divers. The laboratory had the place built with military

construction funds but didn't have anything in the budget for people to man it. In my view, they figured, "Well, the way we're going to man this outfit is by making a run on the Experimental Diving Unit and get the EDU to come here and they'll work for us and man the ocean simulator."

Well, that ended up in a political tug of war between SUPSALV and the laboratory in Panama City as to who was going to be in charge of the Experimental Diving Unit. The Naval Sea Systems Command (NAVSEA) was sending the divers, the technique and the technical expertise. The laboratory thought, "They're just coming down to run our facility." You can just see the problem there. They sent a guy named Jack Ringleberg to be the Assistant Officer in Charge of the Experimental Diving Unit. He ran the operation in Panama City and got it going.

The commanding officer of the Experimental Diving Unit remained in Washington because they were still doing work there. Jack, I'm sure, has told you or will tell you all the travails that he had, that he had a terrific job of being the diplomat between the divers and the laboratory people. It was also complicated because the construction of the system supporting the hyperbaric facility was not documented properly, so much of the mechanical system and all the air and gas systems instrumentation had to be redone because proper documentation was not maintained. At the moment, I can't remember who paid for it. It seems to me that NAVSEA paid for it, but that was another thorn between the laboratory and NAVSEA. At any rate, the Experimental Diving Unit did ultimately get transferred and abandoned the old Washington Navy Yard facility, which was shared by the Navy Diving School, both of which are gone now. It's a parking lot.

Somewhat later, incidentally, the diving school also moved to Panama City. As an anecdote on that, I think it was in the winter of 1981 when the Air Florida plane crashed on takeoff from National Airport into the 14th Street Bridge. There were a hundred or so people on board. It was going to Florida. There were a lot of survivors and a lot of people were rescued. But after the

immediate rescue, there were many, many more people who drowned. Many of them were still in the wreckage. Others were floating down the river. They mobilized divers to do this operation.. It wasn't a rescue. It was a body recovery, actually. It wasn't a fun job.

The weather was terrible. It was in the low unit numbers, zero degrees Fahrenheit. Remember, I said that the diving school had moved down to Panama City, where the water was nice, clear and not too cold. It didn't have the opaque water of the Washington Navy Yard and the bottom mud in which to dive. I was convinced that the Navy divers, who had been trained at Panama City, would quit as soon as they got to Washington and tried to make their first dive in the Potomac River, which was full of ice and zero degree temperatures. To their credit, though, I understand not a single one quit, so I was wrong on that one.

Anyway, let me get back to SUPSALV. The big thing at SUPSALV for me was the Suez Canal clearance. We also did a number of aircraft search and recoveries that were successful. One of them was for an F-14 that fell off a carrier up in the North Sea. We found that and recovered it. In about 1994, there was a C-5A coming out of Saigon, full of orphans, and the rear door fell off or blew out. I think they lost a few of the orphans. Most of them were okay. The plane flew back to Saigon, but they needed to get this rear door ramp to see what happened, what went wrong, so our guys went out, found that and recovered it.

The most lasting achievement while I was at SUPSALV was probably the real development and expansion of the underwater search and recovery capabilities. While I was there, we built the first deep drone, which was fairly cheap. It wasn't very good for searching because it wasn't very mobile, but it was a good inspection and minor work platform. They're still using the deep drone. Probably the only thing left on it is one bolt from the original one because they could fund its upgrading from one pot of money, not new procurement money. They've managed to keep the deep

drone in existence by continued upgrades for 30 years. They could probably find one bolt or one nut left on the current one that was on the original.

But as I started to say, the big thing while I was SUPSALV was the Suez Canal clearance. In 1968, the Israeli-Egyptian War took place and the Israelis were coming so quickly across the Sinai that the Egyptians were afraid they would overrun the Suez Canal, so the Egyptians scuttled ten ships, tugs and dredges in the canal, to prevent their use. The war ended fairly quickly, with the Israelis and the Egyptians facing each other across the canal, which had a bunch of wrecks in the middle of it. In the 1973 war, the Egyptians did pretty well for the first time. They regained their pride. They beat the Israelis badly in the beginning, but as time went on, the Israelis got their act together and crossed the canal before a truce was established.

In January or February 1974, I got a call from our Navy salvage contractor, Peter Barraca of Murphy Pacific. They had been nosing around Cairo, trying to get a contract to clear the canal. All of the tealeaves said that the contract was already settled with a Dutch consortium led by Smit. Barraca wasn't getting much attention until he happened to mention that they had access to the Navy heavy lift ships, which were the former German heavy lift ships that had been used in the 1956 clearance of the canal. That got the attention of the people in Suez.

I have no way of knowing, but you can just guess that the Egyptians probably started thinking, "Well, these guys are real. They can get these wonderful salvage ships," which were indispensable in the 1956 clearance. They probably thought, "If it's a United States contractor who happens to be the U.S. Navy's contractor, maybe we'll get the U.S. to somehow fund this operation." They finally responded to Barraca and said, "Yes, let's talk." Late on a Friday afternoon, probably around 4:30, Barraca called me and said, "I have to have an answer. Can we lease the heavy lift ships from you?" I said, "This is a pretty politically charged decision. I can't

make it at my pay level, so I'll call you back." I ran up to the commander of NAVSEA, Vice Admiral Bob Gooding, who was a great guy, and we sat down and talked about it. I had pictures of the heavy lift ships and told him what was happening. It was, as I said, probably late in the afternoon on a Friday. It was probably 5:30 by that time. There was nobody around. He said, "We'll both probably go to jail for this, but I like it. Go ahead, on my authority. Tell Barraca he can lease the lift ships for terms to be determined."

Things were quiet for a while even though Bob Barraca told us that they pretty much had the contract in hand. I believe this was because the Egyptians began to fear unexploded ordnance. Around April, if you remember, Mr. Kissinger was tromping around the Middle East and doing a good job of mending fences between the Israelis and Egyptians. He was, no doubt, making all kinds of offers and promises to the Egyptians, that the U.S. will help rebuild your economy, your infrastructure or whatever. Sometime in April, a message came the U.S. interests office. There was no ambassador, but they had an ambassador-level guy there. He said that the Egyptians had asked for the assistance of the United States in clearing mines from the waterways and on land and a number of other things, like training their people and things like that. Tucked in at the very bottom was, "and to assist us and to fund for the clearing of the Suez Canal." Well, that got attention at the Pentagon. I had to get on my horse to go tell people what it meant, how it happened, and that no, I didn't make it happen.

I remember that Admiral Zumwalt wrote a note on something and said, "I understand there are low-level people from NAVSEA who are making commitments to the Egyptians to clear the Suez Canal." Fortunately, Admiral Kidd who was the Chief of Naval Material (CNM), at the time, was a great sponsor of mine. He loved divers and loved me. He had been counseling me all along that if anything happened and it looked like they were going to get involved, to go over and see

Vice Admiral Cousins. He was the plans and program guy and the political-type guy on the OPNAV staff. When those things started happening, I went to see Admiral Kidd. He was on travel. Remembering Admiral Cousins, I went over to see Admiral Cousins with my deputy, Captain Bob Moss, and a big picture of the two lift ships working in the Saigon River.

INTERVIEWER: Was that the Mekong River?

CAPT. BOYD: It was the Mekong River, right. I quickly got through the outer office to Admiral Cousins. He said, "Well, this is interesting." He supported me and went in to see Admiral Zumwalt, who was the Chief of Naval Operations (CNO). From there, things were quiet for a few days. Anyway, I had been sending memos and copies of messages over to OPNAV all along, but apparently, nobody was paying attention to them. It shouldn't have been a surprise that we also got asked to fund the Suez Canal clearance.

A few days later, I got a call from the Assistant Secretary of the Navy for Installation and Logistics to come over to his Crystal City office and tell them about the Suez Canal clearance. I went over to see him, and he soon looked at his watch, saying, "I've got to go over and see Navy Secretary Bill Middendorf. Well, why don't you come along with me?" he said. We went over to the Pentagon and he went in to see Secretary Middendorf with my picture of the lift craft. I was waiting in the outer office. It wasn't two minutes before the secretary came out and said, "Come on in." He had run aground immediately, so I had to explain to Middendorf what was going on. It went on for a few minutes. Middendorf was a businessperson. He checked the Dunn & Bradstreet on Murphy Pacific, running a couple of numbers, and decided, "Yes, they're a small company, but they can probably do it."

At that time, it still seemed as though we might have to fund the operation and loan the lift ships through Murphy Pacific. Middendorf looked at his watch and said, "Oh, we've got to go and

see Bill Clements.” who was the Deputy Secretary of Defense. Mr. Clements came out of the offshore oil industry and heavy construction work, so he knew what was going on. He knew heavy equipment. He said, “Well, you had better come along, Captain.” so I tagged along and they raced over to Secretary Clements' office. Again, I was waiting on the outside. Two minutes later, I was called in. Clements was very skeptical. I was explaining what was going on, what could be done, and how much it might cost. The reason he was skeptical was because Murphy Pacific was planning on subcontracting to a German firm for two salvage cranes, 500-ton cranes, which could actually pick up 1,000 tons each in one mode. Clements was familiar with heavy cranes and their costs. In those days, 1974, one of the big, heavy cranes that they used in the offshore oil industry that had a 500 or 600-ton capacity probably cost \$25,000 a day and the German heavy lift cranes were going to cost about \$8,000 each a day. That was one of the reasons he was skeptical. He just couldn't understand how we could do that. That was all going on and at one point in time, Clements looked up and there was his aide, Captain Kenny Carr, who later became a Vice Admiral and COMSUBLANT, who was his naval aide and was looking over the table where we were all huddled. We had a map that showed generally where and what the wrecks were. He looked up and there were a lot of people around the table. Secretary looked around and said, “What are all you people doing here?” Carr said, “Mr. Secretary, this is the most interesting thing that's gone on here in a month!”

Anyway, I heard later that Clements said it was going to be a technical and financial disaster, but he couldn't turn it off. Sometime later, maybe two or three days later, I was called back over to OPNAV and was asked how could we do it. Well, the Navy could do it using the same equipment and contractors or with fleet resource. Of course, we could also just pour in money. That's a bad idea, to just pour money into the project. I always described it as a three-cornered hat.

Murphy Pacific would be doing the work. They would be whispering all the time to the Egyptians, “We can do this more quickly” or “We can do it more safely if we get more facilities and more equipment and more people.” Of course, the Egyptians would agree. The price would be going up and up and there would be the poor Navy, paying the bill for these two, each whose motivation would be to make it more and more expensive.

I remember I was called over to OPNAV on a Saturday. I went to the morning briefing of the Secretary of Defense and the Deputy Secretary and all of the chiefs of the services. They called it the ‘tank.’ I wasn’t taken into the tank. I stood on the outside. They finally came out and said, “Huntly, there is no decision yet on whether we’re going to do it totally with Navy resources or using contractors.”

A couple of days later, I was called back again and told sit down. It was after lunch. I would say that it was maybe two in the afternoon. They said to me, “You have the rest of the day, before close of business, to prepare two plans. Come up with one plan to clear the canal using naval resources and one to do it with civilian resources, or Navy contractors. Oh, incidentally, whichever way it goes, you’re going to be in charge.” I had no axes to grind. I was going to do it. Of course, it was the Holy Grail for a Supervisor of Salvage to do something like that.

I prepared two plans. It turned out we would have had to make a significant draw on both the Atlantic and Pacific salvage resources, ships and people, and, of course, it would have cost us less money. On the other hand, we could have done it with commercial resources. We had an estimate that said it was going to cost \$8.6 million. That was sight unseen. Nobody had been to the canal and done it in six months.

I told everybody that we could do it for \$10 million in six months. Again, that is even before my meeting with Bill Clements. We had those numbers and that was why he thought it was

outrageous and impossible. We were going to do this for eight or ten million dollars, using two cranes that cost only \$8,000 a day each. It was incredible. But in fact, it was fairly easy to estimate. You knew what resources you were going to start with and the daily cost of the resources. It was just figuring out how long it was going to take and you had a number.

Incidentally, as it turned out, we spent \$12.3 million, I think, which included a lot of Egyptian pounds. We bought a lot of our resources, food and stuff like that in the Suez, using Egyptian pounds. The U.S. owned them. They were not convertible. They weren't good for anything in the U.S. but were good for local use. All told, it cost \$12 million and took us six and a half months. No, it took seven and a half months.

At any rate, after the next meeting of the 'Elephants', I was told, "No, we're going to have the contractors do it." Remember, though, it was May of 1974. We were just getting out of Vietnam. Adamson said that the boss, meaning the CNO, did not want to get a bunch of Navy personnel in the Suez Canal, between the Egyptians and the Israelis, and get all shot up. He said that we were just getting out of Vietnam, so we were going to do it with the contractors.

That was how it came about. Then, we tasked the contractor, Murphy Pacific, to prepare the detailed plans, which I reviewed all the time, of course, and to go with their subcontractors. I was ready to go. It was in May. It was about the middle of May. There was one flight a week from New York that went all the way to Cairo and I had my tickets.

Admiral Kidd was also, as usual, very interested in all of this. There were certain financial restrictions, although the operation was going to be paid by the State Department, the Agency for International Development, and we had a strict prohibition against doing anything or spending a penny until we had the money in hand from the State Department. The Friday morning that I was supposed to get on the airplane to go up to New York and then fly to Cairo, we still didn't have the

money from the State Department. I told Admiral Gooding, “Hey, I can't go.” In the meantime, Admiral Kidd had been telling all his four-star buddies, “My salvage officer is going over there and we're going to clear the Suez Canal.” Oh, incidentally, I overlooked one thing. The operation to clear the mines and the land operation was all done under the joint command, under COMSIXFLT and CINCUSNAVEUR; and the Office of Secretary of Defense (OSD) route.

Since Mr. Clements was so convinced there was going to be a financial and technical disaster, he didn't want us to be a part of the joint command. He said, “You guys do it at NAVSEA.” In other words, we would divorce ourselves from the financial and technical disaster that was going to happen. I was going to be separate from the operation that was already going on over there. They had an admiral over there who was in charge of all the other parts of it and it already started probably a week before what I'm talking about. I was ready to go over on that Friday morning. Admiral Kidd was off somewhere and called his aide and of course, they talked several times a day. Admiral Kidd is a great guy. I love him, but he was a controversial person. He was also sort of mercurial.

His aide was Captain Pete Dejarnette. Pete called me up and said, “I just talked to Admiral Kidd. He's getting on an airplane and wanted to make sure you're en route today to head over to Suez.” I told him, “We haven't gotten the money yet, so I can't go.” He said, “Oh, that doesn't sound very good. I'll call you back.” He got Admiral Kidd before the admiral got on his airplane. Pete called back a few minutes later and said, “Huntly, put on your asbestos earmuffs. I quote Admiral Kidd: ‘If you don't have your ass on that plane this afternoon, you can meet me at Andrews Air Force Base when I return this afternoon with your resignation and tell me how dumb you are why I shouldn't reactivate Bill Searle, a former SUPSALV, to go over there and take this

job.” I went up to see Admiral Gooding. He said, “Well, we might go to jail together, but can you go?” I said sure. I still had my tickets. He said, “Well, go!” so off I went.

We had the two heavy lift ships manned with all former Navy people, most of whom had served on them in Vietnam with Harbor Clearance Unit One. The contractor brought in first one and ultimately, two heavy lift cranes from Germany. We had a very small Navy cadre. I had three or four officers with me. When the operation got going, we had operations in the northern and southern ends of the canal, as well as the center, and I had an officer in each of those places. We had a supply officer and a SUPSALV civil servant, who did logistics stuff. We had one enlisted man, as I recall. He was a SEAL. A key man was Jim Bladh, retired lieutenant commander and diver. He worked for SUPSALV. He was our advance man and Cairo liason.

These officers rotated, so in all, probably six or seven diving and salvage officers were involved in the Suez Canal beside myself. We also brought a lot of people over for visits for a week each and paid for them with the Egyptian pounds. We bought their tickets in Cairo using Egyptian pounds, so we didn't use any U.S. dollars. The U.S. owned the money. It was useless to the U.S., except in Egypt.

The operation went pretty much according to Hoyle. There weren't many surprises. There are always little surprises when doing salvage work, but it went pretty well. Again, as I said, we originally estimated that it would take six months. It took seven and a half months from the time anybody got there.

Of course, when I got over there, there weren't any resources. There were a couple of weeks before the resources really got there; the people and the equipment. With this small group, we did this job. There were never more than about 120 contractor civilians on the job at any one

time, so the cost went along just as we had expected it would. That pretty much completes my SUPSALV time and my diving and salvage experience in the Navy.

INTERVIEWER: What about after SUPSALV? What was your involvement in diving after you retired from the Navy?

CAPT. BOYD: Oh, let me say one other thing. After SUPSALV, I went to the Norfolk Naval Shipyard as a planning officer and to the Puget Sound Naval Shipyard as a shipyard commander. One thing that I thought was important for my career was to keep my credibility and experience up to date in the more mainstream area that could support a full career after I finished diving and salvage.

I'm sorry to say that too many people get involved in diving and salvage and are so enthralled with it that they don't want to do anything else. Then, they come to get to be a commander and they ask, "Well, what can I do?" There's one ED captain job, and there are only a couple in the unrestricted line or the 1140 community, I think it's called - at least it used to be called that. They don't have much of a career path. In fact, the 1140 community, the diving and salvage officers, have been gobbled by the Explosive Ordnance Disposal (EOD) community.

I don't know that there's a single captain billet designated for a diver. There are billets that can be filled by a number of different specialties, but I don't know that there's a single diving and salvage guy who is a captain in the unrestricted line, in that kind of business, unless he has gone on to something else. The point is that in my case, and I tried to keep this going all the time, I had to make sure that I had my feet in two different career paths and when one dried up, I wasn't dead.

INTERVIEWER: Huntly, when you were at Puget or even Norfolk, you were, to some extent, still the senior ED salvor on active duty. During that time, were you consulted on various occasions by

the incumbent SUPSALV or used as a sounding board, or was it more like 'the king is dead. Long live the king?'

CAPT. BOYD: No. I think it was 'the king is dead, long live the king.' Oh, incidentally, I have a little bit of pride here. I was awarded the Distinguished Service Medal for the Suez Canal operation. Also, when I got over there, because of the difference between my chain of command and all the rest of the people, who were in the joint chain of command, I sent off my own SITREPS. I sent my SITREPS on Sundays, Tuesdays, and Thursdays, so they would be received in the U.S. Monday morning, Wednesday morning, and Friday morning, and things didn't happen that fast so as to require daily SITREPS. If anything really happened, of course, I could send off a message if I had to.

The overall commander of the operation was Task Force CTF-65. They made me the Task Group Commander. I was 65.7 and I'm probably the only ED who was ever Task Group Commander as an ED. When the operation was over, thanks again to my different chain of command, all the task group commanders were recommended for Legions of Merit and were all knocked down to commendation medals. COMSIXFLT, I'm told, had some heartburn about the operation over there. Somebody told me not to worry. Admiral Kidd was going to take care of me. In fact, he did. I was awarded the Distinguished Service Medal. I think I'm the only ED captain who ever got it while still on active duty. I was able to wear the Distinguished Service Medal for the last six years of my Naval career.

INTERVIEWER: You've gotten some other awards. I remember that you received the American Society of Naval Engineers Award for salvage engineering.

CAPT. BOYD: In 1966, I had come back from Service Group 3, CTF-73, as a Seventh Fleet salvage officer. I was selected by the American Society of Naval Engineers as the gold medal

winner for the year 1966. I was still a lieutenant commander at the time still. The selecting committee told me that they had quite a fight. All the previous gold medal winners had been scientists and very senior people. I don't know who the other candidates were, but they selected me. I was the first person who was selected for the gold medal whose background was an operational type. As a result, they changed the rules and they established a second top award in the society. One of them is unrestricted, like the gold medal, and the other one was really for technical lifetime achievement.

INTERVIEWER: Well, you've certainly had a distinguished career in salvage and also in the balance of the Navy. You served as an Engineering Duty Officer. By my recollection, you probably hold the record since World War II for the most salvage jobs done by any salvage officer, maybe (even more than) Chuck Bartholomew, but I'm only sitting in around at fifteen.

CAPT. BOYD: You're probably right. Including Suez, there are ten wrecks there. I've had forty salvage jobs that I was on scene and in charge. Technically, I wasn't in charge in the Suez. The contractor was in charge, but you can be sure that I was in charge.

INTERVIEWER: I was there. I know you were in charge.

CAPT. BOYD: As I said, the really lucky part of it was that only one of them was not completed successfully. That was the *Bache*, which wiped its bottom out before we could refloat her.

INTERVIEWER: Everybody has a rabbi. You mentioned Ike Kidd, who has been good for our community. Who, singularly, did you admire the most?

CAPT. BOYD: Well, the person who I admired the most and who had the most influence on me was Bill Searle. Bill was eight years senior to me. I remember that when I showed up at the diving school after MIT, Bill was completing a tour there as the assistant program officer at the EDU. He was a lieutenant commander. He was a commander selectee, as I recall. He sat us down and told us

sea stories and how great everything was. I said okay. I didn't pay much attention to that, but when I went to Long Beach, I was a docking officer. There comes the USS *Providence*, a light cruiser, and Bill was the chief engineer. I got to know him a little bit more. After the *Providence*, Bill went to be the Pacific Fleet Salvage Officer, so when I ended up at Service Group 3/CTF-73, he was my salvage rabbi in the west Pacific. Bill then went to SUPSALV and was the one, I'm sure, who convinced COMSURFLANT to put a salvor in the job as its assistant maintenance officer. That was how I got there, again relieving somebody significantly senior to me.

When Bill retired as SUPSALV, I relieved Gene Mitchell at the EDU. Gene went to SUPSALV, but Bill was still around. Bill was the kind of guy who was pulling strings and being interesting all the time. You remember how you would say that Bill would meddle a lot? I remember a story. There was a great diver named Vic Evans, an LDO diver. He was a lieutenant commander over in OPNAV. Vic stuttered or stammered a little bit and was called 'Vapor Lock' because of that.

Vapor Lock Evans once told me this story. Bill Searle, when he was SUPSALV, had to get something done or wanted to do something and had to get some help in the Pentagon. He got Vic Evans to set up a couple of meetings with him. The way he was, Bill would just blow into an office and take over. Evans told me later that one of those admirals asked, after Bill's visit, "Who was that man? That's the most interesting presentation I've had in a month." Another admiral told him, "Don't ever let that man in my office again. I never want to see him again."

INTERVIEWER: That sounds like Bill.

CAPT. BOYD: That's Bill Searle.

INTERVIEWER: You mentioned earlier the 1140 and the ED communities and the lack of jobs at the top, if you will, and the fact that the salvage unrestricted line officers are being gobbled up by

the explosive ordnance disposal community, who basically do have the bigger jobs or the bigger positions. Being aware of the current fleet level of ships in salvage and the activity in salvage, do you see the law of diminishing returns here, in salvage, for the Navy, as far as capability short of the contractor assets that the supervisor has available?

CAPT. BOYD: Yes, of course. When I was in the Seventh Fleet and the Atlantic Fleet, we had eight ARSs in the Pacific and five in the Atlantic, thirteen salvage ships full of divers, with about twenty divers apiece.

We had a whole bunch of ATFs. Although they weren't my responsibility, we had six or eight submarine rescue ships, all of which had big stores of divers. They're all gone. The ATFs are all gone. There are only three ARSs, and who knows how long they're going to stay around? They get a lot of publicity finding lost airplanes and things like that, but that doesn't pay the bills. Without the submarine rescue ships, there's no need for deep diving. Saturation diving training has just about disappeared. The billets are not there for either enlisted or officers. You're going to get to the point that it is diminishing returns if you are not already there.

It's like the British. They really don't have an RN-uniformed salvage capability. Their divers are what they call 'clearance divers,' which are EOD divers. They have no salvage capability to speak of, other than just basic know-how. They're useful in salvage, but I don't think they're trained in salvage. They have a civilian-operated division in the Ministry of Defense that does their salvage, mostly using contractors. I'd hate to see that happen, but that may be what's going to happen to the U.S Navy.

INTERVIEWER: You and I both recently attended the National Salvage Conference here in Washington, D.C., and you could have taken from that that there will be new regulations coming that could be a shot in the arm for the salvage industry, in terms of more exercise play, and retainer.

Second, the bulk of the salvors today, other than Titan, probably have day jobs in towing and marine construction, et cetera. I'm leaping forward into the post-9/11 world, in which we theoretically think that we have this firehouse capability with these waterfront construction companies. I'm just thinking of some marine terrorist disaster for which my gut feeling is that even on the civilian side, we may not have the resources in the form of hands-on salvors. Certainly, the potential Navy addition of search to that would be somewhat minimal.

I'm just thinking that with this new scenario, recognizing that it's not a defensive issue, just a causal relationship, we're going to have another terrorist activity. It could be a marine one. It could be significant. What would be the capability of the country to respond, recognizing the existing commercial salvage and probably the minimal capability of the Navy at this time? I'm wondering if in the new makeup in NORTHCOM or whatever we have, there is a role there for these skill sets to be employed.

CAPT. BOYD: Are you talking about a military capability?

INTERVIEWER: We're talking about either military or a combination thereof. I'm going back to a marine board contribution you made some years ago. When the threat of 6,000 TEU container ships going adrift and the lack of availability of major towing assets up and down the coast, I think we were looking at station ships or some capability like that, at that time. Incidentally, that is what's done in the U.K. If we had gone forward with that, then I think we would be better prepared. One can think of the fire ship that was sent into the battle in ancient times.

What if someone had the equivalent of a fire ship coming toward any of our major ports or something like that, and we had no snap-on and pull-away capability with tugs of any appreciable horsepower? I'm just posing this to you because I don't want to say you're the last of the salvors, but

you're probably the last of a breed. I don't think the opportunities are going to be there for our people to get experience, but I don't have a good idea on what the fix is.

CAPT. BOYD: Well, it's a very difficult question. Unless the country wants to invest the money, and I don't think it will, the Navy capability will peter away. But if the government wants to invest in standby Navy salvage capabilities, that could be done. After all, the standby aspect of the whole military is just that in normal times.

I don't think it's necessarily the all-plus because the people assigned and involved in that as if they were standing in the firehouse when there's no work to be done, they'll tend to atrophy. Their experience levels will deteriorate, their interests will deteriorate, and they'll get fat. That happened in Europe. Some countries paid for standby salvage capabilities and didn't use them. That happened to the U.S. Navy. In my time, we had three commercially operated former Navy salvage ships under contract and they were allowed to do commercial work. But Navy work, if it came, took priority over commercial work. During my time, those ships weren't impressive in their capabilities. They managed to keep a few old timers on board who were really good men, but the capability that had been there to start with atrophied because of less and less work, and it cost more and more money. There is a downside to paying for standby capability.

Also, a standby Navy capability is going to compete against commercial activity and capabilities, so it's a very thorny thing. We see right now that there's an issue up in the Puget Sound, and I don't know who paid for it. I think the Coast Guard paid for a lot of it. There was a standby tug in Port Angelis, I think, or someplace in the entrance to the Puget Sound. It came time to renew the contract and there was a big question about who was going to pay for it and how much money it was going to take. I think it's been resolved favorably, but you can see if there's no action

to remind people why they're there, it's going to disappear. The sources of the funding will just let it slide away.

INTERVIEWER: Looking ahead a little, you've been around a while. You've been able to observe things both commercially and in the Navy. We're making moves in the technology area, I think, on the heavy lift salvage side. It is 'use a bigger hammer or more hydraulics,' et cetera. But there seems to be a lot of focus on underwater vehicles and the standard diver threat to the vehicle, et cetera, but the vehicles can clearly go deeper than divers can. Are you encouraged with this kind of ocean activity? Forget about our mutual salvage interest, but consider the way we're going forward in the ocean now, compared to where we've been?

CAPT. BOYD: Well, as you know, the commercial diving industry has surpassed the U.S. Navy in its deep diving capabilities. Why? Because they had the need to do it. They have better training facilities. They no longer have to rely on former Navy divers, as they used to, and they're way ahead.

Even so, even in the commercial area, where they have tremendous deep diving, 1,000-foot capability, 1500-foot capabilities, the move is toward doing the job without a diver. If you have to have a diver, a man on-site, the move is toward doing it in a one-atmosphere capability, a one-atmosphere suit or one-atmosphere observation submersible. That's the way it's going commercially, as well. You saw the salvage of the *Kursk*. It was a marvelous job. They used very few divers. The only thing they used divers for, I think, was cutting the holes to put in these big 'flowerpots' to lift the ship. The sawing of the ship in half was done without divers. Except for actually cutting the holes and attaching a messenger, I think all of the connections for lifting it were done remotely.

We have the Navy lifting of the *Ehime Maru* in 9,000 feet of water. That was all done remotely. If there's a need to do something deep, it can be done. It's going to cost a lot of money, but it can be done. You don't have to have divers. As to the second part of your question, the facilities are getting better and better. When we did the Suez, those 500-ton sheer leg cranes were state of the art. Now, there are whirly cranes that are 5000 or 6,000 tons, and maybe bigger than that. Of course, they're terribly expensive. They are big enough to lift the whole oil production platform off of a barge and stick it on the jackets.

INTERVIEWER: While we're talking about technology, what do you think has been, based maybe on our narrow field, the most significant advance in technology in diving or salvage in the last fifty years?

CAPT. BOYD: Well, it was saturation diving, of course, and improved decompression tables. Mixed gas diving has come in the last sixty years or so. SCUBA and closed-circuit SCUBA were very important. In the traditional salvage area, the hydraulic cable puller is a tremendous advance. Instead of having complicated falls of four-part sheaves to pull on a wire, cable pullers are much safer, much faster, and much more convenient.

We already mentioned heavy lift cranes, which were a really significant advance, although not so much in the U.S., high-horsepower tugs. When I was doing it, our 3,000-horsepower ARSs were the best there were. Now, you've got harbor tugs that are more powerful than that and driven, perhaps, because of the mammoth growth in size of ships, but mostly overseas tankers. You have tugs that are 15,000, 20,000, and I think 25,000 horsepower. They're certainly significant to the salvage capability where they happen to be. The biggest salvage organization in the world is Smit, and they've got several big tugs but will take any job that they can. When one of those tugs is towing an oilrig from Singapore to Alaska, it's not available for salvage.

Again, as you say, even the biggest has to have a day job to keep paying the bills. But the bigger companies have a better opportunity to employ salvors and keep them employed, so you can get them to the job when you need it. The philosophy now is to use a fly-away. Don't worry where the tug is. You can get people to a site pretty quickly and make do with tugs of convenience.

Another tremendous advance over the past thirty years is the underwater positioning and locating and precision navigation capabilities. We couldn't do many of the marvelous things that they now do without those capabilities. They've all come in just in the last 30 to 35 years.

INTERVIEWER: This interview is supposed to reflect the last hundred years of Navy diving. You've managed to plug into the middle of that, if you will, and maybe more so in the back half of the last fifty years, but in your early days, there were probably some, as you mentioned, World War II experienced salvors who did a few neat tricks and survived. But looking back over a hundred years and the history of Navy diving, if you will, do you have any general statement or comment, going back to this past, present, and future idea? In other words, theoretically, we learn from our past, but sometimes, we get a lot of this history repeating itself, as I think you mentioned. Bill Searle and I think that during the beginning of Vietnam, we found ourselves on somewhat of a short leash for resources and things with which to go to work. You've probably seen that cycle more than once or twice in your career, but surely in the last hundred years?

CAPT. BOYD: Well, the divers in 1920 always amazed me. The submarine that sank off the entrance to Honolulu, Pearl Harbor, is in 304 feet of water. I think it was the F-4. Divers dove on that ship using air and managed messengers and wires underneath the ship so that it could be actually lifted and dragged out. It was 304 feet under, and they were diving on air and doing hard work.

It was just amazing how those men could have done that. Even the USS *Squalus* was 248 feet down. They had a hard time, but they did it. Of course, they were just bringing in helium-oxygen mixed gas diving in those days, and I think this was the probably the first operational use of mixed-gas diving.

In fact, as I recall, I think they took divers from the EDU up to do the job. They did all the diving. The salvage ship, the USS *Falcon*, had divers who probably weren't trained and didn't have the equipment to do the helium-oxygen diving. It just seems that those Paul Bunyans of the past aren't around any more. Will we need them in the future? Sure. We need not only physically fit but smart people. Will we come to a time when we find that we suddenly need to significantly expand the traditional Navy diving community? I don't know. I just don't know. It's hard to maintain for a whole career, especially experienced officers. That's what you need, career divers and career salvors. It's hard to maintain them as an appendage to the Navy when they have limited funds and requirements for other things.

Like the fire department, they don't get the attention they need to keep them going until they want them. Then, they find out they're not there. Incidentally, speaking of the fire department, you ask, "Well, what's wrong with the fire departments in the U.S.? What's the analogy there?" Well, the analogy works because firemen get exercised all the time. They're in use all the time. If you go to the fire department in a small town made of brick houses, where they don't have fires, they have volunteer fire departments. Even if they had a full-time, professional, fire department, they would atrophy just like a standby salvage ship would if it didn't have things to do.

If we came to a need tomorrow and had to vastly expand our diving capability, I wouldn't be surprised that the route would be to recruit trained, experienced divers from the commercial sector. Even in our day, if you needed to do underwater welding, the Navy diver was trained to do it. He

didn't do it very well because he didn't do it very often. If you wanted a professional welding job done underwater, you get a professional. The way the commercial people do it is they take a welder who's a good welder and they train him to dive, not the other way around.

INTERVIEWER: That leads to this, and I think you alluded to it earlier. You were a salvage officer, salvage engineer, salvage master, and a diver, and a lot of people think that diving is your job. As you understand it, as I glean from your remarks, you really have to have a reason to dive. It's a tool to use to do what you want to do, be it explosive ordnance disposal or maybe more of a uniquely commercial diver, but he'd better be a skilled artificer. I think that some people lose sight of that, that it's just a tool in your sea bag. You mentioned in your earlier remarks how it was a valuable capability to you. You've been there, done it, gotten the t-shirt, and were able to, on occasion, get in, get down there, and get a first-hand look at the situation before you drew any conclusions or started any analyses. My sense is that in the Navy diving world, some of these guys are still thinking they're divers when they really should think that they're salvors, EODs or SEALs. I think you mentioned picking up airplanes, which now seems to be the only work we've got because ships don't seem to be going aground. But if you do not have the other skill sets, being a diver, in and of itself, isn't all that much unless you're going down to Cancun or something.

CAPT. BOYD: That's right. We don't train divers to put on their flippers and SCUBA gear and swim along a pretty reef. That may be rewarding, personally, but we're not going to pay people to do that.

INTERVIEWER: Well, Captain Boyd, this more or less concludes the interview. I appreciate your time. I think that was a great summary of the Suez Canal. In fact, I, having been a student of the Suez Canal, picked up a few more points that I didn't know.

CAPT. BOYD: I have one more little story in which you would be interested. When we salvaged the *Card* in Saigon in 1964, we became very concerned about the Saigon River. It's fairly narrow in many places and a torturous trip to Saigon. It has a large tide. It is surprising how large the tide is all the way up into the city of Saigon. We were concerned that the river could be blocked easily. We used the *Card* incident as justification to form the first post-World War II harbor clearance unit. But we also needed heavy lift ships. The last of the U.S. Navy ARSDs had just recently been decommissioned, and they had been sold. They just weren't going to be coming back. Bill Searle, who was the Supervisor of Salvage at the time, was interested in the British lift craft. The British had some heavy lift ships, some of which were in Singapore. He was wondering about leasing the heavy lift ships from the Brits. In the meantime, the Philippine navy flagship, the *Raja Solomon*, a former U.S. Navy DE, was sunk alongside the pier in a shipyard in Marvellis. That's in Luzon, forty or fifty miles south of Subic Bay. The ship was down for boiler repairs and moored alongside the pier. A typhoon was coming. It was expected to peter out as it crossed the island. It didn't. If they had known, they would have taken the ship out and put it to a buoy. But it was alongside the pier and the power failed, of course, and the ship beat against the pier. As they always do, it capsized toward the pier. What happened was the ship beat away the fendering and pretty soon, there was nothing but big bolts and brackets and stuff like that. They punched a lot of little holes and maybe some big holes, too, in the side of the ship, so it capsized toward the pier.

We heard about it and Gene Mitchell, then the PACFLEET salvage officer, Bill Searle and I went to Singapore. En route, we stopped to see the *Raja Solomon* and the Philippine navy was making a desultory effort to salvage the ship. You could see they weren't going to get anywhere. We saw there was an opportunity to demonstrate the use of lift ships and to establish a precedent of leasing these ships from the Brits. We told the Filipinos that in terms of the lease of the ship, once

in excess of your need, it returned to the U.S. Navy. That was, of course, to keep them from selling it to a third country or something like that. Basically, we told them, “If you can't salvage the ship, you have to say to the U.S. Navy, ‘the *Raja Solomon* is excess of our needs. Come and get your ship.’” They did that. We built the story that we needed the lift ships to salvage the *Raja Solomon* and the easiest way to do that was to lease them from the RN in Singapore. We got them and used them to raise the *Raja Solomon*, first to parbuckle it and get it upright, then to get it to more shallow water, where we could pump it up and re-float it.

In fact, we never needed the ships. Lift ships are most useful when there is a significant tide. There is only a two-or three-foot tide in Marvellis. You'd use up the tide just stretching the wires to do the lifting. Nonetheless, we proved that we needed and could use the heavy lift ships. That led to leasing more heavy lift ships for use in Vietnam and ultimately buying the two German heavy lift ships, which were twice the capacity of the biggest British ones. Actually, they were three times the capacity of the ones we used in Marvellis. But the U.S. Navy did lease, I think, four of the British heavy lift ships for Vietnam, operated by Harbor Clearance Unit One, and ultimately the two big German ones, which were renamed after two former Navy divers, *Cirilley* and *Crandal*.

(Whereupon, the PROCEEDINGS were adjourned.)

# UNDERSEA & HYPERBARIC MEDICAL SOCIETY

## INTERVIEW OF ADMIRAL IRISH FLYNN

Wednesday, March 17, 2004

## PROCEEDINGS

INTERVIEWER: It's March 17, 2004, and this is an interview of Irish Flynn by Dick Vann.

ADM. FLYNN: Happy St. Patrick's Day.

INTERVIEWER: Well, Happy St. Patrick's Day to you, you old Irishman.

ADM. FLYNN: Well, let me give you just a synopsis of my time in the teams. I joined the United States Navy in 1960 and went through UDT training. I went through replacement training at Little Creek that same year, and I reported to UDT 11 in Coronado in October of 1960 as an ensign, USNR, and served in UDT 11 until 1963. I was in SEAL Team 1 from '63 to '65, staff duty in Washington from '65 to '67, and SEAL Team 1 and UDT 12 from '67 to '69. I then had various school and staff duties until I returned to Coronado as chief of staff of Group 1, in 1977. That lasted until 1979. Then, I had more duty in Washington, followed by command of Group 1 from '81 to '83. It was in those times that I was in the Naval Sea Systems Command in Code OOC from 1970 to 1972. At that time, I was involved in the acquisition of SDVs and the diving systems. When I got to the teams, I hadn't had diving training on the east coast. In those times, you went through UDT, reported to the team, and then the team sent their new people to Key West for diving training.

INTERVIEWER: Can you tell me when the underwater swim school was started?

ADM. FLYNN: Oh, it was long before then, long before 1960. I don't know what date that was because I never attended it.

INTERVIEWER: Oh, okay, fair enough. Sorry.

ADM. FLYNN: I came out to Coronado and was in the teams for some months before there was an underwater swimming course for team members. I did not do it with the trainees. On the west coast, SCUBA training was part of UDT training. When the people came to the teams, they had already had SCUBA training.

Well, not having had that, I was in a pretty small class with just a few people. It was run by the UDT section of the amphibious school, and Kevin Murphy was the principal instructor. Kevin, as you know, when he retired, went on to work for U.S. Divers. He's a very accomplished guy and knew his diving physics and diving medicine very well. Various corpsmen, and I could dare say the doctor, lectured in that course. What we learned to do was swim and dive with aqualungs. We did free ascents with a bell that was suspended from a Mark 6 LCM, which was used as a diving support by the UDT. It went out by the entrance of the bay out by Ballast Point. You free ascended from about 35 feet, rather than the 100 feet or so that east coasters probably did at New London.

INTERVIEWER: Do you recall who the medical officer was, the DMO, at the time?

ADM. FLYNN: The first one, I don't recall his name. There was a doctor there who nobody had very much confidence in because there had been an accident on the strand, and the guy was pulled out of the water. He died, and the doctor pronounced him dead, but the team members thought that not enough had been done to resuscitate this guy. I thought there was an awful lot of emotion in that, rather than science. Why would the doctor have said he was dead if there were any signs that he was still alive or capable of being resuscitated? Anyway, that was the knock on this doctor, and he wasn't there for very long before he left.

What was I trained in? We still had Pirellis in the team. That was not a circulation thing, but they were phased out. There were just a very few of them left.

INTERVIEWER: The Pirellis were a pendulum system?

ADM. FLYNN: They were a pendulum system. People used to call them the 'black death' because you could have a problem of just re-breathing, literally, the same air without it going through the canister and getting oxygen depletion combined with CO<sub>2</sub> build-up if people were working hard with them.

The Italians had used them principally for charioteers who were riding on, in effect, SDVs. The Americans used them while swimming horizontally with a very high work rate of underwater swimming. Maybe that was part of the problem with them. But all I recall is that there were a few of them still on the team. What I was trained in, in addition to the aqualung, was the original Draeger. I think that was the Mark 5 Draeger.

INTERVIEWER: Was there a Lund Draeger?

ADM. FLYNN: It was the Lund Draeger, and it was an excellent diving rig. I enjoyed swimming it because it was super for getting in and out of boats and things because it was lightweight. To my mind, there may have been a good reason for going away from it. The good reason was that they weren't able to get repair parts, particularly to repair the bags, which were inclined to leak because they didn't have clam shells over them, as the later Draeger has.

INTERVIEWER: Did the Lund have a circuit system or was it a pendulum?

ADM. FLYNN: It was circulatory.

INTERVIEWER: It was?

ADM. FLYNN: It was an excellent piece of gear. You were able to keep water out. Occasionally, if you weren't careful, you could get sea water around your mouth. Some of them had pin prick holes in the bags, too, because they were wearing out. You could get water in that way. When you did, you got a caustic wash into your mouth, but that only happened to me once or twice in a good bit of swimming, and I only got it into my mouth. I didn't get a good lung full of the stuff like some guys did.

INTERVIEWER: Can you compare the Lund with the new Draeger LAR-5?

ADM. FLYNN: Let's see. How does it go? The bottles, were they in the back? The oxygen bottles were, I think, in the back. In your front, you had your bag. Within that bag, fitted in through

the bottom, was the canister. Frankly, I'm not positive of that. The oxygen bottles may have been down below the canister. But it was very likely the Mark 5, with the exceptions of the clam-shell and the positioning of the oxygen bottles. The oxygen bottles on the Mark 5 were in front, and they were behind with the Lund and lightweight. It was made for combat swimming, but we did comparatively little swimming with it.

The swimming that we did with it was typically off the strand there in Coronado. You got a boat, loaded it through the surf, and were taken off 1500 yards or a mile and did swims in, with the target being the headlights of trucks on the beach. We also did that in the bay. Very occasionally, we would actually do attacks. We did do attacks with them out at sea off San Clemente. I remember doing that and doing a good deal of diving.

For example, when we did lock-outs from submarines, I don't recall ever using the oxygen rig. We used aqualungs and hooka rigs for that. We did hooka rig ascents and occasionally free ascents, buoy ascents. As I said, there were parts problems with them. Then, somebody got hurt with one somewhere. I think it was on the east coast. There was somebody killed on it, and people said that it was an unsatisfactory piece of gear, and NAVSEA designed something new to replace it, the Emerson.

INTERVIEWER: What year did the Emerson come along?

ADM. FLYNN: I'd say it was 1963 or so.

INTERVIEWER: Did you ever have one?

ADM. FLYNN: Yes. When I went to Vietnam in 1964, the CIA had bought many Emersons for the Vietnamese to use. They were pretty hopeless pieces of gear, but we trained the Vietnamese in the use of the full-scale Emerson. I must have gone through Emerson training perhaps as early as 1962, certainly by 1963.

INTERVIEWER: How did you find the Emerson in comparison with the Lund?

ADM. FLYNN: It was clunky and noisy. You had the clam shell in the back and bags in the front. From the swimmer's point of view, once you were in the water, it was okay. But it was an engineer's design, rather than a war fighter's design.

INTERVIEWER: That's a tactical disadvantage, isn't it?

ADM. FLYNN: Tactically, it was a bit of a mess. It looked like a mini Mark 6. Instead of being compact, like something that you could put into a kit bag, it was bigger and had the problems of noisiness and visibility. We came up to take a look with a Draeger. There was nothing particularly visible. Since it was very lightweight, you could go across a beach very handedly with it. You could turn off the oxygen supply, close the mouthpiece, and run around with it because it was so light.

The Emerson wasn't all that heavy, but it was a noisy bugger with that plastic thing. If you banged into anything, it didn't make a great deal of noise, but it made some noise that you didn't want to have. Also, even though it was painted black and things would scratch, it was a more reflective surface. Again, it was perfectly okay to swim it. At the same time, I was introduced to the Mark 5 mixed-gas rig and trained in that.

INTERVIEWER: Now, the Mark 5 was a predecessor to the Mark 6?

ADM. FLYNN: That's right. The Mark 6 is a better piece of equipment than the Mark 5.

INTERVIEWER: What were the differences?

ADM. FLYNN: Gosh, I don't recall. I think it was somewhat more complicated to set it up with the gas settings. As I recall the physics end, the calculation of your equivalent air depth, equivalent of the dive and repetitive dive tables, they were very, very similar. They may have had less flexibility in setting. I recall 60-40 as being a typical mix, and I think it may have been a little bit

bubblier than the Mark 6. You got a larger stream of bubbles from it. I think it was more cumbersome and heavy. But neither was a particularly good underwater combat swimmer thing. They just weren't particularly made for that. They could have been fairly decent in SDVs, but we didn't have an SDV worth anything at the time.

INTERVIEWER: I recall my experience swimming around pilings and harbors with the Emerson. It was so noisy.

ADM. FLYNN: Bong.

INTERVIEWER: Yes, whereas the Draeger was all in front of you, and you could protect it. It made a big difference.

ADM. FLYNN: Yes. That was the way that I found it, and it was a difference of approach. The difference of approach, if you want to know my understanding of it, was that we were never all that serious about going to war this way, because the United States didn't need it. The United States had a huge Navy with lots and lots of submarines armed with torpedoes and lots and lots of carriers with bomb-carrying planes. For example, if we screwed around with the Vietnamese, having them attack in North Vietnam, it was more a pin prick than a serious way of destroying the aircraft. But when the United States, after the Tonkin Gulf incident, really wanted to destroy them, they just bombed the heck out of them.

Now, the Italians, in the Second World War, needed to have something pretty slick to get at the British targets in the Mediterranean. They had the underwater swimmers and the establishment at La Spezia in order to do that. When I, along with Gene Mitchell and Chuck Lemoyne, visited La Spezia in 1972, they were still very seriously into that because they didn't have the reach with their conventional Navy to get to Russians and others. They were thinking of Russian surrogates. Where

the targets were, I'm not all together sure, but perhaps they were in the Adriatic and maybe even going into the Black Sea. I'm not sure.

On the other hand, when I joined the teams, part of the notion was to use SCUBA for taking the World War II beach reconnaissance and doing it underwater. Teams put forth immense efforts, particularly with the Mark 6, into doing that on the east coast, where we had nice, clean, clear water and a good environment to do it in at St. Thomas.

INTERVIEWER: Can you summarize that effort, program and what difficulties led to it not being successful?

ADM. FLYNN: The underwater reconnaissance of beaches?

INTERVIEWER: Yes.

ADM. FLYNN: It was essentially an attempt to do underwater what was done on the surface. From the surface, the attempt was to do a 50-yard grid from the three and a half fathom line into the water line of taking soundings in depth and in the shallow gradient that was a very large area. Even in a medium gradient, it was a large area with a fair amount of surf breaking over it, with the surf effect reaching down to the bottom sometimes.

People were. to establish this grid, were using great long flutter boards with lengths of line many hundreds of yards, and swimming with compasses to lay out a base line. Then, people were swimming a base line parallel to the beach. People were also swimming vertically from that with compasses into the water line.

It involved an awful lot of swimmers, fairly problematic about whether they were actually doing things on an accurate grid. Those parallel lines into the beach perpendicular to the base line I dare say a lot of them crossed. But what you did get was a fairly good impression of what that beach area was. Were there any rocks, shells or really prominent sand bars in it? You could get

that from this evolution, but you could probably get as much useful information by just two or three guys doing it.

INTERVIEWER: Did they ever do a comparison between a conventional hydrographic reconnaissance to see how the charts compared?

ADM. FLYNN: Probably, yes. When they really had it going well, after lots and lots of practice, you could get pretty good at it. But it involved either a really strange thing by which you were going through all this effort to do this underwater, but you've been delivered by an LCPR or an LCPL that's on the surface, so you have to say, "Huh?" We could approach this beach in a boat, and nobody was going to do anything about it, or it involved doing it from a submarine.

In most places, the gradient was such that for a submarine to have enough water under it to do the lock-on, there was only a very limited number of boats that could bottom. You were out there in fairly deep water when you were locking out, which meant a long haul to the beach.

Typically, people would lock-on through a standard escape trunk. It would be two, three or a maximum of four at a time, and they would breathe air from bottles that were tied along the deck of the submarine, until everybody was out. On a signal, they'd then take off. It was a complicated business because people had a lot of gear, their buoyancy could be off a bit, and we lost a really good sailor who was swimming with Bob Valentine off San Clemente. They came off the beach. We were going to swim from the submarine into northwest harbor someplace, where there's a beach, and do this evolution. They had all this gear with them. The guy was holding this gear and getting ready, having just come off the deck of the submarine, and he went into the screws of the submarine.

INTERVIEWER: Oh, gosh.

ADM. FLYNN: He was last seen going down into very considerable depth. Valentine followed him for some depth, but it was probably, oh, a couple of hundred fathoms there, so there was a limit to how far he could go. That man died. He probably was using an air SCUBA because the description of it was that the manifold was broken by the screw, and all these bubbles were coming out. Mercifully, one hopes that he was hit in the head by the screw and killed by it, but we don't know.

It had those disadvantages. What you had to do when you had a submarine that could not bottom, the submarine was doing an approach while you were doing this. Then, when it was at the closest point to the beach, and you knew the course would be from your drop-off point, they would flash a light in the escape trunk. That was your indication that you were at the drop point. This guy would give a signal and everybody would roll off the deck of the submarine and go to it.

Well, if they had the currents right, if the submarine could come in during the first instance and gauge what those currents were, well, maybe you could make it to the right flank of the beach. But you were starting to build up errors along the way, and the compasses were notoriously unreliable, as were the depth gauges.

The depth gauges that we had on the tack boards were not all that great, and you'd tap them to make sure that you weren't exceeding depth. But that usually wasn't the problem because people swam fairly close to the surface, and it could be done using the extended duration that the Mark 6 gave you.

But from the point of view of going to war against the Russians, would you really want to have a submarine screwing around in that shallow an environment, that close to the shore, with a fair amount of bubbling coming to the surface, a fair amount of underwater noise from all of this? Among other things, you used to rendezvous with the submarine. You lined up on the line and

snagged the periscope, so they had to have a periscope up, which was not a healthy thing to do that close in. You would also do everything from banging on pipes to signaling with an underwater sound generator, an acoustic signal, and none of that were healthy things to be doing in a defended area.

But, lo and behold, we did much of it in Vietnam, but on the coast. An awful lot of the coast of South Vietnam was surveyed and surveyed again and again by units that were supported by a submarine such as USS *Tunney* and also by detachments that were out on LPDs, the USS *Cook* and *Dyshenko*. The way of doing those beach surveys wasn't an awful lot different when it was done from the submarine, because it was done from the surface with IBSs out. The swimmer would swim into the beach with a line, with the swimmers coming off one or more IBSs as bunting came up on 25-yard intervals or 50-yard intervals. You'd start at one flank and just go down with the IBS. A guy would walk along in shallow water at the inboard end and take soundings as it went along, guesstimating the lateral distance along the beach as we were doing it.

We got a fairly accurate reconnaissance of beaches that already had been reconnoitered three times by then. That really didn't change an awful lot. During the monsoon season, you got some shifting of sand bars but not enough to make a difference as to whether an amphibious landing could take place on them.

INTERVIEWER: This was really an operational use of the underwater hydrographic reconnaissance?

ADM. FLYNN: No. What we did was on the surface. All those swimmers were on the surface.

INTERVIEWER: It was all done on the surface?

ADM. FLYNN: It was all done on the surface, whether by night from the submarine or in broad daylight from the APDs. There has got to be a better way of doing this underwater thing. One way

to do it is with a lot of the components of the swimmer support system, the need for a long-range, bubble-free, mixed gas rig leading to a very good piece of gear designed by Westinghouse. For complicated reasons, we went away from that to the General Electric mixed-gas rig, which was really big and cumbersome.

INTERVIEWER: Was that the forerunner of the Mark 15?

ADM. FLYNN: It was the Mark 15.

INTERVIEWER: It was the Mark 15?

ADM. FLYNN: Yes. It was the forerunner of the Mark 15; it became the mark 15.

INTERVIEWER: Well, what was the Westinghouse rig that you had liked?

ADM. FLYNN: Only about two or three prototypes were made, and when I was in NAVSEA, I bought the argument that we ought to have a common rig, that we were going to use this General Electric rig for both deep diving excursions for saturated divers and also for our purposes. I think that what really went on is that General Electric had undo influence with some of the guys who worked for Gene Mitchell.

INTERVIEWER: Interesting. What year was that?

ADM. FLYNN: That was 1970, because when I was in the Pentagon, in 1965 to 1967, we launched the operational requirements documents for the swimmer weapon system and the swimmer support system.

INTERVIEWER: My gosh. It really takes a long time for those things to mature, doesn't it?

ADM. FLYNN: Oh, God, yes. But what we were looking for was an SDV, a large people carrier and a smaller one, and one that we hoped would be stable and operate effectively in shallow water, and that became the Mark 9, the flat boat with twins.

We were also looking for a very low acoustic signature, a bubble free, mixed-gas rig. Then, we were looking for a way of doing that underwater reconnaissance by incorporating inertial systems into an underwater system and acoustic triangulation on it by putting out buoys as closely as possible to the known distance. We were trying to triangulate from that when swimming in what was called the 'swimmer navigation reconnaissance system,' I think.

We worked on that a good deal to try to get it to work. I think eventually, long after I was the Commodore in Coronado, and that was up until 1983, that came to pass. In the meantime, we got involved in mine hunting, using the Mark 6 and then the Mark 15. The Mark 15 was a little bit dangerous because what we really needed was the EOD version, the Mark 16, to screw around with mines. But the idea of landings on the coast of the Warsaw Pact did actually say, we're going to encounter mines on that, or if we have to go into North Korea, we're going to encounter mines, and those mines in many instances are going to be scoured. They're going to be covered by sand.

The way we were graded in mine countermeasures exercises was people would put in mines. They would fairly promptly scour under the sand. At any rate, they were going to be pretty darn difficult to find unless you actually swam right up to them. We were fortunate enough to do that, and these things were sprinkled along Coronado Beach, for example.

Then, you got graded on your ability. If there were twenty mines put in there, and you only found two, well then you were a bunch of bums. I argued, unsuccessfully, saying, "Hey, we found two mines." We had to say they probably just didn't fall off something. It was an indication that there was a mine field there. That was already a great accomplishment. What we had to do was go back by other means, concentrate overhead collection using water-penetrating optics or lasers in order to do it, blue, green lasers and the like. We had to do that in order to be able to take a really

good look at that bottom, take away the clutter and see whether there were any anomalies on that bottom indicative of the presence of mines.

Further, we should ask ourselves, “What's the beach lane doctrine of our opponents?” If you find two or three mines, as we did, what can you assume about where the others should be laid out? Can we then use that to go back and look for the others on a separate mission if we do have to send swimmers back?

INTERVIEWER: Would you clarify the mission with regard to shallow water mine hunting and the teams in those days, particularly as compared to EOD missions?

ADM. FLYNN: EOD would be used, I think, to render these things safe. As in the Second World War, the frogmen were looking for beach obstacles, some of them with small mines attached to them. That became our job. Now, what we were saying in the late 1970s and early 1980s was that the fact there were no obstacles along the beaches did not mean that they were not defended. They were probably defended by a lot of mines, cylindrical mines. Then there were plate mines, and there were various kinds of them developed by Warsaw Pact nations. These things would have very seriously complicated and led to the defeat of any amphibious landing craft.

The Navy was going at it through several approaches. One, they had to find out if the mines were there. That was the UDT job. They thought of a number of ways of having to deal with the mines. The problem was getting rid of the mines way ahead of time. Well, you might be in peace. That was not a good time to be letting off explosives off the coast of another nation. If, on the other hand, you wanted to get rid of them and leave such a short interval between the clearance and the actual landing that the enemy wouldn't be expecting the landing, and defeat it by other means or leave them with enough time to replace the mines, what you had to do was have some way of getting rid of the mines practically instantaneously before the landing or in the course of the

landing by using line charges and other things to clear lanes. It was a big problem then. I don't think that the Navy really solved that until the Cold War was over.

By 1982, the UDTs had been re-designated as SEAL teams but with the combined missions that formerly belonged separately to SEAL teams and UDTs. They were to go in, in a way that they would not be discovered, so again, it involved operations from a submarine. We did these practice things with swimmers. The real way to do it was with an SDV and to figure out in an operations analysis how many discrete cross sections of a beach would you need to take and not find mines, in order to determine that the entire beach was not mined. You couldn't go over every square yard of the thing underwater. We needed courageous operations analysis to be able to say, "If you do this, this and this and you don't find a mine, then the probability of that beach being mined is 0.01 percent."

INTERVIEWER: That was a statistical problem, wasn't it?

ADM. FLYNN: You had to know doctrine. It was a statistical problem, and you had to know the enemy's doctrine about how he was going to put mines in there. If there were only one or two mines in there, and say you're invading Russia or the coastline of one of the Warsaw Pact nations or North Korea. You expect to have some losses. If you mess around, trying to find every single mine in there, what will happen is you'll be discovered doing it. The enemy is going to know that that's where the landing is going to be. They had to trade off those things. Now that was the reconnaissance mission. The other mission was the attack mission. Initially, we started building capability without really figuring out what we were going to attack and why underwater attack by swimmers was going to be the preferred means of attacking.

For example, if you had to have a submarine deliver you most of the way to get into an SDV and go put a limpet mine on a ship, why was it not better for that same submarine just to lay

some mines at the entrance of that harbor so that you were going to go through all the excruciating difficulty of getting the limpet onto it? When that ship came out, it would be destroyed by the mines or at least give the Russians a sense of having to deal with the mines before their ships could come out of that port. There was a lack of adequate strategic thinking about it, and part of that was because we didn't have sufficiently senior people at the time. Our senior people were captains, and we were given fairly respectful hearings on those. We started to get SEALs like Bob Mabry and Bruce Dyer, for example, onto the 7th Fleet staff. Similar efforts were made on the east coast to get people on the 6th Fleet staff.

There were commanders and lieutenant commanders on the staffs of the fleets, with views of looking at things in an integrated way and determining in what circumstances it is best to risk putting people into the water to attack things. One of them was to go after a nest of mine sweepers in a port at the southern end of the Kamchatka Peninsula at the La Perouse Strait. The whole idea was to mine the La Perouse Strait to keep Soviet ships from coming out into the northwest Pacific. But you also wanted submarines or aircraft that would be laying the mines to get the mine sweepers.

There you were, in a pretty tough place up there at the southern end of Kamchatka or Sakhalin. Anyway, the water was cold. I don't know what acoustic conditions were like. You were going to be using an SDV, coming out from a dry deck shelter. That was a long evolution with the submarine going slowly at shallow water, a dangerous place for a submarine to be in a hot war.

Again, it depended very much on how accurate the navigation of the SDV was. We had put into them acoustic Doppler sonar navigators, with which you bounced signals, preferably off the bottom. By measuring the shift of the return, you would know where you were going at all times.

INTERVIEWER: What year was that?

ADM. FLYNN: We started developing and had the prototypes of those systems in as early as 1972. Working on attacking these things was into the early 1980s. I was working on it when I was with Group ONE, in 1981 to 1983. You know that the LAM was the Limpet Assembly Modular?

INTERVIEWER: Yes.

ADM. FLYNN: It was fifty or a hundred pounds each of those beer keg-like components. You could put several of them together with one firing train, and they were neutrally buoyant but still not all that easy to handle in and out of an SDV. There were a fair amount of explosives in a submarine, so there was a lot of effort to make these things sub safe but still have assurance that they would detonate. You didn't want to go through all of that, a very tough evolution of taking the SDV into a Russian port during a hot war. In order to be able to rendezvous with the submarine, to be able to deal with the succession of depths, you needed to be able to ultimately end up on oxygen for the last several hundred meters of the evolution and you were operating under the target. That led to the requirements for tables and being able to do the diving with a combination of several breathing media, mixed gas with the Mark 15, perhaps some of it done on air and then some of it on oxygen. You also had to be able to switch breathing media underwater. That was the kind of work that you were doing, Dick.

INTERVIEWER: Yes. That suggests to me how important it is to get the operational community together with the research community so that the researchers will have a perception of the operational limitations and requirements. I think that's missed so often in research that there's a tendency for researchers to go off in a direction that has a devil in the details.

ADM. FLYNN: They can come up with something that's physiologically sound and engineering-wise works but isn't the way that you have to use it in the mission.

INTERVIEWER: I'm sure that still goes on.

ADM. FLYNN: Well, I hope that they're breaking through on that. For one thing, the operators have to be explicit about what they want to do. Can you attack with aircraft-dropped delivered torpedoes? Can you attack the Italian fleet? Well, the British did that at Toronto, but one of the things they found was that Toronto had shallow water, and the bloody torpedoes would just stick into the bottom on the initial drop, so they had to modify the torpedoes and their procedures. All of these things are very sensitive to what it is you want to do. There are two things with the SEALs and the special warfare community. Now, they have admirals and all of that, but they still need to be talking to the theater commanders and chiefs to the war-fighting four stars and their staff saying, "We think we can do this. Is it of value to you? It looks like it's of value to us, and here are the circumstances in which we can do it."

Well, then you need to go get very fine grained about your operations analysis, of what do you need to do in order to accomplish this mission. Then, you say, "Oops, we've got to go to 500 feet on this." It's most unlikely, but let's say that. You need to go talk to the Dick Vann's of the world and say, "Okay, we've got an excursion to 500 feet in this. How do we do that? Okay, we need new tables, and by the way, the gear you have won't do it." But they're very much needed. The British are very good at that, getting what they call the 'boffins,' or the researchers, the scientist engineers and the physiologists, into the operational planning.

INTERVIEWER: Right. That makes very good sense, and from recent projects, I still think that on this side of the pond, it's not always done.

ADM. FLYNN: What can happen if you don't know what it is that you ultimately want to do? You can build a whole lot of capabilities that remain unused in search of a mission. You build a capability and then you feel there's got to be a mission for it. Well, not necessarily. It can be a huge waste of time and a waste of lives, by the way. For example, as you know, in the SDV work,

the men doing that were unintentionally put into very severe physiological stress. Some of them have died from it, from hypothermia, in missions. A young man at Keyport went into irreversible hypothermia. You know all the problems of dropping blood pressure from fluid loss and everything in those operations. I don't know if we are ultimately going to solve those things or if we're going to rely on tough guys.

Some of these guys, like Fletcher and some of the really good SDV guys, I talked to them later and said, "How did you prepare for these things? Would you build up your carbs beforehand?" The guy said I'd be so busy getting that damn boat ready that I'd have a can of Coke and a Twinkie before I got in it to do the mission.

INTERVIEWER: I know the scenario.

ADM. FLYNN: Or I would have a good cup of coffee. But they were brave, adept, absolutely unbothered by all of the darkness and cold and everything underwater and were enormously assisted by the kind of work that you were doing.

Ultimately, the Cold War ended, and I don't know what kind of missions people are thinking of for ASDS, the miniature submarine that is going to attach to a parent submarine. But it seems to me enormously important, again, that the research community knows what's involved in that. How deep do they intend to lock out from that ASDS? If it's very shallow water work, then you might have problems with embolism, because you're in an environment in which the pressure changes rapidly as you ascend between fifty feet and the surface. You've got to watch what you're doing from that point of view, but you don't have problems with the build-up of gases. But you need to understand that because damned if I know what they're going to do with that thing.

INTERVIEWER: Yes, sure. Well, let's touch on one point here as much as you can. That is the actual operational use of combat swimmers in either an attack or in reconnaissance, with breathing

apparatuses. In my understanding, that has not happened very often within the U.S. Navy. I think the one that I'm familiar with was the hit on Noriega's patrol boats. I think the one down in Cuba was actually done by Cuban swimmers, but we assisted. There was also the one that you mentioned about going into North Vietnam with the LDMN's.

ADM. FLYNN: Yes. In North Vietnam, we were training people, and they were really quite good. We were training them around Da Nang and in the Da Nang River. They could swim fairly prodigious distances.

INTERVIEWER: Were they using Mark 6's or Emersons?

ADM. FLYNN: They were using full-scale Emersons, and they were pretty good at it. But when they actually went to attack, they got caught and inevitably would be looking back on it. What it involved was going from Da Nang, in a swift boat, 150 miles or more to some place, like Dong Ha. That was not the smoothest ride in the world.

Then, you got into a rubber boat from that and went in the rivers of Vietnam, which are typically silted and have bars where they meet the sea. You needed to get around that and then launch the swimmers, and to do that, we tried to show them in maps and otherwise what they were facing. God knows we didn't realize what the currents were. This particular pier was tucked around a corner, and it was a fairly considerable swim to get in there with these limpets, attach them, and get away. We put them to the test by taking them up one of the local rivers and doing a full mission profile, a full simulation of it, and they did pretty well. But they were actually pretty gutsy guys who, when they found that they couldn't make progress in the water or whatever, just went ashore and walked along the shoreline to get to it. We didn't know that until after they actually went on the live mission.

INTERVIEWER: This was in the simulation that they went onshore?

ADM. FLYNN: The guys wanted to do it. They were good fellows, and by the way, that's something to watch out with the frogmen, too. Did you succeed in doing the mission? Yes. Now, tell me exactly how you did it. They may have done something that they could get away with at Little Creek or off the Silver Strand but aren't going to get away with off North Vietnam. That, in effect, was what happened. Those guys got captured, and the North Vietnamese held show trials with them. They were put into North Vietnamese jails, and I don't know what ultimately happened to them, whether they are still in jail or whether they've been released.

INTERVIEWER: About how many swimmers were involved?

ADM. FLYNN: There were four. The limpets were CIA limpets. Probably, the fusing on them was okay, but they were pretty small charges, with perhaps a kilo of explosives in them, but it was enough to blow a substantial hole in a patrol craft. Again, the United States was trying to create the appearance of a North Vietnamese resistance force, a North Vietnamese Maquis. It indicated to them that we were in the position to increase the support and recruitment of that. They were going to have just as large a problem with the resistance in the north as we were having with the Viet Cong in the south.

INTERVIEWER: I see.

ADM. FLYNN: It was utter malarkey. There wasn't a prayer of bringing that on because they never actually recruited anybody in the north. It was all the attacks from the south that were staged in ways to make it look like we were sabotaged by people in the north, which complicated all the mission planning because it wasn't straight forward 'let's-sock-them.'

Finally, we got away from that and just shelled them from the sea, which led to the Tonkin Gulf activity and other those things that were not good. But you're right. The only time when we actually launched was against Noriega's patrol boat down in Panama, and the guys who did it were

fine. They were doing their mission, and they did it well. Whether that mission needed to be done is highly dubious. Whether we ought to have been doing it in a way that was going to kill Panamanians was even more so. Why? We had been training with those guys days before. The United States Navy had a considerable presence. We had an Admiral down there who was training their navy, and it was not stopped. Aspects of it are Pearl Harbor-like, with us on the bad side.

INTERVIEWER: That's interesting. I've talked to a couple of the swimmers who were there, and it sounded like a really well executed mission just on the operational level. There was a lot of interest from the point of view of the swimmers, and that's what you would expect.

ADM. FLYNN: Norm Curley, I think, was the Commanding Officer of the team. He was one of the best operational guys. He fought operationally and lived operationally, and he had Team Six experience, too, which was highly operationally oriented. That command atmosphere probably beneficially affected everybody, including the guys in the water.

INTERVIEWER: Oh, sure.

ADM. FLYNN: Again, I want to distinguish two things here. I don't imply any criticism. On the contrary, there's only praise for the guys who did the mission because they were given that mission to do. But from the point of view of coming up a few echelons in command, I think it was a dubious mission.

INTERVIEWER: I see.

ADM. FLYNN: The other mission, using SDVs, was the one on which Spence was killed.

INTERVIEWER: Oh, yes. Now, that was, I thought, just a decoy for a prisoner raid?

ADM. FLYNN: People were escaping from the prison camp and coming down the river. "Mokey" Martin, who lives here in town, was on that mission.

INTERVIEWER: Oh, yes.

ADM. FLYNN: Lt. Philip Martin.

INTERVIEWER: Yes. I know Mokey. Well, that's very interesting. There was a book written about that. Had you read that book?

ADM. FLYNN: No. I haven't.

INTERVIEWER: It's called *Operational Thunderbolt* or *Thunderball* or something like that. I've always wondered how accurate it was.

ADM. FLYNN: Then Maynard came over while I was in command of UDT Twelve in Subic. That was in 1968. He came over during the time Al Todd and others were doing something with SDVs and the USS *Greyback* and a fast surface boat. You ought to interview Maynard about what the heck that was all about, because they were going to do something in Vietnam, I think. Possibly, they were going all the way out to Korea to do it, but I think it was a Vietnam operation. But it was very tightly held, and I didn't ask Maynard what he was doing, but he came over to have a role in that.

INTERVIEWER: Why don't you, if you could, review the history of the development of SDVs?

ADM. FLYNN: All right. There was a number of Italian or foreign boats, such as the Trass boat. We had also SPUs, or swimmer propulsion units. Swimmers lay on them and steered them more or less by shifting the body. They had very limited range, and there was no protection for the swimmer. It was marginally better than swimming yourself, than relying on your leg power to get you through the water, but not very accurate with regard to navigation and the problem of what it did with this thing while you were in the objective.

INTERVIEWER: What year was this?

ADM. FLYNN: We had SPUs in the early 1960s. Then we had the Trass boat. Then, we had the Drut, which was built by a bunch of guys in Underwater Demolition Unit One in the diving shop.

Guys like Gionatti were involved with it. 'Drut' is 'turd' spelled backward. They actually built it with salvaged pieces of equipment and stuff. But they gained a fair amount of experience from it, and we thought that we needed better SDVs, and that was part of the swimmer support system. As I said, we wrote the OR for that in 1965, shortly after I got to the Pentagon. It included a six-man and then a two-man SDV.

INTERVIEWER: Let me read between the lines here and see if I understand this. The initial development was looking at boats and equipment that were out on the market and available by other people, other countries, and also some in-house development?

ADM. FLYNN: Yes. You could call it in-house development in the sense that there were engineers with blueprints. All of that was way above the actual level at which these guys did their best.

INTERVIEWER: I understand. Really, that laid the ground work for the formal plan?

ADM. FLYNN: Right.

INTERVIEWER: What was it called?

ADM. FLYNN: It was called 'Code 3802.'

ADM. FLYNN: Specific operational requirement, SOR, 3802, swimmer support system. It had in it navigation, SCUBA, the mixed-gas SCUBA, underwater communications, and the SDVs.

INTERVIEWER: That was the program that led to the successful development of the Mk-7, which was really the first practical U.S. Navy underwater vehicle?

ADM. FLYNN: No. The Mk-7 was before that. We started 3802, and it was a fairly long, cumbersome thing of doing research and development with a contract with Aerojet. It had to go through budgetary hoops and everything.

In the meantime, a Warrant Officer who was part of Underwater Demolition Unit One, said, "We really need to rebuild some Trass boats, and we need money for that." Because the Vietnam

War was on, I got him the money. It was no big deal, but I was in Washington and got the money for this, put it through NAVSEA, and the money went to Convair. The Mk-7's were officially rebuilds and rehabilitations of Trass boats.

INTERVIEWER: Oh, so this was done then shortly before the 3802?

ADM. FLYNN: Yes. Well, it was done in parallel with it and much faster, so they built the Mk-7's very, very quickly.

INTERVIEWER: What year was that was occurring?

ADM. FLYNN: 1966.

INTERVIEWER: Then, 3802 came along and was looking a little beyond that.

ADM. FLYNN: The 3802 project was looking far beyond that to much longer range: 36 miles, 6 hours, 6 knots. You were going to need to have the advance SCUBA, the life support system, the heating systems. All of that was part of 3802.

In the meantime, Convair built a boat that was typical of all the boats we've had since, with a rigid aluminum frame with fiberglass sheeting over it, a hard tank and a soft tank around the midpoint, and fairly rudimentary controls.

INTERVIEWER: I recall that when I was in UDT Twelve, my view of SDV operations was that they were pretty kamikaze.

ADM. FLYNN: Well, here's the deal on those. There were two boats, the Seahorse and the Trass. In 1965, when I was going back to Washington, I went to see a fellow named Ken and said, "Tell me about these SDVs and stuff." He gave me a ride in the Seahorse. He would put a pinger out way ahead some place, and we would track in on the pinger. That was reasonably accurate, You'd know where you were, so you could put a stream of fingers behind you and steer a course 180 degrees away from them.

Well, that was pretty tricky on the way in, because your signal was weakening as you went away from it. How were you going to fix it? You were going to drop these pingers off on some sort of anchoring system. We really hadn't figured out all of that. But Ken said we had to have something to improve on that, and that was obvious. They built the Convair Mk-7's over there at the Convair plant in San Diego. We just built five of them initially, and we got those things going and then they proliferated. Other people came in and said, "We need to have more of these things."

Well, it wasn't worthwhile having very many of the Mk-7's. They weren't quite Kitty Hawks, but they certainly weren't DC-3s. I mean, it was much closer to Kitty Hawk than a DC-3, and much closer to Kitty Hawk than a P-51. We weren't even up to a World War I Spad in the evolution of where we needed to go.

INTERVIEWER: But your thinking was, "Well, let's get a faster program up and running while we're waiting for 3802 to come along?"

ADM. FLYNN: Yes. We wanted to get something going and parallel with them. I thought five of those things were plenty. By the way, I also thought that you needed very few automatic mixed-gas systems. When I was in NAVSEA, I was thinking of buying dozens of them. Dan Hendricks came in after me and decided that every swimmer had to have one. He brought hundreds of them.

INTERVIEWER: Oh, my gosh. That was an expensive buy.

ADM. FLYNN: It was an expensive buy, and it overwhelmed the teams. The logistics of maintaining those things was way over their heads. No one was giving sufficient number of hours in the water to be really proficient with them.

What you really had to do was concentrate and do that only. Instead, they were doing all kinds of things. Well, first they had to do PT. They had to do small arms, and then they had to do

land combat and all that stuff. People would get into the water with those things once a month, maybe, and that was no way to really understand how the gear worked.

A lot of gear would get knocked as being no good, but people just weren't familiar with it. They weren't given the chance to get comfortable with it. By the way, you would need to bend down full length because a lot of people didn't have the patience and endurance, absence of claustrophobia and all that, even in a group of SEALs, to handle that stuff. You'll probably find in doing your research that it's the same group of guys that show up again and again on those things because they're self-selecting.

INTERVIEWER: That's certainly true, and that's always a problem. Then, the Mk-7 seemed like such a good idea, but you wanted to make it a little better?

ADM. FLYNN: Well, no. We knew even when we were doing the Mk-7, we had already written the requirements for 3802, it had to go through a huge bureaucratic process. That was why Ken said, "Just give me the money to repair these things, these Trasses or Seahorses." He didn't repair them. With that amount of money, they built the first five Mk-7's.

INTERVIEWER: Then the Mk-7's got to be more loved than you had anticipated?

ADM. FLYNN: Right. Everybody had to have a lot of them, and you know how we navigated with those things - with dead reckoning. You had no idea what the currents were doing. You could do some missions since because were in very familiar waters, like San Diego or Subic. Probably, there were east coast equivalents where people knew what the bottom gradient looked like and everything like that. We were using them. "Gator" Parks was involved in that thing with Maynard. They were taking Tunney and going to do something in Vietnam. I suggest you talk to Maynard about what all of that was.

INTERVIEWER: Yes.

ADM. FLYNN: But little Al Todd of UDT Twelve had the SDV platoon. Those guys put in a lot of time in Subic Bay, just dead reckoning around and doing occasional stuff with simulated limpets and so on. We didn't have real ones. They did attacks and delivered scout swimmers and the like. It was pretty easy to do that there because you didn't have to wear a lot of rubber, and when you went ashore, you could go ashore naked.

Later, when we started using the boats off Korea, where you had to have a lot of clothing, if you were going to be inserted onto a shore, you had a whole lot of clothing to take with you. It was a real problem, because the clothing had a lot of entrapped air in it, and consequently, it was buoyant. I remember once when the crew was trying to submerge a Mark 8 SDV and being unable to do it because the clothing of the team that was going to be inserted onto the shore wouldn't sink. We weren't able to extract the air from it. Had they been able to power dive it down, that would have compressed the air and, all of a sudden, they would have had to compensate for a considerable loss of buoyancy quickly if they were in deep water. Then, when they were coming to the surface to put these guys off instead of being able to do it in a measured way, this air in the clothing would expand and they would be popped up to the surface faster than they wanted to be. By the way, that sort of stuff needs to be worked out with the ASDS, or they're going to have guys popping to the surface when they don't want to.

INTERVIEWER: Well, now, was the Mark 8 a 3802 product?

ADM. FLYNN: That was a 3802 product.

INTERVIEWER: That was really using the Mk-7 as a starting point in making it better?

ADM. FLYNN: Right. Now, we went initially to Aerojet, and Aerojet, instead of using the aluminum frame, wanted to put the strength in the structure. Part of the reason was that we gave them unrealistic weight requirements.

INTERVIEWER: I thought the aluminum frame was also a gas storage cylinder. Am I mistaken there?

ADM. FLYNN: You're right. You did carry air in those gas cylinders.

INTERVIEWER: You'd have to have cylinders in addition? You no longer had the frame?

ADM. FLYNN: Well, yes, but the whole idea was that you were going to be using a mixed-gas rig. Anyway, that got way overcomplicated, and it wasn't all Aerojet's problem at any rate. Ultimately, it was going nowhere, and I terminated the work with Aerojet and scooped up the remaining money, and Ken went up to China Lake and built the Mk-8 and 9 as we know them.

INTERVIEWER: That was no longer an Aerojet project. It was an in-house project?

ADM. FLYNN: That was done in-house at China Lake. We had the first runs of them done in Lake Isabella and a true Skunk Works. I doubt that there were a dozen people working on it. It was probably more like eight or ten whom Ken handpicked, like Frank Gorlic, Gator Parks, guys like that, guys who really knew how to do things. Some of them were still sailors.

INTERVIEWER: Frank Gorlic was one of my instructors.

ADM. FLYNN: He was a good guy, wasn't he?

INTERVIEWER: Oh, yes.

ADM. FLYNN: He was my leading PO in the fourth platoon in UDT Eleven. I could have gone home and just left him to run the platoon. He probably wished I had. But you're starting to get a lot of capability into it. For one thing, you've got the forward-looking sonar, which, by the way, we had started to use in the Mk-7, retrofitting an obstacle avoidant sonar. The obstacle avoidant sonar allows you to pick up underwater topography, particularly in San Diego. It shows very clearly the side of the dredged channel. It shows up remarkably, so you can follow the side of the dredged channel all the way into the carrier pier or down to 32nd Street. I think if you were ever going to

do a real operation on it, you'd have to do some probes first and figure out what the underwater landmarks are.

(Whereupon, the PROCEEDINGS were adjourned.)

IN ON UNDER AND ABOVE THE WORLD'S OCEANS

- # -

THE OCEANOGRAPHER AND THE NAVY

Rear Admiral J. Edward Snyder, Jr., USN (ret)

September 2003

INTERVIEWER: I would like to focus first on your term in the Office of the Assistant Secretary of the Navy (ASN). Were you his aide or his assistant?

ADMIRAL SNYDER: Well, let's go back to 1963. I was still a commander when I reported to that office, right after the USS *Thresher* disaster. At first, I was the special assistant for surface, but I held other titles later as the secretaries changed. Dr. Jim Wakelin hired me because the aide and executive assistant to another assistant secretary was a former commanding officer.

Although he had given me an almost unsatisfactory fitness report when I was his executive officer, he recommended me when Dr. Wakelin said he wanted an iconoclast, someone he could trust to tell it to him like it was. When I first came to the office, I told the assistant secretary that I really didn't want the job because I had been selected for command of a guided missile destroyer. I was coming from the command of a World War II destroyer. I was also concerned because during my research and development experience within the nuclear weapons program, I had not had the necessary two years at sea in command. I needed another three months. I think that the *Thresher* went down in April and my two years would have been up that June. Dr. Wakelin agreed to do something that was probably quasi-legal. He said okay, "I will have BUPERS order you here on temporary additional duty from your destroyer to the chief of the bureau of supplies and accounts. But you will work in my office." That worked because my ship has just gone into the Philadelphia Naval Shipyard for a FRAM, which was a two-year program. It was not a real problem. That was how I got started up there.

INTERVIEWER: The record I have reads that Dr. Wakelin had been the Assistant Secretary of the Navy since June 1959.<sup>1</sup>

ADMIRAL SNYDER: My memory is that he took on the title of ASN for research and

development probably the year before I arrived, in 1962. Maybe they changed the title while he was in the office. The previous title had been 'Assistant Secretary of the Navy for Air.' Theodore Roosevelt had been the Navy's assistant secretary before he became president. He must have had a low opinion of aviators because he is recorded as saying that the Navy should buy one airplane and let the damn aviators take turns flying it. Franklin Roosevelt was also an Assistant Secretary of the Navy from 1913 to 1920 in the Wilson Administration and during World War I. Admiral Moorer had, at some point, been the executive assistant to the ASN. When he was the chief of naval operations (CNO), he used to kid with me that my boss was senior to him. I would always take the CNO's flag with me when we would go on a trip. If the CNO were there, I would insist they fly his flag. He, in turn, would always tell me to take his flag down and put up the secretary's flag, so I would carry out his orders. But it was interesting because that was how I learned that Admiral Moorer had been in the circuit.

INTERVIEWER: If Dr. Wakelin was appointed in 1959, Eisenhower appointed him. You arrived in the Kennedy administration and he was still the assistant secretary at that time. What was his background?

ADMIRAL SNYDER: We could verify that with a call to Steve Anastasion, who was the guy I relieved. I'm 99% sure that I'm right because we didn't have research and development (R&D) in the military then. Steve became special assistant for surface when that office was set up. They created the DDR&E position, or Defense Department Director of Research and Engineering, simultaneously with establishing the assistant secretaries for R&D within each service. Dr. Herbert York, a guy with whom I worked at Lawrence Livermore Lab, became DDR&E when that office was first established. The first couple of guys all came from Los Alamos at one time

or another, and that was when the DDR&E was number two in the Department of Defense (DOD). That is, there was a secretary of defense, and right under him was the DDR&E. I don't know how that all happened because I'm not a good historian. I never really looked into why. Congress must have done it because you can't shift titles like that at the DOD level just because you want to do it.<sup>2</sup>

That was interesting because they did not increase the number of presidential appointees in the service departments, the Army, Navy or Air Force. They substituted, at least in the Navy. Dr. Wakelin's title may have previously been 'Assistant Secretary for Air.' It was President Eisenhower who had the Navy form the first equivalent of the Interagency Committee on Oceanography. I don't think there's ever been a history of the Office of the Assistant Secretary for R&D. I knew nothing about the Pentagon when I arrived. It was my first time in that establishment. Dr. Wakelin had agreed that I could first go back to my ship before reporting in. When I did report a couple of days later, he greeted me with a 'publication,' which was something I had never seen before, called "The Seahawk Destroyer - Technical Development Plan (TDP)." He said, "Eddie," and he was the only person to do so, but he always called me 'Eddie,' "Take this home tonight and tell me tomorrow what you think of it." I always knew when he was on the phone because no one had ever called me that, including my own father. I came in the next morning and had written with big, black crayon pencil, "TDP = Trash Developed Profusely." He laughed and said, "Well, you're certainly living up to your reputation." Wakelin was quite a gentleman. His first name was James. Everybody in the E Ring except for me, who always called him 'Mr. Secretary,' called him 'Jim.' He had a relatively good sense of humor but was truly a gentleman. His only real objection to me was a repeated and consistent

admonition: "Eddie, you have to calm your mouth down. The words that come out of it are not really CC." I always replied, "Well, Mr. Secretary, what do you expect in Disneyland East?" That was before Disney built their place in Florida. I had written a paper at the war college called "The Five-Sided No-Sayer." I have unfortunately misplaced it. I was looking for it the other day. But I'm getting off track. You're going to have to keep me going.

INTERVIEWER: You said your background was nuclear. Is that in nuclear weapons, not in propulsion?

ADMIRAL SNYDER: That's correct. I was never in propulsion. I had been aware of propulsion. In fact, in approximately 1950, during the early part of the Korean War, before I went to the Massachusetts Institute of Technology (MIT), I was stationed at Los Alamos and had put in a request for assignment to the first nuclear powered surface ship. I had a specified assignment in or about 19xx, something or other, by which time I would have made lieutenant commander or commander. That was in my service record when Admiral Rickover interviewed me for possible command of the nuclear destroyer USS *Bainbridge* or for executive officer (XO) of the cruiser USS *Long Beach*. He rejected me for those jobs. He brought it up by saying, "Who on earth did you think you were that you knew so much that we were going to have one in this time frame?" I had been very respectful. He was only the third flag officer I'd ever met in my life, but that's another issue. I do remember that the last question, after he'd gone through all the items from his standard Rickover treatment, usually was, "What did you do, spend all your life in bed, because you have five children?" But I only had two children. His comment to me was, "Why do you need a Ph.D.? Why did you want to go to MIT? I don't have a Ph.D. I go to Los Alamos any time I want to." I said, "Well, sir, I'm not an admiral and I'm not really the father of nuclear power. As

a kid, I had always wanted a Ph.D. in nuclear physics." I could tell the interview was coming to an end and he looked at me straight in the eye and said, "Who do you think you are, Jesus Christ?" I said, "No, sir," and was dismissed. I walked back to the house of my first classman Reuben Woodall, where I was staying overnight, and he told me, "Ed, if you had said, 'there can't be three of us, Admiral,' you'd have been in like Flynn." I always remembered that and it kept me in the Navy. I was ready to go back to BUPERS and quit, resign. All my life I had wanted to do this. I really felt that nuclear power would be important in the Navy.

INTERVIEWER: For the record, you're the son of a pastor?

ADMIRAL SNYDER: Yes, I am the son of a Methodist minister. I never did get my Ph.D. from MIT. I stayed there only two years. I was accepted by MIT for a Ph.D. in nuclear physics. I had written part of my dissertation and they accepted the topic. But the Navy wouldn't let me stay. There were three or four of us going there at the time and we all had to come back into the Navy. One of us, Reddie Cobb, who was a little bit younger than I was, went back about four years later. I don't know whether he had had to change to specialist restricted line or what, but he came back and finished his Ph.D. MIT took my paper as a thesis, didn't make me go any further, and granted me a Master of Science degree in physics.

I was bitter about that, but I also realized that I was in trouble. I was a lieutenant at that time and I think the thing that saved me was that the professor of naval science at MIT turned up as a Navy captain on my selection board. I thought I would be passed over because I had spent too much time in school, meaning a year and a half at that time. When the captain came back, he told me what had happened. He said that the Navy had to have people in graduate training. He didn't happen to have a graduate degree but was watching what was happening to his Navy

officer graduate students at MIT. He thought that the Navy ought to look at their records and not worry about whether they were spending too much time getting educated unless they thought they were not proper naval officers. He said, "You made it, but boy, it was a by the skin of your teeth sort of thing." That taught me a lesson. I also wanted to get out of Los Alamos because of that. But you didn't realize the importance of it to the Navy. I had always thought that the Navy liked graduate education. They had set up the Office of Naval Research. I thought they would support education. But it turned out that the unrestricted line in the Navy had not been very receptive. I'm probably very close to being unique, as someone who has commanded three or four ships and also been in charge of significant R&D programs.

INTERVIEWER: Your later career points out that you were aware that there are communities in the Navy, officer communities, that get lost, isolated, and forgotten, but I'll come back to that later. Did you make lieutenant commander on time?

ADMIRAL SNYDER: No. I could not because of lack of sea duty. I got back pay when I did. When I left MIT, I reported to Doug Plate, who is still alive, I am sure, who was a commander and skipper of the destroyer USS *Edward F. Larson*. I was his XO. But he absolutely resented the fact that one, he had a lieutenant for XO when everybody else had a lieutenant commander and two, I was an egghead coming from MIT. I used that as a pretext, when he was sailing to the west coast, to get transferred as XO to another east coast destroyer. After I had gotten in my time at sea, I got the rank of lieutenant commander and considerable back pay. Since I had retained the same date of rank as those on the earlier promotion list, when I did put on the gold leaf, I got enough back pay to buy a 1957 T-Bird, which got Mary Louise uptight.

INTERVIEWER: Tell me about coming to the Pentagon and Dr. Wakelin's office. You said it

was right after the loss of the *Thresher*. Wasn't it true that the loss of the *Thresher* made possible a lot of what people had been hoping to accomplish and triggered the foundation for the very successful Navy ocean program whose inception dates from about that time?

ADMIRAL SNYDER: I would have to agree with you. I would have to say, to go even further, that we wouldn't have had oceanography anywhere other than in the Office of Naval Research or the Naval Research Lab had it not been for Dr. Wakelin. His background was Ryan Aviation, I think. He was a Ph.D. and academically inclined but also a great gentleman. It was probably the best thing that could have happened. There, you had somebody coming into the Pentagon after the establishment of DDR&E. You had a separate line appropriation for research and development and a Navy assistant secretary who was skilled in that area. I knew absolutely nothing about research and development from that standpoint. I knew how to manage programs but not how you did it in a bureaucracy. I had just finished writing this paper about how there were so many admirals in the Pentagon and that they were all no-sayers. You could never get anything through and that was why the title of the paper was "The Five Sided No-Sayer." Dr. Wakelin was impressed by my "Trash Developed Profusely," although TDPs were part of the new McNamara system on how you did paperwork. Nobody cared about whether you had a destroyer, but you had to prove in the paper work that it was cost effective. We were off to a good start in that sense, except for my language, which he continually criticized. My office was, by the way, closer to his office his executive assistant's office. I was right outside his door and the executive assistant was in a little cubicle behind it.

INTERVIEWER: The executive assistant was uniformed?

ADMIRAL SNYDER: Yes. He was a captain. In those days, one of the fascinating things, which

I can go into later, was that the Navy, though I can't speak for the other services, refused to have deputy secretaries, deputy under secretaries or deputy assistant secretaries. They had naval aides and executive assistants. They were four-strippers. All of them were four-strippers and the people who controlled the calendar. In fact, the CNO and vice chief didn't have civil servants to help them. They each had an executive assistant and a naval aide. When Admiral Kidd was a captain, he was naval aide to Admiral Moorer. Dr. Wakelin, the Assistant Secretary for Research and Development, for some reason or another, of which I do not know the real origin, absolutely felt compelled to do something about oceanography. It was Dr. Wakelin who put money in the budget to create all these new oceanographic institutions. I don't remember how many we had in 1962, but I think there were Woods Hole, Scripps, Texas, and Columbia. Columbia was the one that did bottom contour mapping with Iselin or somebody who was very famous, up on the east coast. By the time I left, the office had something like 15 new programs in academic oceanography outside of the military. We had no oceanography within the Navy until after I left. When I came back, I found that the oceanographer was in charge of the oceanographic program at the postgraduate school in Monterey and of supplying ships and faculty for the program in oceanography at the Naval Academy. That was Dr. Wakelin's definition of oceanography.

INTERVIEWER: That was initiated after you left the office?

ADMIRAL SNYDER: It was in the process of being done. I was trying to get it done. I was there for almost five years and thought it was absolutely ridiculous that you had the Assistant Secretary of the Navy running the Naval Academy. Those are my words. I would have thought the CNO would be involved. Up until that time, we had never had anybody who was interested in research and development. We might have had past Navy admirals or captains who were

interested. In fact, you're aware of many of them who were. However, there was no formalized Navy structure for research and development. As a matter of fact, since I had no knowledge of how you did things within the bureaucracy of the Navy, I decided that I would learn. I asked the secretary if I could have his authority to write a pamphlet called the RDT&E Management Guide, or in other words, the "Research, Development, Test, and Evaluation Management Guide." He said, "Fine, Eddie, go do it." I called people. By that time, I had been introduced to civil servants in all the bureaus and to all the flag officers in the Pentagon. I had learned because of my own negative experience with flag officers that you did not get them involved with anything. I called over to various bureaus, the Office of Naval Research and the Naval Research Lab and arranged for designated GS-15s or above to come on over and sit in my office so that we could talk about what it was they had to do. To make a long story short, we wrote the manual. You have to realize that at that time, none of the uniformed Navy or even the civilians really understood formal research, development, test, and evaluation because it was only a little more than a year old. I wrote in the first edition that the Assistant Secretary of the Navy for Research and Development was the program sponsor and appropriation sponsor for the expenditure of RDT&E funds. When I left the Pentagon, the chief of naval operations still believed that the Assistant Secretary for Research and Development actually decided where that money came from, who got it, and where it was going. Nobody questioned that while I was there. DDR&E didn't question it. It was actually not true. Nobody in Congress ever even said anything about an appropriations sponsor. That indirectly gave him and his two successors immense power, if you stop and analyze it. I remember Dr. Wakelin saying, "Eddie, we don't have enough good officers being sent to these Navy labs. As long as we're going to have Navy captains running these

laboratories with one top civilian, don't you think we ought to find people who really qualify?" I said, "Absolutely," so he told me to go find some. I found some and he had me call the Bureau of Naval Personnel. I said, "The Secretary wants Captain so and so sent over to Dahlgren," and they did it. Dr. Wakelin's executive assistant at that time was Captain Moran, who was later as a vice admiral in charge of OP-07, the research and development office. I remember that because Wakelin was on a trip with Moran after I had mentioned I had worked with Captain Hassler, an ordnance specialist. Command of the Dahlgren lab was coming open, so I was told to call Captain Hassler. He remembered me, so I said, "Sir, would you be willing to take on Dahlgren and see if we can get it in good shape?" He said, "Let me think about it," but called me back in about thirty minutes and said yes. I had them cut a set of orders for him. When Wakelin came back from his trip he said, "That was great, Eddie." Of course, the aide who was a naval aviator got really uptight that we had put a non-unrestricted line officer in an ordnance laboratory. Those kinds of things were not being done.

INTERVIEWER: Was he a restricted line ordnance specialist?

ADMIRAL SNYDER: Yes, he was assigned to ordnance engineering duty. He came to mind mainly because I knew what he had done in the Polaris program and how competent he was. Now, that was an unfair thing to do. I should probably have looked at every one available. But the first thing I wanted to do was to be sure we had a specialist there, an ordnance duty only, and there weren't really that many qualified four-stripers. I knew quite a few of the ordnance specialists because they had been working in the Polaris program under Admiral Raborn. In fact, that was where Hassler came from. Anyhow, that allowed the Assistant Secretary for Research and Development to appoint the commanding officers of Navy laboratories, in fact. It allowed

him to create the title 'Director of Navy Laboratories.' It allowed him to do a lot of things because nobody understood what was going on, but Secretary Wakelin was not a power grabber. He was a real gentleman. I say that was important at that time because there were a lot of feuds and fights going on. Secretary Wakelin never got excited about that. He'd go over and smooth over the waters. He'd even get Admiral Ramage, the head of submarines, to calm down. They had been together previously at some point. He had warned me. Ramage was the only admiral that I wasn't told to go visit when I reported aboard, Red Ramage, Medal of Honor recipient, head of submarines.

I don't know why, but Dr. Wakelin just told me you don't get involved with him, period. It turned up later when we created the thing in which I'm sure you're interested. Admiral Ramage felt that when a ship went down, when a submarine went down, that was a grave! Don't touch it. He really got ticked off when we went to look for the *Thresher*. The first thing I was ordered to do was to get involved immediately with the Deep Submergence Systems Review Group (DSSRG). It was actually a SECNAV technical advisory group looking into the background of the *Thresher* disaster. It was not the board of inquiry that asked why the *Thresher* went down. It was a group that he formed to find out what we should do so that it did not happen again and suggest a technical plan. That was the Stephan committee.

INTERVIEWER: Where was the new Director of Navy Laboratories assigned?

ADMIRAL SNYDER: He was over in the materiel side, initially. He later came over into our office, the secretary's office, but he was originally established in the materiel side of the house. At that time, the secretary of the Navy ran the materiel side of the Navy. A lot of people don't know that but at that particular time, the Secretary of the Navy was legally in charge of the

materiel establishment. In fact, I had been involved with establishing the office of Chief of Naval Material. It took many months to get the piece of paper written that established the Chief of Naval Material as a four-star admiral. The Navy didn't like that idea. The final compromise, at least as I saw it, and remember that I was a pretty junior commander, was that if the Chief of Naval Material was an unrestricted line officer competent and qualified in program management. That would keep the blue suit Navy in the Pentagon relatively happy. You've got to remember that if you put four stars over there, you were taking them away from somewhere else.

INTERVIEWER: NAVMAT came under OPNAV?

ADMIRAL SNYDER: No. At that time, NAVMAT reported directly to the Secretary of the Navy, legally. There were lots of innuendoes, but legally, we had just established the Chief of Naval Material under the Secretary of the Navy. Under the Chief of Naval Material came all the old bureaus that were to become the SYSCOMS. One exception was the Office of Naval Research. In accordance with a nice, little title ten code, the Secretary of the Navy could appoint the Chief of Naval Research from any person in the Navy or Naval Reserve, commander or above. When appointed, that officer would be a rear admiral upper half with two stars while serving. The CNR reported to the Secretary of the Navy. But the Secretary didn't want that, so he said, "Since I've got this new Assistant Secretary for Research and Development, report to him." That was wonderful because the Office of Naval Research had a comptroller. ASN(R&D) had its own comptroller. The RDT&E management book then stated that the comptroller for the appropriation RDT&E Navy reported to the Assistant Secretary of the Navy for Research and Development. You wired all that together and that was how you were able to get billets.

I don't know how this happened. Maybe you can find out. We had had trouble in the

1950s getting good civilians to come work for the Department of Defense. A new law called Public Law 313 permitted the secretary of the services, and in those days we weren't really that joint, to pick those who had the academic background in certain subjects such as physics, chemistry, mathematics and the hard sciences, and automatically appoint them as PL-313s. That paid them at the top of the pay scale. It was not the old GS-16, 17, and 18 system but a new establishment called 'PL-313.' That was their code. They weren't 16s but they were paid as 16s. In fact, I was shocked. I found out when I looked into it, in trying to get everything organized, Dr. Wakelin was getting \$20,000 a year, GS-18s were getting \$20,000 a year, and PL-313s were getting \$20,000 a year. I thought, "Boy, there's something wrong with this system." The CNO was getting \$20,000 a year. Of course, the CNO had certain perks and at that time, the assistant secretary had a few perks also, such as a car and driver. It was all tied to how much a congressman was getting. I don't remember the formula, but that formula hasn't changed, to my knowledge, in fifty years. What I mean is the formula as to who can get paid compared to whom.

That isn't strictly true. I remember very clearly a stunt we pulled in Hawaii. When we wanted the University of Hawaii to get into oceanography, John Craven was willing to go there when he was ready to retire from the Navy. The law in Hawaii was that you had to be a resident of the State of Hawaii for ten years before you could be a part of the University of Hawaii. We managed to get around that in the case of Dr. Craven. I am not sure that John Craven will agree with me on that, but I remember. What we did was establish, as had been done out in Texas, a separate institute that was not part of the university but parallel to it. That way, it didn't come under the same law. That was the reason we had lawyers. You remember that we had lawyers in the Office of the Oceanographer. I remember telling our own lawyer, "Don't tell me what I can't

do. You're only paid for one thing. Tell me how I will have to do it to get it done.” That was what we did in the E Ring. If a law was an obstacle, you tried to figure out how to bypass it. That was important to get things done, as long as you had a gentleman and an honest man as the assistant secretary. In fact, Dr. Wakelin put much emphasis on Admiral Stephan's group and on oceanography. He had me define oceanography. Not knowing anything about it except what I had learned in the Polaris program, I just defined it as all the research, development, test, evaluation, and operations necessary for the Navy to operate in, on, under or above the world's oceans. That was a broad cotton picking thing, and it got somebody mad. I think you know who first got mad, the Supervisor of Salvage. The secretary was basically saying that anything that goes on in the ocean was part of the Navy's mission and was oceanography. It really wasn't, of course, but it took us two assistant secretaries before we actually got Secretary Nitze to sign the instruction that made it so.

The big holdout was the submarine force. It was Buck Dietzen, a classmate of mine, who was running submarines by that time, out of OP-03 or 31 or whatever, and he resented the fact that he was going to be the Assistant Oceanographer for Ocean Operations. I think with your background, you can understand the animosity that a nuclear submarine officer had toward that kind of stuff. Whether it was because of Admiral Rickover, I don't know. I don't the inner details. The only way I got involved was when I had been about three years into my job and the Office of Naval Research put something on the E Ring wall, right outside Secretary Nitze's office. It was put there by Admiral Claude Ricketts, the vice-chief, who later died of a heart attack in his doctor's office in the Bethesda Naval Hospital. It gave ONR and a couple of Navy

scientists (Philip Abelson<sup>3</sup>) the credit for being the fathers of Navy nuclear power. I remember that Admiral Rickover sent for me and wanted me to get rid of that. I think the same problem showed up in diving over the question of whether ONR was really running anything. One has to recognize that, under the rules that were set up, the Office of Naval Research had no authority to run any part of the operational Navy. The only time they did get that was when they reported as the Assistant Oceanographer for Ocean Science. The Oceanographer, as an unrestricted line officer working also with his CNO hat (Assistant Oceanographer for Operations), could direct them to do something.

INTERVIEWER: There were some problems with SeaLabs I and II?

ADMIRAL SNYDER: Well, there were problems with all of that, but I'll go back to Wakelin because I call him the 'Father of Naval Oceanography.' When he was a lieutenant or lieutenant commander in World War II, he was one of a group working in naval research. I don't know that he understood it scientifically, but he realized that the ocean was important to the Navy and that we better understand it. We better be able to have our capability, he realized. The Stephan group (DSSRG) began to show the kinds of things that needed to be done in order to give us that capability, including diving, which was not an insignificant thing. You've got to realize that Wakelin liked diving but I don't know why. Before Dr. Wakelin came to the Navy, he ran a research group in the National Geographic magazine hierarchy. I can't remember the exact title. National Geographic had given Cousteau a sum of money, possibly \$25,000, to purchase an ex-French navy vessel that he then named the *Calypso*. It wasn't Navy money. It was National Geographic money from the Wakelin office, before he became assistant secretary. Dr. Wakelin showed an interest in oceanography when he was with the National Geographic, before he came

to the Pentagon as ASN(R&D).

Dr. Wakelin told me to get in touch with Captain Cousteau, as he wanted to have lunch with him. I can remember that for one particular reason that Captain Cousteau probably didn't understand. He brought Mrs. Cousteau with him. At that time, I don't think he went anywhere without her. She was keeping him under control, in my personal opinion. Anyhow, she showed up and that tore the E Ring apart, of course. There had never been a woman guest in the Secretary of the Navy's mess. All of a sudden, we had a formal luncheon at which the guests of honor were Captain and Madame Cousteau, with Wakelin hosting. The Secretary of the Navy was also there. I was there. Cousteau made a proposal in front of the Secretary of the Navy and whoever else. He said that we needed to get involved in man's exploration of the ocean and the ocean's power. Captain Cousteau was going to help us.

INTERVIEWER: What date was that, approximately?

ADMIRAL SNYDER: Well, it had to be before Kennedy died, because Wakelin left after that. I was at the White House the day Kennedy was assassinated and I remember that less than X number of days later, we were told by the White House aide that Wakelin was out of a job. When President Johnson became President of the United States, he chose to get rid of all appointments within the Defense Department, with the exception of McNamara. The Republican President Dwight Eisenhower had appointed Dr. Wakelin. Kennedy was in office from January 1961 to November 1963, The Thousand Days, two and a half years, almost three years. I don't know whether I had been at the Pentagon for a year. Wakelin had a background with Ryan Aeronautics, so it made sense that a Ph.D. with an aeronautics background would be the assistant secretary in the office previously known as ASN for Air. Eisenhower appointed him in 1959.

His title may have been changed from Assistant Secretary for Air to Assistant Secretary for Research and Development. I'm not certain when that occurred because it was before I arrived. Steve Anastasion or Bob Abel should know something about that, as I inherited both of their jobs.

INTERVIEWER: The departure date of 30 June 1964 may have been just the day before Dr. Morse arrived on 1 July 1964. Could there have been a gap with no incumbent?

ADMIRAL SNYDER: There was a hiatus at that time and the reason for it was unforgivable. We all knew that a Republican had appointed Wakelin. Kennedy had decided that even though a Republican appointed him, Dr. Wakelin could stay on if he was doing a good job in research and development. Kennedy put his poker-playing buddy in as the Undersecretary of the Navy. I remember that really clearly because he had a playmate of the year. Red Fahey from San Francisco played poker with the President of the United States one day a week. The Navy let him alone. He certainly had no other capability whatsoever that I could see, and I knew him very well. Those were the days when the secretary had a lot more power than today. Without the secretary, or without McNamara, you couldn't get any money. Let's put it that way. You had to kowtow to them a little bit.

INTERVIEWER: One of the things that is of interest to the diving community is George Bond and the SeaLab, and that happened before Wakelin left. I remember you telling me that you were the one who wanted to get a briefing for Dr. Wakelin about the Navy Medicine program in diving. As I recall, you said that the Surgeon General then sent Captain Bond to do that briefing. Do you remember anything about that?

ADMIRAL SNYDER: Well, yes and no. It was absolutely true because Wakelin had Captain

Cousteau over to get involved with diving. It had nothing to do with what you and I would have considered scientific oceanography at the time. He wanted to have an 'inner space program,' as we called it. It was Senator Warren Magnuson who led the crusade, if I can remember.

Magnuson was as crude as I was and always drunk. I can remember that he said, "We know less about the ocean's bottom than we do about the moon's behind." Wakelin and Magnuson were very close friends. One of my jobs at parties was to keep Magnuson happy, but not drunk. That was an impossible task in those days. I didn't know the word 'alcoholic,' but maybe he was an alcoholic. He sure liked to imbibe. Let's put it that way. He drank a heck of a lot. I always went as the aide when we had an ocean function because the naval aviator would handle all the other things. But Dr. and Mrs. Wakelin always wanted me to come along because I was their Special Assistant for the Ocean's Bottom. Although my title was for surface, I spent at least 45 hours a week on oceanography, which included diving at that time. That was why he had Captain Cousteau over. Wakelin had in the back of his mind, as we have discussed, the need to have a program that would be, and these are my words, a poor man's space program. The assistant secretary indirectly sponsored the Bureau of Medicine and Surgery, and we were also trying to convince someone to do surgery underwater in pressurized chambers. We were doing this also through the Interagency Committee on Oceanography (ICO), which at that time included a rear admiral upper half from the Public Health Service as a member. Abel would know more about that and when it was formed, because I just inherited the responsibility. It also included the Bureau of Commercial Fisheries and all these other ocean agencies. When the Bureau of Commercial Fisheries reported to the ICO that they were having money troubles and would have to get rid of all their ships, Wakelin said, "I can help. The Navy needs to get some information

about the oceans. Eddie, you go get some money and transfer it over to the Bureau of Commercial Fisheries so that they can operate their ships.” Now, if you try to do that in today's world, or even when I came back as the oceanographer, you will be court-martialed. But we did have the authority to do that back then. We had the 6.1 money and could move it around.

Bob Abel was the executive secretary for the ICO as a civil servant. He was also the guy who directed the National Oceanic and Atmospheric Administration's (NOAA) Sea Grant Program, and was recently the president of the Marine Technology Society (MTS). I haven't seen anything from MTS. I'm trying to get rid of all my stuff. I did see that pin or something they gave me for being an honorary something or other for their technology society.

INTERVIEWER: Did Senator Magnuson have a specific interest in diving or just give general support?

ADMIRAL SNYDER: He had an interest in understanding the ocean. My comment always was that you could not understand the ocean unless you were able to put men down there to look at it and put equipment down there to work in it. Magnuson fully supported that. It may have originally been based on the commercial fishing interests in Oregon, but it never came to my attention as such. He was a big sponsor of oceanography with that statement about the moon's behind and was a pretty powerful guy in the United States Senate. He was leading the charge then. It was not Senator Russell. Russell was a powerful man also. Russell was head of appropriations full committee, as I remember it, and was head of the armed services subcommittee, which gave him one devil of a lot of power over the Navy. The guy who relieved him was Senator Stennis, and I remember that Senator Stennis was the last person to ever hold both of those jobs. After that, I think the Senate began to realize that those positions were a little

bit more powerful than they should have been. Let's put it that way. I don't really know, because I wasn't in the Senate's inner circle. A lot of people respected Senator Magnuson. Also, at that particular time, you had Senator Hollings. Now, you tell me why Senator Hollings would be interested in oceanography. But Senator Hollings was, in reality, our east coast supporter of oceanography.

We were looking for words to put the same kind of public emphasis on our inner space program that National Aeronautics and Space Administration (NASA) had for its outer space program. Do you do it remotely or do you do it with man? The Deep Submergence Systems Review Group had recommended both. Like all good scientists, we never had enough. We hadn't studied it enough, so we needed both Man in the Sea and remote sensors in the sea. Wakelin was looking specifically at the business of putting man in the sea, and somehow or other through the ICO or things like that, he was also aware of Ed Link's work. Ed Link had been acquainted with him in the past. Wakelin's background was in aviation, so they might have met through that or possibly through the connections they both had to the National Geographic. But Ed Link was involved. Dr. Wakelin put him on the DSSRG. We were trying to look at how we could get people excited about the oceans. One of the ways of getting them excited was, of course, through the Bureau of Commercial Fisheries' interest in feeding the world's population with fish. Everybody had his own ax to grind, but Wakelin decided that, irrespective of my recommendation to him and of the cost of putting man in space versus the remote, we would follow the space program and somehow or other we have a manned diving program. I don't remember who invented the word, but it would be called 'SeaLab.' The reason it was called 'SeaLab' was because we were doing this through the Office of Naval Research, as that was the

only legal way we could get a new program started. We had the concurrence of the Senate. We also had support from the House of Representatives. I can't remember the house members who were supporters of it, but it was in a subcommittee. Oh boy, my mind is boom, boom. I wish I could remember, because we took all of them on a flight to show them Scripps and all the other labs. From that, we got lots of supporters, including, I think, the congressman from Michigan, who may still be in the Congress. I remember riding in the plane with him and we were talking about its importance. To me, it was absolutely fabulous to realize that we had supporters from places like Michigan who maybe had a lake but didn't know what the word 'ocean' was. They were interested in Detroit and automobiles, but you had those gentlemen really believing that it was a great program, that the United States really needed to do something about it. We were trying to get something started in the manned side of the program. You know better than I do that we had a lot of those programs run by the Bureau of Medicine and the Supervisor of Salvage and so forth. But Wakelin had a broader concept and would say, "Eddie, we're going to do this like the space program. You go get Scott Carpenter. If we can put him in the SeaLab, then we're going to have a program that will get us some attention. We need attention to get more support from Congress so that we can get the program financially sound," or words that he would use. I don't remember what they were, but they basically meant you could not have a program without people and you could not have a program without money. The problem was getting the people and the money.

INTERVIEWER: Do you remember the invitation to George Bond to brief SECNAV? Did he brief Dr. Wakelin or the secretary?

ADMIRAL SNYDER: He briefed Dr. Wakelin. I don't remember whether the secretary was

there, but I seriously doubt it. We're talking hours of briefing, because Dr. Wakelin could get carried away, as you and I are getting carried away now, and talk for hours. The Secretary of the Navy can't do that. But that was Dr. Wakelin's personality. He was a gentleman, but we were going to get through the program and we were going to understand it. Those are my words. He was using Captain Cousteau, and nobody used Captain Cousteau. Captain Cousteau used other people. But Wakelin thought he was using Captain Cousteau to get the Man in the Sea program moving because the French had already done it and that was how Dr. Bond came in. I didn't know him personally. I had met him and was impressed by him, but I didn't know anything about medicine. These new subjects could easily impress me. My background was in hard physics. It wasn't biology. I couldn't understand what the medical problems were but knew that you had to have people. In those days, the people who really understood man's ability to survive in the ocean were, in fact, in the Navy under the Bureau of Medicine, and that was where Captain Bond came in.

INTERVIEWER: As a matter of protocol, the invitation went through the Office of the Surgeon General. Is that correct?

ADMIRAL SNYDER: Yes. Secretary Wakelin didn't own the Surgeon General, but he was, in my opinion, the SECNAV sponsor of the Bureau of Medicine. The Surgeon General was always responsive to us, and in general, his contact was through me to the Assistant Secretary for Research and Development. Again, you had the assistant secretary for R&D running what I call 'outhouses' that nobody else cared about, like the Naval Academy, the Postgraduate School, the Bureau of Medicine and Surgery, and he was also involved in the Bureau of Supplies and Accounts. That was because of me, trying to figure out how we could tie together logistics, spare

parts, and readiness, because his title was not just R&D. Dr. Wakelin's full title was Assistant Secretary for Research, Development, Test, and Evaluation. That meant that you had OPTEVFOR, or Operational Test and Evaluation Force, the group of people under the CNO who took a new program and checked it out at sea. Well, of course, when we didn't want to do that, like in the diving program, because we knew we'd run into all kinds of bureaucratic problems, we ran the operational programs through the Office of Naval Research. That really wasn't right, and may be why we had some problems with the Man in the Sea program. To copy the space program, we first called it the 'Man in the Sea program,' and that was where we were trying to use Captain Cousteau's influence to accentuate diving, along with using Ed Link, Perry and several other people. There was quite a bit of development going on long before I got in the program, led, I thought, by the French submersible development and by what other people called 'toys to play with in the ocean.' Wakelin's concept was that those were not toys. They were necessary for the Navy in order to ensure that its submarine force could be handled safely. Now, Admiral Ramage, who was head of the submarine force, was absolutely uptight as heck with Dr. Wakelin and me over the issue of going down to look at the *Thresher*, where we took the *Trieste*. Remember that we had the *Trieste*, so we weren't completely new at developing research vehicles. The bathysphere *Trieste* was, in fact, brought around to the east coast to look for the *Thresher*.

INTERVIEWER: Was Dr. Wakelin the SECNAV sponsor for the deep *Trieste* dive in the Mariana's Trench by Don Walsh and Jacques Piccard?

ADMIRAL SNYDER: I don't know. You'd have to ask Don. I don't know who sponsored it. I remember Dr. Wakelin saying he was amazed that it was President Eisenhower who had him

form the Interagency Committee on Oceanography. The President of the United States, Dwight D. Eisenhower, started it. Maybe Steve Anastasion knows. Things had been going on a lot before I even got there. Dr. Wakelin didn't stay there very long after I arrived. It was less than a year, wasn't it? He departed sometime after President Kennedy was killed. Possibly, he didn't actually leave until just before Dr. Morse took over. But as soon as Johnson became President of the United States, he was determined to get his own appointee into the office.

When I arrived at the Pentagon in 1963, Fred Korth was Secretary of the Navy. Kennedy initially made John Connally his SECNAV but Connally resigned after 12 months to run for Governor of Texas. Kennedy nominated Paul Nitze for the job, but Nitze's confirmation was held up for a long time in the Senate on the grounds that Nitze was a peacenik or something like that. Korth stayed until 1 November 1963 and then, Undersecretary Paul Faye fled up. Kennedy was assassinated on November 22. Once Johnson became President, things happened in the Navy Department that I remember well. The name of Kennedy's nominee for Secretary of the Navy, Paul Nitze, had been sitting in committee for a long time. President Johnson quickly cleared that up and Nitze came over as Secretary of the Navy from being Assistant Secretary of State for Disarmament or something like that. I'm trying to recall, because I remember clearly Captain Moran flying up to the Cape in New England to pick Wakelin up, bring him back and tell him the news that he was fired. Those are my words, but that was what happened. I thought it happened very soon after Johnson took over, but I don't remember. When it did happen, Morse was the guy who relieved Wakelin. I do remember taking a copy of the RDT&E management guide and giving it to Dr. Morse so that he'd know what he was stepping into.

INTERVIEWER: According to the Office of the Secretary of the Navy, that was the 1st of July,

1964.

ADMIRAL SNYDER: That could easily be correct. I don't remember how long after Kennedy died that the change took place. R&D was strictly on a technical basis. I do know there was a discussion in the White House about whether McNamara should remain the Secretary of Defense, because that was far more important than the Secretary of the Navy. Johnson also cleared the roadblock so that Nitze could become Secretary of the Navy, and Nitze stayed in that office for a long time. Kennedy had nominated Nitze to replace the nominee who died. Wasn't there a man who died before he could come to Washington to take the job? Undersecretary Red Faye was a politician and his nomination was a political payback. Faye was, in fact, one of the President's cronies. He played poker with the President of the United States, and that was a pretty powerful position. People in the outside world might not understand that, but in this town, that was a pretty powerful thing. He was out there, with no aides and nobody to keep track of what he was saying, and he was with the President of the United States and four or five buddies playing poker.

Let me go back a step. Connally was the guy who was riding in the car with Kennedy when Kennedy got shot. I remember one other thing. I remember Secretary Korth defending Assistant Secretary Wakelin at a hearing. Korth as Secretary of the Navy and Wakelin, his assistant secretary for R&D, were having a discussion in either the House or the Senate over the issue of the TFX airplane, which was the airplane for all three services. Secretary Korth got up, interrupted Wakelin's testimony, and said, "Jim, leave this room!" He turned to the chairman and said, "Don't call my people eggheads. These people are dedicated. They are trying to find out what the answers are."

I'm a young novice. In a Senate hearing, you were going to tell him to get his butt out of there? I didn't know Korth. That was the first time I had ever even to the Capitol. I remember we talked about him when John Craven, who was later the head of the Deep Submergence Systems Project and had been involved with the DSSRG, brought the report to me to show to Dr. Wakelin. I said, "Oh, well, we have to show this also to the Secretary of the Navy and, I hope, to the President of the United States." I shouldn't have been telling John anything, but by that time, I realized that nobody read these reports. I can remember telling John, "You've got to give me three pages for the Secretary of the Navy and a one-page only condensation of that so that I can underline three words in case I get it to the President of the United States." I can see John now, coming down the E Ring with his grocery cart and a stack two or three feet high and this little thing on the top for Dr. Wakelin, who is tickled to death, but he reads a little more than the Secretary. Nitze only read the short version. I can remember that clearly. During that time frame, before Kennedy was assassinated, we were doing an awful lot. In fact, we had finished our movie, *Science for Survival*. We were looking for gimmick titles. I remember I even kept a copy of that movie. It featured the Interagency Committee on Oceanography and we had pictures to show that the Navy wasn't running the world. It was very subtle. In fact, you probably remember that ocean research in those days was actually done by the Assistant Secretary for Research and Development through the Office of Naval Research and was later taken over by the Oceanographer. *Science for Survival* was the gimmick title for that first movie on the interagency business and the oceans. It showed diving and some other things. President Kennedy had agreed to, and did, introduce the movie. He also closed the film. He opened it and closed it. I was over at the White House in President Kennedy's movie room reviewing it with one of his

staff when the word came that he had been assassinated. President Kennedy was pretty pro-oceanography, including diving, and he was an ex-naval officer. I think our ocean programs would have gone a lot faster in the Navy if he had survived. It took us a long time to get President Johnson interested. We did get him interested, though. We got him to speak at an ESSA, or the Environmental Science Services Administration, as it was first called, ship commissioning. I can remember being criticized for writing words for the president's speech. I said, "Well, the President certainly doesn't write his own words for a speech about an oceanographic vessel. But those are side issues. It shows, though, that in that time frame, the Navy was not interested in taking charge. The Navy was interested in getting other agencies to help us understand more about the ocean so that we could get better weapon systems. We had figured out, for example, that if we could make a torpedo three times as effective, the cost savings would be unbelievable. In fact, destroyers could not carry enough torpedoes, so it became even more of a necessity to understand the ocean. Diving was part of our appeal and the Supervisor of Salvage had used diving for years as a doable function. I think the Man in the Sea program and SeaLab were things we were looking forward to for the future, or what we could do later. I didn't realize how dumb it was, since the electronics we had in the SeaLab program were not solid state but filament, the old vacuum tube. That helium gas wiped out the vacuum tubes and we lost communication. Stupid little things like that used to happen. I think that was because we were using people to run the program who shouldn't have been doing that, but we couldn't do it any other way. We couldn't get anybody outside of the Office of Naval Research because they were the only technical people that the assistant secretary actually controlled and owned. He didn't own the Bureau of Ships. Some of the people in BUORD could have helped a lot. They

did help some, but if you had put them in charge of the program, it would have never gotten done. We made a lot of mistakes because we had a lot of people, including yours truly, who didn't really understand anything.

INTERVIEWER: But what you're talking about is a given in engineering progress. You make a technical advance and then have to have a whole generation of engineers trained to use that advance, instead of basing their experience on vacuum tubes and nitrogen under pressure and so forth.

ADMIRAL SNYDER: That is absolutely correct. You remember I didn't know biology and certainly had no knowledge about medicine and still don't. Yet, in my opinion, I made the decision to keep the Bureau of Medicine strategically involved with it and made the decision to convince the secretary to enhance what was going on in Bethesda in the diving program. I didn't know if Bond was a politician. I really could have cared less. I knew that he was a good spokesman. I knew he could get the attention of the assistant secretary. I knew the assistant secretary would listen to him. I knew that the assistant secretary wanted to do something but wanted somebody to tell him what to do, and I wasn't going to tell him because I didn't know. One of the things that kept me alive for five years was that if I didn't know something, I called somebody who did. I would say, "I'm sorry, sir. I don't know. I'll find out and let you know." That was so unusual in the E Ring, or it was in the 1960s.

INTERVIEWER: What happened, politically, was Captain Bond and his ideas, his proposals, were being held at arms length by the surgeon general's BUMED staff. Then, when Dr. Wakelin asked for a briefing, Captain Bond was sent because he was the one who had the background in

the subject. He was, in effect, bypassing the BUMED staff that was trying to discourage him.

ADMIRAL SNYDER: That was characteristic of both the Wakelin and Ed Snyder approach to life. It didn't matter what the chain of command was. Go find the guy who knew the most about it. I should mention one other thing. We only had five people on our staff then. When I came back from Vietnam, there were 165. There were only five people before. I could get in to see the boss whenever I wanted. He was always receptive. When you have 165 people, you have a constipated bureaucracy. We didn't have a bureaucracy. We were all tearing our hair out. I had to have outside people help me. I didn't have a staff. I had a secretary, a wonderful secretary, but all she could do was answer the telephone and keep me guided.

INTERVIEWER: Tell me more about the DSSRG.

ADMIRAL SNYDER: The Deep Submergence Systems Review Group was Admiral Stephan's last job. He was chosen for the assignment, and he retired when it completed its work. When I came aboard, the oceanographer was a meteorologist or somebody. I can't remember. It was not Admiral Stephan. I know that because it was during Dr. Morse's time frame. When we lost the A-bomb, I got hold of Ocean Systems in New York to help us out. Admiral Stephan was the president of Ocean Systems, which was 60% owned by Union Carbide, 30% by General Precision, Ed Link's company, and 10% by Link, personally. I know Union Carbide was involved because I knew the guy there. That brings up another issue, the preparation of the pamphlet "Effective Use of the Sea,"<sup>4</sup> a product of the Panel on Oceanography of the President's Science Advisory Committee. The chairman of the panel was Dr. Gordon J. F. MacDonald of the University of California in Los Angeles, who later became head of the Environmental Protection Agency under Nixon. The vice chairman was Herb York, who by then was at the University of

California in San Diego. The pamphlet was written during the time frame when the Weather Bureau was trying to become leader of civilian oceanography. That was supported by Wakelin, in a sense, and was certainly supported by him for years afterward. President Johnson signed "Effective Use of the Sea." It documented the Navy's first step forward to volunteer as the ocean engineer for the U.S. Seen by some people as a power grab by the Navy, the Navy looked at it reluctantly as something that Snyder must have been doing.

Dr. Frosch then replaced Dr. Morse. I left the office in 1967 as special assistant to Dr. Frosch. When I returned in 1971 as the oceanographer, Dr. Frosch was still there. He served until January 1973. He was there quite some time while I was the oceanographer. In fact, he was the one who wanted me to be the oceanographer. I'm rambling, but while I think of it, I can remember clearly what happened that day. I was a fresh caught admiral, or relatively fresh. Admiral Zumwalt was the CNO. I had been told to leave my job as the COMTRALANT, or Commander Training Force Atlantic Fleet, in Norfolk at least two days a week and take over as additional duty the job of running the Office of the Oceanographer. Admiral Behrens, who was then the oceanographer, had been sent by Admiral Zumwalt to work over at NOAA, where he established the billet of Naval Deputy to the Administrator of NOAA. I was standing in the hallway, having a friendly conversation with Dr. Frosch in the corridor outside his office when Admiral Zumwalt came down the hall and started to talk to him. Dr. Frosch called Zumwalt 'bud.' He said, "Bud, I want Ed to be the Oceanographer of the Navy." But Zumwalt responded, "I want him to at least try to be the Atomic Energy Commission (AEC) Director of Military Applications." The reason he sent Behrens to NOAA was his great interest in getting the Navy

involved with other federal agencies. The Director of Military Applications had never been a Navy job. He was the one who ran the weapons side of the Atomic Energy Commission, a very powerful position. Up until that time, this director was, by law, the only weapons tie between the Department of Defense and the Atomic Energy Commission, in order to be sure that the military couldn't make their own weapons. It has been changed since then. I was well aware of that. I think somebody had told Zumwalt that I was a flag officer who had served at Los Alamos and Livermore, and that might be the Navy's only chance to get the job. Frosch and Zumwalt were discussing this back and forth and at that same time, one of the cute gals from the undersecretary's office walked by. I stopped listening to both the CNO and the secretary and turned my back and say something to her. Dr. Frosch, and I can see him now, turned and looked at Zumwalt, smiled and said, "Now, you know why I want Ed Snyder. Is there anybody else who can do bottom contour mapping better than Ed?" Everybody started laughing. Zumwalt said, "Okay, but I get first shot at him with DMA. If he fails, then you've got him." I did fail, but that's a two-hour story. Jim Schlesinger was Chairman of the AEC then. Normally, there would be one individual from the Air Force, one from the Army and one from the Navy interviewed. Fifteen minutes were allowed for each. But I was first on the list and my interview with him lasted an hour and a half, and the other two were mad. There was a book about Japan, *Shogun*, which had recently come out. I had been given a copy by the vice president of one of the oil companies and had read it. You know me. I hardly ever read anything other than technical publications. But I was fascinated with that book. You know how these old men on the staff sit there and read through their aides. One of them could hardly see but turned toward me and asked, "Admiral, have you ever read the book *Shogun*?" I said, "Yes, sir." He was reading his

questions and asked, "What did you think of it?" I replied that it was the best book on leadership I had ever read. That woke Schlesinger up, because he must have read it, too. My reason was that it said you cut your head off with a sword and give it to your boss on a platter, if he asks for it. That's pretty good leadership if you can get away with that, in my opinion. Schlesinger picked up on that and we got in a tête-a-tête. At one point I said, summarizing, "Sir, if the CNO told me to shovel horse manure in Manhattan, then I would be the best shoveler of manure there was in New York City!" I think that was my reply to him saying, "You don't seem to really want this job, but I'd like to have you," or something like that. At that time, I knew probably more about how the system worked than most people. I had been at both Livermore and Los Alamos. I had actually been a field manager and AEC's representative there. When people asked, I would tell him them what was wrong with both Los Alamos and Livermore, and there was plenty wrong with them.

INTERVIEWER: But the appointment went to somebody else?

ADMIRAL SNYDER: It went to the Air Force, probably. I think Schlesinger felt that I didn't want the job. That's my guess. He had to be interested. You don't go beyond 15 minutes when you've got a tight schedule for the whole day and take that much time. We had a real, person to person conversation about what was wrong with Los Alamos, what we could do better and so forth. He was interested. Whether that had anything to do with his choice for the appointment, I really don't know. But I really didn't want the job. The predecessor had fixed it up so that when he retired, he could keep the responsibilities of the job as a civilian. The new guy coming in wouldn't do anything. That was no job at all. It had been a very tricky one, anyhow. In those days, you were dealing with the group that decided who got what weapon. That was after the

time when the Air Force had set up Dr. Teller at Livermore, thinking they could get their own atomic energy laboratory. Of course, the law and Congress and everybody else stepped in and said, "No. That belongs to the Atomic Energy Commission, period!" We had two competing laboratories, as opposed to the original concept. The Air Force denied it, but they wanted their own bomb makers. That's another subject that has nothing to do with oceanography but it is an interesting subject. The Air Force wanted to say that you could not build a military weapon system smaller than 54 inches in diameter. One reason for that, without being written down, was so we couldn't fly them off an aircraft carrier. Teller invented a 39-inch one with twice the yield, and that put the Navy back into the carrier business at Los Alamos. Those were the things that used to happen in the Washington arena. The outside world didn't realize that and few people really knew what the heck was going on. You had decisions being made sometimes without any technical knowledge to back them up. I may be exaggerating, but I think it certainly was true in the 1960s. Can you imagine another weapons system like Polaris, which was built under President Eisenhower? There was no way at all. I mean, the President had a meeting with Admiral Raborn, Dr. Teller and a couple of other people. They convinced him it was important. The President said to do it. It started immediately and was completed in three or four years. It was done on an unlimited budget and finished on time.

INTERVIEWER: Did they stay within their projection?

ADMIRAL SNYDER: No. The weapon was lower in yield and shorter in range because the people sitting at that meeting with the President each had a different version of what the word 'warhead' meant. To Teller, 'warhead' meant the plutonium, polonium, and uranium. To a weapons designer, it meant that plus the fusing and firing circuit. But to the military people it

also included the re-entry body. I can't remember the exact figures, but Dr. Teller said, "I will guarantee you one megaton within such and such a weight." In the end, we attained that weight, but it also included the re-entry vehicle and the fusing and firing, so that cut the range down.

There was no definition of the term 'warhead.' When I went out to Los Alamos, it blew my mind that nobody was speaking the same language. You had the most brilliant man in the nuclear warhead business sitting with the President of the United States, and you had an admiral who was an aviator, not a physicist, and you had other people who were worried about Sandia Corporation, which hadn't been working on ballistic weapons. They had been working on fly-them-away weapons. There was a big difference and it caused a lot of problems, which we did solve, but that is a totally separate subject. That was three years of malarkey.

INTERVIEWER: Go back to the Stephan Committee.

ADMIRAL SNYDER: I think the Stephan Committee gave the Navy its ability to focus together all of its recommendations. Certainly, it got the Navy moving, but it would not have moved if it were not for Wakelin. He took that report and started to implement it. When Wakelin left, Dr. Morse came aboard. Dr. Morse implemented the engineering side even more than Wakelin because Morse really believed in it. When Frosch came aboard, you had not only a scientist but also an individual who had a tremendous background in underwater acoustics and had come from DARPA. He possessed knowledge that neither Morse nor Wakelin had. Both of them had to learn on the job. Wakelin had to learn how to make the office function. Morse had to learn how to deal with the bureaucracy. Frosch came from DARPA, which I have to call the bureaucracy. That was advanced research at DOD and he really knew what he was talking about. You saw things happening.

INTERVIEWER: Was the Office of the Oceanographer set up as a result of the Stephan Committee report?

ADMIRAL SNYDER: The simple answer to that is yes, but not directly. The Office of the Oceanographer was set up because yours truly realized that it was impossible to tie those things together as everybody wanted them unless you had somebody to tie them together. Although Admiral Stephan, if he is still alive, will tell you that he was the first Oceanographer of the Navy. He was not. He was the Hydrographer of the Navy. Wakelin was the first Oceanographer of the Navy.<sup>5</sup> The next guy who was hired I didn't care for at all. When Dr. Morse came aboard, we had a discussion about needing to get rid of a bureaucracy that talks about meteorology and oceanography and diving, and really start bringing it together. Dr. Morse was given permission by the Vice Chief of Naval Operations to go pick his own oceanographer. We went on field trips and that was when we picked (RADM Odale) Muddy Waters. I was accused of picking Waters because his name matched that of the Chairman of the House Committee, Mendel Rivers. It was Chairman Rivers and Admiral Waters. I was with the boss when he made that decision. I don't know why he chose him. But he did choose him and make him the first oceanographer. Maybe the one before him was the first legal oceanographer. It's not clear because we didn't even have a designated oceanographic program until Secretary Nitze signed the instruction that established the Oceanographer of the Navy, the Assistant Oceanographer for Ocean Science, the Assistant Oceanographer for Ocean Engineering and Development and the Assistant Oceanographer for Operations. I can't remember whether that was signed during the tenure of Morse or Frosch. But it was signed before I left because I remember taking it up to the Secretary's office. When Secretary Nitze attended my going away party, he asked me, and I'm sure it was just out of

courtesy, "What did you accomplish in these five years?" I said nothing, and he said, "You must have done something." I said, "Yes, sir. I got you to sign two pieces of paper." He asked, "What were they?" I said, "Creating the Oceanographer of the Navy and Op 95." He said, "That can't be true." I said, "Well, let's put it this way, Mr. Secretary. All the mistakes I made would fill the largest hard drive you have in the computer and I couldn't even get my accomplishments on a little disk." Op 95 was the creation of a czar for anti-submarine warfare (ASW). Congress pushed that on us. I can't remember which congressman pushed it on us but we were not doing well in anti-submarine warfare. There were big arguments that submarines could sink carriers and so on.

There were only five special assistants in the office at that time. There was one called 'surface,' another called 'air,' one for laboratories and another one called 'technical assistant.' I think there was one more, but I can't remember the title. At that time, I was surface. Dr. Morse made me submarines, also, because when Milt Shaw, who was the technical assistant and had come from Admiral Rickover's office, left to set up something in the Atomic Energy Commission, Admiral Rickover could not provide a uniformed qualified nuclear submarine officer as a replacement. Dr. Morse insisted that research and development had to include nuclear because diesels were dead, as far as the future was concerned. They were not dead in submersibles were concerned, but dead as far as the active submarine force was. That was when Morse assigned me as the Special Assistant for Submarines, and another officer who came aboard as the Special Assistant for Surface relieved me. When the executive assistant got sick and was in the hospital, Morse assigned me as his aide and executive assistant because he didn't like the guy who was in the hospital. That had nothing to do with oceanography. It just had to do

with Dr. Morse. When he left that office, he wanted to be president of a major university. The aide who controlled his schedule was always letting in the presidents of Grumman, Northrup, Lockheed and so forth, and that got Dr. Morse really uptight. When Dr. Morse did leave the Pentagon, it was to become the President of Case Western Reserve University in Cleveland. He was to put together the Case Institute of Technology and Western Reserve. About a year after he left, he called me on the phone and said he wanted me to retire, come up there and help him out. I said I didn't know anything about running a university. He replied, "Well I thought I did, but that's not what I am doing. My job here is to keep the 'Marine Corps' and the 'Army' together," meaning 'Western' and 'Case.' It was also to raise money, and he said, "You're pretty good at knocking heads. You come here and help me knock them." Then, he got fired. He won't tell you this, but he got fired over some issue in Cleveland. He was trying to be racially sensitive. Whoever ran the university didn't like what he was doing, I guess. It had nothing to do with education.

Paul Gaffney was my extraordinarily talented flag lieutenant in 1973, when I was Oceanographer. He had a brilliant Navy career and after serving as the Chief of Naval Research, was promoted to vice admiral and appointed as the President of the National Defense University at Fort McNair. Paul recently retired and has become the President of Monmouth University in New Jersey.

INTERVIEWER: During the period you were in the secretary's office, Lew Melson was in the Office of Naval Research (ONR). He came in about 1963 or 1964. He said that there was a proposal to set up an oceanographic office and it involved Admiral Leydon. What did they propose?

ADMIRAL SNYDER: Admiral Leydon was Chief of Naval Research. I was trying to write the oceanographer's charter. It started under Dr. Wakelin, who gave the order to emphasize oceanography in the Navy. One of my jobs was to sit down and, in effect, write a charter for the Oceanographer of the Navy. You can well imagine that was not exactly the easiest thing in the world to do. You were cutting into the knickers of people other than the Chief of Naval Research. Under procedure current at that time, and even later, when I was the oceanographer, the Assistant Secretary for Research and Development ran the Office of Naval Research. The Chief of Naval Research did not report to the CNO. He reported to the Secretary of the Navy. But the secretary had delegated that responsibility to his Assistant Secretary for Research and Development during the time I was there. The Office of Naval Research ran the secretary's budget since the ONR comptroller was the comptroller for ASN(R&D). I had written in the RDT&E Management Guide that ASN(R&D) was the sponsor for research funds appropriated by Congress. I didn't know any better that he really wasn't, but this statement gave him a lot of clout. That meant a lot of other things were involved with it, too. The other issue was naval development, and not just basic research but development, and that brought in the materiel establishments. They did not turn out to be a problem because it was going to be a loose confederation. Nobody was going to own anything, but they all had to report. The concept I had, which the secretary bought, was to have an Assistant Oceanographer for Research, Assistant Oceanographer for Development and Assistant Oceanographer for Operations. Well, the Oceanographer for Development would be on the materiel side and in those days, the Secretary of the Navy ran the materiel offices, not the CNO. That changed later. The only problem I had was with operations, because operations came under the CNO. It was probably a technical

mistake, but I chose the submarine community to be the Assistant Oceanographer of the Navy for Operations. That was in my mind, but it took two or three years to get it signed. In fact, I remember when Secretary Nitze came to my going away party. He was the Secretary of the Navy before he was made Deputy Secretary of Defense. He said, "Snyder, what have you accomplished?" I replied facetiously, as I always do, "Not a thing, Mr. Secretary." I didn't even know what I could say. I could fill an entire hard drive on a computer with all my mistakes. He looked at me and said, "Now, come off it." I said, "Well, I got you to sign two pieces of paper, Mr. Secretary." He laughed and asked me which they were, and I said, 'the charter for the Oceanographer of the Navy and the establishment of Op 95, or the Anti-Submarine Warfare Office. Everybody in the room laughed, of course, but it was a real accomplishment in those days to get a change.

That change was shoved down the throat of the submarine community. I would have had no problems had Admiral Eugene Wilkinson still been there, but he had been transferred to Japan. The Deputy Submariner was Buck Dietzen, a classmate of mine at the Naval Academy. He absolutely didn't want to work with anything except submarines. It did finally happen, but not until the end of Dr. Morse's term. It took years to get it approved. I think that the Chief of Naval Research was also somewhat to blame because ONR had the problem of 'Not Invented Here,' the National Institutes of Health approach. Strictly speaking, in the Navy ladder for research and development, ONR was supposed to do basic research and then pass the results on to one of the bureaus. But ONR did not want to pass anything on if it was good. They wanted to keep it and continue to work on it themselves. The Bureaus, in turn, didn't want to take anything from ONR because they wanted to be the guys who invented it. I'm exaggerating, but those are the kinds of

things that made it very difficult to get an agreement. In the materiel side of the house and at the Office of Naval Research, everybody either agreed or we forced it down their throats. I honestly don't know the difference, but from where I sat, they all seemed to cooperate. They would come over to my office and we'd sit down. I'd say, "Here's what I need to do. Let's work it out." They would be glad to work it out. That happened particularly well with the Man in the Sea program because, and you've got to realize that it was a mistake, we were having the ONR research people run the Man in the Sea program. The Supervisor of Salvage should have run it, in my opinion. I don't know whether you agree, but I'm talking about the operational side. Let the R&D start with ONR, but let them work together with the rest of the Navy. You didn't have anybody who was really pushing that part of the program. The Supervisor of Salvage was pushing diving, hard hat diving, but I don't think his office understood that if you really wanted to explore the ocean and exploit it, you needed man to be able to do the work, on occasion. Of course, that really showed up when the intelligence community started getting involved. I don't know what is classified now, but obviously, we occasionally sent submarines down in certain parts of the world with divers who then worked outside the submarine. I think that was published in the book *Blind Man's Bluff*.

At the time, Wakelin had given me two jobs that I didn't like. One of them was to answer all the kook letters sent to the president's office or to Congress. I remember one of them, in which we had to put a line item into the budget for the flying submersible aircraft carrier. Now, you figure that one out, a flying submersible aircraft carrier! I think we put fifty grand into that scheme, and it took me two years to get it terminated. Then, when I came back from Vietnam, it was back in the budget again. That was one of the jobs I didn't like. The other job was dealing

with the SI, or special intelligence, world. At that time, the R&D Assistant Secretary ran the SI programs. That changed while I was the oceanographer. When Dr. Potter moved from ASN to undersecretary, he took all of those programs with him. Potter ran them during the days of the submarine projects.

I'm getting off the subject, but how did you get somebody interested in Man in the Sea? We needed that as an alternative or backup. We didn't need to say that everything we were going to do is going to be manned. I think that became a big problem with NASA. They said, "We can't do it if it isn't manned." Well, as you know better than I do, we used to talk about how much more expensive it is to put man in the loop, physically. There are times, though, when I think it's absolutely essential. Other times, it's a lot cheaper, and just as efficient and cost effective, to do it with a remote sensor. I'm talking about in the ocean. I'm not that conversant with space. I think you would have recommended to me that I use a submersible-type of remote link of some sort before I put a man down there if we hadn't done it before, just to understand where we were going. In general, I think the Supervisor of Salvage was interested only in salvage.

INTERVIEWER: Well, it's interesting that Lew Melson was also an engineering duty officer and a colleague and friend of Bill Searle's, who is, I think, the Supervisor of Salvage you're talking about

ADMIRAL SNYDER: No, I'm talking about his predecessor. I don't remember his name. I never had a problem with Bill Searle.

INTERVIEWER: When Bill Searle came in, and he arrived about that same time, in 1964, Lew Melson wanted ONR to develop better tools and equipment for divers. It was an ONR program that Lew Melson tried to prosecute through the SeaLab experiments. He had many difficulties

that he will gladly tell you about. There were lots of people in the Navy department who were interested in advancing Man in the Sea.

ADMIRAL SNYDER: Yes, but I think Captain Melson was the only one who was actually trying to take charge and get something done at ONR, and only ONR was doing it. I kept telling them how important it was, in a classified sense, to have the capability of putting a man outside a submarine. It was obvious to me. I used to kid the boss. I would walk in his office and say, "Well, the forces of darkness got to me again today." He'd ask what I meant. I'd say that the submarine community had closed their doors again. I'd say, "I may need your help," and he'd say, "Okay, call me if you need me," or something like that. It became a joke in the office. But that was the time when Admiral Rickover was absolutely and totally in charge of nuclear submarines. He didn't really appear to dislike research and development, but he didn't like it. Then, he almost went down on his hands and knees to get my boss to agree to let him have the first nuclear research submersible, the *NR-1*. We had an interchange with R&D for not the first time. After that fiasco with the USS *Seawolf's* sodium reactor, Admiral Rickover just didn't trust anybody in ONR.

The assistant secretary talked the Secretary of the Navy into hosting a lunch with Captain Cousteau for the Man in the Sea program. Wakelin had been the director of National Geographic's research team, committee, or whatever they called it. He had been involved with the *Calypso* and with Captain Cousteau on other subjects. We were using Captain Cousteau on other things but needed somebody to get the secretariat up to speed on how important it might be to have manned capability. We weren't telling Captain Cousteau about the long-range view of using it in the classified sense, only about the ability to exploit the ocean. I think it worked. I

remember it only because Mrs. Cousteau was the first woman ever to have eaten in the Secretary of the Navy's mess.

INTERVIEWER: That dinner took place after you arrived because you were present at the dinner. I also think it was before George Bond briefed Dr. Wakelin about his SeaLab proposal. Is that right?

ADMIRAL SNYDER: Oh, yes. As a result of the DSSRG, that review group we were talking about, Dr. Wakelin wanted to support the Man in the Sea program. That was what we called it, 'Man in the Sea,' but we didn't have it all clear in our minds. We made a heck of a lot of mistakes. I remember the first absolutely stupid mistake was that we forgot that vacuum tubes were not solid state in those days. Helium wiped out a vacuum tube. There we were, trying to do research with cameras and stuff, using vacuum tubes in a helium atmosphere and all of a sudden, the gas wiped out the entire communication net. Those were the kinds of things with which ONR should have helped us. There was no reason in the world, in my mind, that the Assistant Secretary for Research and Development should have been running a technical program. Wakelin did not want to run a program. He just wanted to see that it got going and that he was kept aware of it.

INTERVIEWER: It was initially assigned to ONR?

ADMIRAL SNYDER: Absolutely it was, because Wakelin owned ONR. He owned it lock, stock and barrel. He had the authority to promote civilians and was always listening on the Navy uniform circuit for who could be the next Chief of Naval Research. Admiral Leydon, for example, never went before a selection board. Under the law, the Secretary of the Navy could appoint a commander or above, regular or Reserve, active duty or not, to be the Chief of Naval

Research, and that officer while so serving would be a rear admiral upper half. That was, to my knowledge, the only law we had in the Navy that permitted that.

INTERVIEWER: Could ONR command Navy units at sea?

ADMIRAL SNYDER: No. It absolutely could not. You said 'Navy units,' and Navy units by definition are commissioned units.

INTERVIEWER: Well, how about the SeaLab?

ADMIRAL SNYDER: That was not a Navy unit. That was a research unit, a research operation. In fact, that issue came up the day Admiral Moorer was sworn in as Chief of Naval Operations. The Chief of Naval Research had a merchant vessel up somewhere off of the Pacific coast for an experiment. They were going to blow it up and sink it. Well, it didn't sink, and all of a sudden, yours truly was told to get involved with the thing and find out what was going on. To make a long story short, the vice chief, who was Admiral Rivero, I think, gave me a lecture like never again. He said, "Snyder, never again do you ever let anybody in the Office of Naval Research command anything that is at sea."

INTERVIEWER: That was the ship *USS LeBaron Russell Briggs*?

ADMIRAL SNYDER: I can't remember. It was not manned, of course. It was full of explosives. Then, Admiral Moorer got involved with it. From then on, somebody woke up to the difference I just asked you about. Is it a naval vessel? For example, is an oceanographic vessel a naval vessel in today's Navy? It was then, but is it today? Technically, it is not, because it may not be a commissioned ship. It's USNS. But in reality, they are ships and under the command of the CNO. I found that out as an admiral, when the Turks crossed over Crete. They were going somewhere to attack somebody and saluted my oceanographic vessel sitting in port. The CNO

blew his stack. Every morning from then on I had to attend, or send a representative to attend, the CNO's morning operational briefing.

INTERVIEWER: That was while you were the oceanographer?

ADMIRAL SNYDER: Yes, but going back to what you were talking about, there was a lot of interest in research, but nobody was willing to put his money up. In that sense, you were forced to use ARPA, the Advanced Research Project Agency, which was basic research for DOD. In my opinion, it was not that good. But I have to be careful about that because Dr. Frosch was the director of ARPA before he became the Navy's assistant secretary. He certainly was a good assistant secretary.

Captain Lew Melson was a remarkable person in a lot of ways. I think he made a major contribution but never got credit for it. He never made a show of what he was doing. Melson was very quiet, very confident and very capable. I like guys like that. If he told you something, you could trust it. I didn't have to do further research. I could go in and tell the boss, "This is what it ought to be." You knew George Bond far better than I did. I think if Bond wanted to have access to the assistant secretary through me, he would have polished me up to attain it.

INTERVIEWER: As a result of the *Thresher* loss, did the SeaLab program get attention from the Office of the Secretary of the Navy? Did it get approved for execution and assigned to ONR for that purpose? Also, was the Deep Submergence Systems Project (DSSP), PM-11, set up as a consequence of the report DSSRG's report when it came out?

ADMIRAL SNYDER: That's correct. ONR had done SeaLabs I and II, but SeaLab III was transferred to John Craven at the DSSP to carry out. John Craven was, to my knowledge, the first civilian, or civil servant, chosen to run a major project within the Navy materiel establishment.

It was intended as a permanent selection but interestingly enough, within a month after I left ASN, all of a sudden there was a Navy captain running the DSSP.

INTERVIEWER: Why was there the change? It makes sense if Craven was just an interim tenant doing the job until they found the appropriate ED. Dr. Craven had a full-time job as the chief scientist of PM-1, the Polaris Project Office.

ADMIRAL SNYDER: No. They relieved him of that job when he became the program manager at the DSSP. He thought he was still their chief scientist. He may have been to Admiral Raborn and Admiral Levering Smith, but his official job was the PM-11 program manager and that was to be permanent. I don't care what anybody else says. That was permanent. The Assistant Secretary for Navy R&D did it. You've got to remember the Secretary of the Navy owned and controlled not just ONR, but the entire materiel setup. We established the Chief of Naval Material as a four star billet. The blue suit Navy didn't do that. They didn't want a four-star running something big outside their chain of control, pushing buttons and stuff like that. You know that. ASN controlled NAVMAT and PM-11 came under NAVMAT. We made a recommendation for the first Chief of Naval Material. Remember that it was four stars, and in those days, we didn't have many of them. It was not like the world today. You haven't got a room big enough to bring them all together. I'm being facetious, but it was important and meant that the Navy had to give up another four-star billet somewhere else in order to make the Chief of Naval Material four stars. We made a verbal requirement, not in writing but verbal, that no one would be promoted to that job unless he had previously demonstrated successful management of a major program. I forgot that it was another thing that I got Secretary Nitze to sign. Who did that leave you with in those days? Who was the most successful program manager in the 1960's?

It was Red Raborn, the head of the very successful Polaris development program.

INTERVIEWER: Was he the Chief of Naval Material?

ADMIRAL SNYDER: I thought he was, but maybe not. I thought he was the first one. Ike Kidd was the exception. Ike Kidd was in my first class at the Naval Academy, so I know him really well. He was not a technical man no matter what he tells you. He was a good, rough and ready sailor but became the Chief of Navy Material. I don't remember when that happened, but I was the oceanographer. I remember getting a telephone call from him. He was one of the two guys that called me 'Eddie.' I got this call and he said, "Eddie, are you on the squawk box?" I said, "No. Who's this?" He said, "You know who this is. This is Ike." I said, "Yes, sir," and he started chewing me out because he didn't have proper maps. He was then COMSIXFLT. I said, "Whatever you want, Admiral. I'll be sure to get it to you," and we hung up. But he knew me well enough to do that. I can remember clearly that when I was working for Wakelin, Kidd was the executive assistant to the CNO, Admiral Moorer. He and Zumwalt were specially selected early for rear admiral. Zumwalt got sent to Vietnam, where he could put his stars on. Admiral Moorer may disagree with me on this, but he kept Ike as his executive assistant until Admiral Moorer became Chairman of the Joint Chiefs of Staff (JCS), as I remember it. I can remember that I'd walk down the hall and there would come Captain Kidd. I was a commander or a captain and I'd back up against the bulkhead on the E Ring. He'd ask, "What are you doing that for, Eddie?" I said, "When you knife me, I want to see it coming." That was what I thought of Admiral Kidd. But he wasn't a technical man and in spite of how much I liked him, I was very upset that he was chosen to be the Chief of Navy Material when I came back. Then, I was out of the loop. The oceanographer was not in the loop of running things. I don't remember the exact

number of staff persons in the assistant secretary's office when I came back, but it was over a hundred. When I first went there, it was just five. That was a real difference. It was when bureaucracy took over. With five people, if I have to know something about medicine, I'd go outside the office to you, and you would help me write it. I might have changed the tone so that it would have fit the secretariat, but I didn't know what was going on in medicine. I didn't know what was going on in a lot of subjects. I'd have people come over and we'd sit down and they would help me. Admiral Wilkinson would let me walk into his room at any time because my title was changed from Executive Assistant to Special Assistant for Submarines. I was not wearing dolphins. I never wore dolphins. Admiral Wilkinson was Op 02 or Op 03 before he got fired and sent over to Japan. He was running submarines within the Op 03 system before the submarines had their own Op man. I think he was in Op 03, and the reason that I had contact with him was because of what we were talking about before, a submarine admiral was the Assistant Oceanographer for Ocean Operations.

INTERVIEWER: That was also true in the 1960s?

ADMIRAL SNYDER: It was true in the late 1960s, yes, just before I left. I left in December of 1967.

INTERVIEWER: Let's talk about the formation of the Office of the Oceanographer. The hydrographer's office was changed by the Secretary of the Navy. The title for the admiral in charge was changed from hydrographer to oceanographer?

ADMIRAL SNYDER: Well, we changed the title before we actually got the instruction. We just automatically said that the guy who relieves Admiral Stephan, the Hydrographer of the Navy, will be called the 'Oceanographer of the Navy.' Stephan was moved, or retired, and took over as

the head of the Deep Submergence Systems Review Group. Another admiral replaced him but the assistant secretary or his aide did not choose him. When it became time for him to leave, Dr. Morse was the assistant secretary, as he had relieved Wakelin. Morse said to me, "I want you to go down and talk to the vice chief and get a list of admirals that he and I can agree on to be the oceanographer. We were making the oceanographer a title before it was approved. We didn't get that piece of paper until later. But you've got to realize with Wakelin, it wasn't hydrography, nor was it meteorology. He had a concept of Navy oceanography. In fact, he did own the Naval Observatory. I had forgotten that. His whole concept was to bring all of it together, and it started back in the early 1960s. There would be a program called 'Navy oceanography,' which would include the environment of the ocean, above it, below it and on the bottom.

INTERVIEWER: Did the hydrographer's office report to the assistant secretary?

ADMIRAL SNYDER: No. It never did. The admiral himself was made to report when he was called the oceanographer. I call it a change. I call it a drastic change. I don't know to whom he reported before. It was just someplace in OPNAV. A lot of people reported to some place but did not know to where they reported and did not have godfathers. A lot of enlisted ratings were that way, too. To make a long story short, we picked an admiral called Waters. His last name was Waters, and it became a joke. Chairman Rivers was going to approve Admiral Waters, even though Congressman Rivers wasn't in the Senate, to be the Oceanographer of the Navy. Then, Admiral Waters took over as the Oceanographer of the Navy. He was the first one selected by the assistant secretary. Dr. Morse chose him. Admiral Waters told me later that he knew that he was being considered for some job when he saw me coming out with the assistant secretary. Because the ASN had no business at all talking to him in mine force, that was an operational

thing. Admiral Waters became the Oceanographer of the Navy when I was leaving for the USS *New Jersey*. He wanted me to come to be the Chief of Staff to the Oceanographer. By then, it was a legal title and they had been moved to a building on Route 1 in downtown Alexandria, before later moving to the Hoffman Building. The office was established. There was a staff and the oceanographer, in effect, reported to two people. He reported to the Assistant Secretary for Research and Development and to the Chief of Naval Operations for operational things because, remember, he had an Assistant Oceanographer for Operations. That was the first time you had somebody who spanned from basic research to what was going on in weapons systems at sea on the ships. Admiral Waters was the first one who really had that job. Admiral Stephan kept telling me he had had it, but Admiral Stephan didn't control operations. He did control oceanographic programs. Admiral Behrens relieved Admiral Waters, and I, in turn, relieved Admiral Behrens.

Admiral Zumwalt was the CNO and he wanted Navy people to work with the other federal agencies. Of course, by that time, we had set it up so that the Oceanographer of the Navy was the Naval Deputy to NOAA. It wasn't called NOAA then. It was called ESSA, the female of ESSO. That got resolved while I was in Vietnam. When I came back as the oceanographer, it was NOAA. This is an opinion. I don't even know if Barhens is still alive, but I think he saw this as an opportunity to get three stars. They moved him from being the oceanographer, with additional duty as naval deputy, to a full time assignment in NOAA as the naval deputy or some title. That gave him the ability to deal with a presidential appointee. That made him automatically eligible for three stars. He did get that promotion from Admiral Zumwalt. Dr. Frosch, who was then the Assistant Secretary for Research and Development, and for whom I had worked before I went to Vietnam, called me over and wanted me to be the oceanographer. It

wasn't until after Dr. Potter left that the office began to grow exponentially. But by the time I left active duty, the Office of the Assistant Secretary of the Navy for Research and Development still owned the Chief of Naval Research and the Office of Naval Research lock, stock and barrel.

Legally, it was the only thing he owned entirely.

INTERVIEWER: Both as the special assistant in SECNAV, and later as the oceanographer, you did a lot of work to bring separated programs of the Navy department together and make them work together in the Office of the Oceanographer.

ADMIRAL SNYDER: That was an attempt that was obviously a failure.

INTERVIEWER: There were lots of successes. You put the Oceanographic Center in Mississippi.

ADMIRAL SNYDER: Well, I'll leave it to you to judge successes. I just felt so frustrated all the time. I even got an advisory group set up that really had some really high level people on it, including the first Op 95 admiral. At that time, Mr. Middendorf was the Secretary of the Navy, and I don't know why he was interested in oceanography, but he truly was. He would take me with him on all kinds of trips and things. When he found out that the oceanographer was the Antarctic Projects Officer and ran the Navy's part of the Antarctic program, he said, "Snyder, I want to go down there." I explained that I would have to get the Director of the National Science Foundation to agree. When he told me that he was the Secretary of the Navy, I promised that I would take care of it. I went over and told the director, who said only, "Ed, do what you want to do, but try to keep Middendorf out of our hair, will you?" I said, "Sir, I intend to do that but I wanted to avoid having a bunch of Ph.Ds trying to tell Secretary Middendorf what he can and can't do." We flew him down to the Antarctic, and he enjoyed it. But suddenly, he thought that

he controlled it. Actually, the NSF controlled the technical part while the Navy only provided logistic support through the oceanographer. In fact, that's why there's a peninsula in Antarctica named for Snyder.

INTERVIEWER: Oh, there is? Where is it located?

ADMIRAL SNYDER: I don't know. I'd have to show it to you on the map that they gave me. It's in the bathroom there somewhere hidden under the sink. Then, the White House budget people decided they wanted the NSF to pay for the whole thing. The NSF became the sole owner of the Antarctic program, including the logistics. I retired when that happened, but the director used to have me come over and we'd have lunch together and talk about it. Lockheed and some other people could taste running the program because NSF wasn't about to really run the logistic part. It was very expensive. One of the things that OMB wanted to do was find out what it truly cost, but there was no way you could have found that out from the Navy. The reason was because we'd pull a P-3 here and take a crew there, and the oceanographer would send the plane down or a ship would go down. When the NSF had to do that, they had to pay for it, every dime. All of a sudden, they knew what it cost.

INTERVIEWER: The Air Force and the Army also supported the Antarctic logistic programs. When full responsibility was transferred to the NSF, and the Navy connection was severed, were their connections severed at the same time?

ADMIRAL SNYDER: Well, connections weren't severed, but the NSF was put in direct charge of it, which made all those things reimbursable, theoretically. Whether they were all truly repaid, I don't know. For instance, as the oceanographer, I dealt with a lot of reimbursable programs but sometimes never asked for payment. I remember looking for a gun in Lake Michigan at the

request of somebody, and it was legally a reimbursable program. I went to the divers and said, "This is over Christmas. This is purely voluntary. If you volunteer, I'll see that you get Navy per diem, but I want a hundred percent volunteers. I don't want anyone thinking the Old Man is telling you to do it." I got more volunteers than I needed. They went over there and they found it, I guess. I don't remember the details. I did not consider that the situation demanded reimbursement. On the other hand, when the Air Force lost its hydrogen bomb, I was working for the assistant secretary and that was a totally different story. Dr. Harold Brown was the Secretary of the Air Force then, and I can remember very clearly what he said when I handed him the bill. He said, "Snyder, can't you just call this your Navy training?" It was a pretty hefty sum. It wasn't just the contract work. I wrote in the charges for the *Mizar* and the *Trieste*, a pretty big bill in those days. It was a long time ago, but it was a pretty big expense to send the *Trieste* halfway around the world.

INTERVIEWER: That happened just before you went to the *New Jersey*?

ADMIRAL SNYDER: I don't remember. I didn't go to the *New Jersey* until December of 1967, and I think this was about two years before that. Was it in 1966? I don't remember the date but I do remember that Dr. Morse was still the assistant secretary, so it would have to be before Frosch came in. Dr. Morse was the Acting Secretary of the Navy, because Secretary Nitze was out of town on an official trip. I have a memorandum on the Assistant Secretary's white letterhead paper that reads, "Ed, take charge and find it," or something simple like that, "Signed, Bob Morse." I thought, "Oh, boy!" It was on a weekend and we were pulling in the whole Navy. We were even pulling the flagship of the Sixth Fleet over there for one purpose, communications. It wasn't just R&D. I think you would call it a really operational thing.

Basically, the Air Force was talking to me on the telephone. They had a one or two-star general assigned to the problem because it was their weapon and they did not want anybody to find out why it was lost. It was lost because some major from the general's staff suckered the pilot of the bomber to let him fly up for the refueling and didn't know what he was doing. In my opinion, he didn't know what he was doing. But that was when the explosion occurred. Nobody was killed. It was absolutely amazing. But it broke the back of the bomber and it just opened up and all the weapons just dropped out. I think there were four. One went into the water because only one deployed a parachute. The wind got its parachute and took it into the water. We were doing all that on the weekend, and I mean that we were really doing it. They even assigned me a place to sit in the CNO's ready room because we were really operational. It really wasn't research and development, but we were calling on R&D to use their cutting edge new technology equipment to find and retrieve the lost bomb.

INTERVIEWER: ONR was involved?

ADMIRAL SNYDER: Oh, yes. ONR sent the *Alvin*, and it was the *Alvin* that found it. The *Alvin* was owned by Woods Hole, which was owned by the Office of Naval Research, which was owned by the Assistant Secretary, who at that time was the Acting Secretary of the Navy. Anyhow, I put all of this junk that reported on what was happening on Secretary Nitze's desk. When he came back on Monday morning, he was floored. It had hit the newspapers. But it was an Air Force plane. I don't think the relationship of the Navy to the operation was clear to the secretary until he saw my report. Then, things really started to happen. The president got involved. It became the highest level thing because unbeknownst to me, certain presidents or directors in various European countries had given unofficial permission to the United States Air

Force to fly over their countries with a loaded hydrogen bomb. Well, they basically said, “If you don't find the bomb and straighten all this out, you've got to stop your flights.” Here is my good opinion, which has nothing to do with fact. I always call it the ‘Air Farce’ because if that had happened, you would have had only one major nuclear program, and that would have been Polaris. I don't know whether you're aware, but the Navy couldn't have cared less about Polaris. Again, that is my opinion, and many would deny it, but the Navy really never supported Polaris because it was eating them alive, financially. They did support it, but you know what I mean by that kind of support. The Air Force could only have seen the incident as a threat. Can you imagine not being able to fly over in those days, when you didn't have cruise missiles in the airplanes? You had to physically fly over the target and physically drop your bomb. It became a number one problem. The Vice President of the United States was put in charge of the oversight committee. I was going over there with whoever was representing DOD, who happened to be Navy, by the way. I think it was the undersecretary. It wasn't my boss. It may have been the undersecretary. I remember this clearly. I went over to the meetings in the White House. I stayed out of the day to day bolts and nuts, and the work done by our contractor, Admiral Stephan's Ocean Systems. But when I found out how deep the area was, for instance, I discovered our CURV, or Cable-controlled Underwater Recovery Vehicle, couldn't go that deep. I called the director of the Navy laboratory on the west coast and told him to modify its cable. I remember that he said, “Who's going to pay for this?” I said, “It's going to be your butt if you don't do it, so don't argue with me about reimbursement.”

That was a bureaucracy. We had the number one problem in the United States of America, and I was getting, “I'm not going to do it until you pay me?” Come off it. But that's the

way life is. You know me well enough to know that my tone was not exactly pleasant, nor was it official. I could not have necessarily backed it up, either. But we were going to do it, and we did. The Air Force was absolutely one hundred percent cooperative. I remember we also got involved somewhat with the land business, even though that was the Air Force's responsibility. They had to scrape acres of radiation-contaminated topsoil, and their general asked me if our SeaBees could help. He asked, "Can't we get them over there and start pulling this contaminated dirt together?" I said, "Yes, sir." I called the head of the SeaBees and the Commander, Naval Facilities Engineering Command, but they only had one used bulldozer. I called the general back and asked if he could buy six bulldozers and fly them over there. He bought brand new ones and flew them over for the SeaBees to operate. The Navy couldn't do that. We didn't have that kind of money. I had sailors from a heavy cruiser wading into the shallow water in swimsuits, walking to see if they could find it on the bottom. I had the Atomic Energy Commission totally disagreeing as to where it was. I talked to a Spanish fisherman, and you know a fisherman as well as I do, but when he told me where he thought it went into the water. I accepted his word. His location was sixty miles away from where the Atomic Energy Commission-Sandia had decided it was, but that was where we did find it.

INTERVIEWER: When did you say you were talking to the fisherman?

ADMIRAL SNYDER: The fisherman was on the telephone. The assistant secretary was, in fact, with the CNO, who was running the operation from the Pentagon. But because Morse had been the Acting Secretary of the Navy at the beginning, he had put me in charge. The CNO's office was perfectly willing to have a shared responsibility and assigned a two-star admiral to run the operational part of the program in the Pentagon. I can't remember his name. Everything was

taking place in Spain. We had ONR involved, plus contract teams, so how did you communicate? We put a heavy cruiser on the scene. Then, we said, "Well, gee whiz, can't we use some of their sailors to double check the shallow water?" Everybody was having a ball from that viewpoint. I remember it so clearly. While it was going on, Dr. Morse was called upon to testify before Congress, but he was in the hospital by then. The Chief of Navy Legislative Affairs came in and said, "Snyder, you do it." I said, "I can't do it, sir." He said, "You didn't hear me. Go do it." I went over there, representing the Navy department, and gave this testimony and slides as to how we had recovered this weapon. Congressman MCC, before the Appropriations Committee said, "Well, Commander, do you need more money for this kind of program? This is very important, isn't it?" I said, "Yes, sir. He said, "Do you need more money?" I said, "Yes, sir." He said, "Well, how about ten million dollars?" I said, "That's a start," or something like that. He threw it in the budget and the Senate approved it, and McNamara's staff went right through the ceiling because there was a Navy guy, putting money in the budget with a directed program. Of course, that was not the right thing to do, but I was pretty naive about that. I had been dealing in the technical sense all the time and nobody cared about. But all of a sudden, I was going before the Chairman of the House Appropriations Committee, Congressman MCC, a very brilliant, powerful and honest man. I had dealt with him before on technical matters, and that shook a few people up. But it was so important to find the bomb, and we did find it, as you know. It was so important that there were a lot of bureaucracies involved, but it got done. To this day, it would be hard to actually document how it got done because nobody would believe it. You and I worked together a long time. You know what I'm talking about. But it did get done. That was Man in the Sea, too, by the way, because we wanted to put a man down there when we thought

that it was in shallower water. It actually fell into shallow water, but the parachute stayed partially open so that the current pulled the bomb into a gully and made it three or four times deeper than it was when it first fell. That was when the *Alvin* saw it. The *Alvin* saw the parachute and followed it. Some of the few things I have ever saved were the slides that I made for my presentation, because they comprised a summary of my recollections as to how we did it, what the names were and so forth.

INTERVIEWER: I think the SeaLab divers may have been sent.

ADMIRAL SNYDER: We wanted divers because we started out thinking it was in shallow water. For the deeper search, the *Alvin* was the nearest thing available, on the east coast. It was at Woods Hole, next to Hyannis, and the Air Force said they could pick it up at Otis Air Force Base and fly it over, which they did. As I remember, they flew it over, because it got there in a hurry, comparatively speaking. The *Mizar* was sent over, too. It also belonged to the Office of Naval Research. The CURV vehicle was on call. At that time, the Navy was the leader in undersea technology. You didn't have all these civilian companies, and the early ones did work under Navy contracts. You had them involved somewhat. You had them involved in the shallow diving and in shallow recovery. But the lost bomb was very deep when it was finally found. I don't remember the exact depth. Also, you've got to realize our concern about charges that the Americans had irradiated Spain. The Soviets tried to exploit that. There were four H-bombs. The bombs came apart and irradiated Spanish fishing grounds and the waters around them. They irradiated the tomato patches. I remember recommending to Secretary Nitze that he tell the vice president and the secretary of state he would authorize the Navy to buy tomatoes from Palomares farmers and feed them to our crews. That would prove that they weren't contaminated. Of course,

we had already done the tests and knew they weren't contaminated. But the Russians would try to convince everyone that they were. They were watching us all the time. An AGI, or whatever you called the Soviet spy ships, was sitting there, pretending it was a fishing ship, but it was watching everything. That caused me to tell the secretary that if we didn't find the lost one, I had another one in my back pocket, fixed up to look exactly like the real thing, including dents. We could slip it in there and pull it up. He said, "That's a good idea, but keep it to yourself, because the Soviets are going to accuse you of just that when we do locate the real one."

I always looked at Man in the Sea as a function of the operational Navy, whereas most of the people on the materiel side looked at it as a toy, a Cousteau toy. We had a big tent down there and it was getting a lot of publicity. It was an inner space program and so forth. I was looking at it because I thought we would need to be able to use a man, on occasion, and not just a remote sensor. I didn't know. I wasn't smart enough to know what that occasion would be. But today, it has been proved true. In the intelligence world, it is absolutely true.

INTERVIEWER: Well, that is true even in the operational world. The SUPSALV gets calls all the time, not only from various agencies in the United States, but also from overseas. Could assistance be rendered in locating and retrieving something? I think that the retrieval of the bomb was a demonstration of the early success of the program that Dr. Wakelin had initiated.

ADMIRAL SNYDER: You're absolutely right, and I think we proved it to the world. But I don't think the Navy understood that. Except for what the contractors brought, all the gear that was out there, the diving suits, submersibles, the CURV and so forth, were all in-house Navy equipment. They weren't combat ships, but they were paid for and owned by the United States Navy. The equipment was designed and developed by the United States Navy or its university and

laboratory contractors. I mean, the *Alvin* was named for Alvin Vine at Woods Hole, but the Navy paid for it and the Navy stood over it.

INTERVIEWER: I remember that the SUPSALV recently gave a speech. It was when an airliner was lost off Los Angeles. He said, "We have put our resources to work. It may take a couple of weeks, but I am positive that we will find the flight recorder." Then, someone handed him a note and he read it out loud, "We found it an hour ago and it is being taken aboard our surface ship."

ADMIRAL SNYDER: I think that demonstrates what I was trying to do. But I didn't have that much luck with Supervisor of Salvage. I think the SUPSALV people always thought somebody was getting into their knickers. The Supervisor of Salvage has a unique function, authorized by Congress, which allows him to do a lot of things from an operational viewpoint that nobody else in the Navy can do. Working for the assistant secretary, or later as the oceanographer, I never saw that the oceanography program was in competition with them. We actually worked to be sure that the Supervisor of Salvage had the capability both in ships and in manpower for Man in the Sea. I use the term 'Man in the Sea' because that was the term I learned when we first started talking to Captain Cousteau. I do not think people understood that when the assistant secretary's staff was five people plus a naval aide, a Marine aide and a bunch of GS-13 to 15 secretaries. We weren't trying to take on any more responsibilities. We were trying to get rid of them. I don't know what kind of staffing is there now, but I guarantee you that it's a whole lot more than five people.

INTERVIEWER: When we talked last week, you said that the Navy had to grow into a new capability. Bill Searle's vision in the 1960s was to have a Director of Ocean Engineering over a Supervisor of Salvage and a Supervisor of Diving. Looking back, we can now see that they had

enough successes over the last forty years to breed a new outlook. They take great pride in their offices, accomplishments and parts in the Navy's current remarkable undersea capabilities.

ADMIRAL SNYDER: They're taking pride in doing something for people other than just those in the Navy. The resentment that I faced, working for the assistant secretary, was in promoting the concept that the Navy had an obligation, just as we have for the rescue of people at sea.

International law states that except when being shot at in time of war, a naval vessel must stop what it is doing and go to rescue a merchant ship. The Navy didn't like that. They didn't that the oceanographer was sending people to find a pistol in Lake Michigan or doing what you are

talking about. Now, what you're telling me is that they understand the value of this, because the Navy is not big enough to do its own job. In fact, there's a piece of paper over there on my desk.

In it, someone talks about how important I felt it was to have people help the Navy, because our job was otherwise impossible. I felt that way both while I was working for the assistant secretary and as the oceanographer. If you wanted to, you could spend the Navy's whole budget to

understand how to operate in, on, under and above the world's oceans. I used to be criticized for going down with the oil companies and giving them even unclassified information, but they were

helping us more than we were helping them because they had the money. They were going to

find oil. That paid money. I think that when Bill Searle came, he began to see the ability of the

Supervisor of Salvage. He recognized that it wasn't a bad thing to help other people out because

the Supervisor of Salvage does get reimbursed. It wasn't like the oceanographer. If I got paid, I

didn't care. The Supervisor of Salvage kept a real hard set of books with regard to what he did

for other people. But I think the Supervisor of Salvage was, in a sense, and maybe Bill would

disagree, an independent agency and not part of the bureau.

INTERVIEWER: Yes. I agree with you completely. He had an office in New York and a source of funds, which you just indicated, that permitted him to do some expensive things. But he said, "Don't worry about the cost. We will budget for it next year. We are going to set a precedent and then, we can continue doing it." I think that Bill Searle was the first Supervisor of Salvage who, as I saw it, recognized the Navy's responsibility to people and to the world's oceans. He's a great man. We've been talking about the Office of the Oceanographer and the Navy's oceanographic program. They had a very important role over a long period of time in making this all come together. But could you catalog what was involved, the oceanography, Navy weather and all the things that were included?

ADMIRAL SNYDER: I saw the creation of the Oceanographer of the Navy before I myself became the Oceanographer of the Navy, and I never wanted that job, by the way. I wanted to go to sea and stay at sea. But it didn't turn out that way. As the office in the Navy that gave the Navy the ability to operate, technically, scientifically and operationally in, on, under and above the world's oceans, it has a big view. People would say, "Well, is that true?" My reply was, "If I can tell you how the Mark 48 torpedo is going to operate so that you can use one instead of four to hit the target, then I have proven it to you." But they weren't willing to pay for it. Even Admiral Bob Long, when he was head of submarines wasn't willing to pay for it. Even Admiral Wilkinson was perfectly willing to support me but wasn't always willing to pay for it. I remember having one discussion that basically said, do I think that what I'm asking for is competing with him getting a billion dollar submarine? I said, "Come off it." I understood the competition in the Navy for dollars. I did not expect to get completely what was needed to do this job, but I to be able to do as much as we could to help out. Toward the end, people stopped

criticizing me for being willing to support other agencies. By the time I became the oceanographer, though I can't remember the exact details, I was the special assistant to the director of the National Science Foundation. I was the special assistant to the Secretary of Commerce. I was the special assistant to the Vice Commandant of the Coast Guard. I was the special assistant to the Interior Department. I even let his oceanographic-type ships use our facilities. He didn't reimburse the Navy, but the government didn't have to hire a big expensive bureaucracy to get the work done. I can't remember all the others.

INTERVIEWER: Was that the work with the Geological Survey?

ADMIRAL SNYDER: Yes. That was who it was. There was an internal feud in the government over whether the Geological Survey from Interior would be more of an ocean-oriented thing or if NOAA would be a more ocean-oriented thing. NOAA was only a hydrographic group. It really wasn't anything else, but it got into it in a lot of ways. I'm pretty familiar with that because while I was working for the assistant secretary, I was assigned many times to work with Athelstan Spielhaus, the guy who was always drunk and wrote that comic strip. He was the one who started the Sea Grant program, politically. That was after Bob Abel got hired. In fact, I remember a call from the National Science Foundation Director. The Sea Grant program went to the NSF before it was given to NOAA. I can remember his call because he said, "Snyder, I need to talk to you privately. Get off the squawk box. I'm thinking of hiring Bob Abel to run the Sea Grant program. What do you think?" I said, "That's fine, but keep your line on him." He laughed and said, "Thanks for the tip." Bob Abel is very capable, but I think that you always had to be sure of who was running the program, generally. I don't mean the nuts and bolts. When they moved the program from the Science Foundation to NOAA, Bob continued there. We were very close

friends. Bob had been the executive director or secretary of the Interagency Committee on Oceanography, which was established by my boss back in the early 1960s. I got to know him really well. Even now, we see each other once or twice a year. But the Sea Grant program became a political thing, as I see it, in the eyes of certain members of Congress and certainly in the university's eyes. It was Uncle Sam passing out more money, wasn't it?

INTERVIEWER: I think it was deliberately seeded to universities scattered across the United States in order to build up its representation in Congress.

ADMIRAL SNYDER: Of course. They did it just like the Post Office and the Weather Bureau. The Weather Bureau saw to it that there was a representative of the United States Weather Bureau in every town that had a member of Congress in it, whether that town needed a weather station, for the same reason. I used to testify both when I was young and while I was the oceanographer along with Dr. Bob White or anybody else who wanted to talk about the oceans, oceanography, sea business, Man in the Sea or fishing and that kind of stuff. In those days, they liked to have a naval officer sitting beside them. I've even gone and done something quasi-legal by doing television promotions with members of Congress who are on those committees. The fine line says you can't deal with members of Congress unless they are your representatives or the Navy Office of Legislative Affairs has told you to that you can. But in many parts of the country, a guy enjoys having an admiral standing up beside him when he's making his speech.

INTERVIEWER: Did you know that in France, naval officers are forbidden to leave the country when a national election is going on?

ADMIRAL SNYDER: Oh, no. That's fascinating. The navies of South America are political but aren't generally involved in coups. It's usually the armies and air forces that is involved, while

the navies sit and pretend that they are above it all.

INTERVIEWER: I think this restriction applies to army and air force in France also, and to all military officers.

ADMIRAL SNYDER: I always thought it was very interesting. Here I am. I've been in the weapons system program. I've been at Los Alamos. I've been at Livermore. I've been at Sandia Base. I've been the program manager for the Polaris warhead and reentry body on-site. The only thing I had to do with oceanography in those days was to be sure that we knew where the FBM submarine was and whether it could launch a missile through the interface of the ocean into the air. Then, all of a sudden, I was the Oceanographer of the Navy. That started really because of my job in the assistant secretary's office. Yet, I don't think history will ever give Jim Wakelin true credit for the fact that we have a Navy oceanographic program only because of him. Morse followed through and indeed, did more in certain areas. Frosch did much more in other areas. But I'm talking about getting it started. We were dumping money in every small town and university that was willing to accept it from ONR in order to get involved in the ocean business. We suddenly woke up to the fact that in the Navy, certain programs, like anti-submarine warfare and submarine operations, needed to know a lot about the ocean. The Polaris program put us in the position of having to really understand something more about the ocean than most people recognize.

INTERVIEWER: Now, I see the direct connection between OP-95 anti-submarine warfare and ASN for R&D.

ADMIRAL SNYDER: When I walked into that Pentagon debate on the subject of anti-submarine warfare, I remember Secretary Wakelin saying to me, "You know, Eddie, the

Congress is really pushing us on anti-submarine warfare. They say we don't have any capability, and I tend to agree with them. I want to see what we should do. They want us to have a czar of anti-submarine warfare. The Navy does not want us to do that. The Navy doesn't want to push ASW in the same limelight as tailhooking, driving nuclear submarines and so forth." He got me involved with that. Congress really pushed us into anti-submarine warfare. I woke up walking in there, coming from command of a destroyer, not yet aware of the SQS-26 sonar, and all of a sudden, I was, in effect, advising the secretary as to how to do it, pay for it, train people and get people interested in it. I should have known a lot more about it than I did. I was running some ASW programs but was not up to date on all the new stuff.

INTERVIEWER: But I think the current ASW capability is another success story in the Navy's oceanographic scientific program.

ADMIRAL SNYDER: Well, I would say it is more to the scientific program than the oceanographic program because it occurred prior to the establishment of a valid oceanographic program. My personal opinion is that the kinds of things that we've done, plus what the oil companies were able to do later with it, really started at the Office of Naval Research. The big problem, as I saw it when I came in, was how we were to move it from ONR to new ships. In other words, the question was how we were to take it from the drawing board and the bread board model to something the Navy could use at sea. I was a sea driver, so I'm a unique individual. I don't think you'll see that again. I had command at sea of three ships and at other times, I managed three or four technical programs. Nowadays, you've got to make a decision to go one way or the other. But I was lucky in a sense and maybe unlucky in another, because I would rather have been an operator. It was more fun. I couldn't explain or articulate to you the

fun of commanding a battleship, seeing peoples' lives saved, and seeing very scary people just disappearing whenever you moved in. That was a real thrill. It was like a surgeon saving somebody's life. It got to be a real satisfaction when you knew you made the right cut or the right diagnosis. I'll never get that opportunity and I don't think many other people will, either. But that's beside the point. Stop and ask yourself, how do you get anything done in the Washington area? I remember the paper I wrote at the War College, "The Five Sided No-Sayer," meaning the Pentagon. They can't do anything but say no. I really verified that after I got there. I would see sometimes as many as 12 flag officers' signatures on a piece of paper before it got to the Secretary of the Navy. That was ridiculous. I think it was ridiculous.

INTERVIEWER: Tell me about taking all the various components of your program and moving them down to Bay St. Louis?

ADMIRAL SNYDER: That resulted from a directive by the Congress of the United States for the Navy to move X number of people out of the Washington, D.C. area. I don't know how they stated it, but it was to move like a minimum of 10,000 people away from the so-called 'greater Washington area.' It was probably led, in fact, I'm pretty sure it was led, by Representative Sikes of Florida. His motive, in my opinion, was to relocate some of it into his district. If you remember, Panama City got a lot. It was resisted but it got a lot. When I came back as the oceanographer, I reported to the Assistant Secretary for Research and Development, as well as to the vice chief and a few other flag officers. Dr. Potter had been involved in the ocean engineering business with General Motors (GM). He had done some tremendous things, was really fascinated with it, and was very capable. He was the director of the GM laboratories. All of a sudden, he called me in and said, "Ed, I want you to move the oceanographic program away

from Suitland. You go find out where to move it." I went on a hunt and it wasn't long before the word got out. You don't go to Senator Hollings' area and ask the kind of questions I was asking without Senator Hollings, who's in that kind of business, saying, "What's that snappy young admiral doing there? What does he want? I understand he's in this ocean business." That was also happening out in Seattle, Washington, because I was only going to the coastal states. I was not going to Illinois or to West Virginia, for sure. I had no political purposes, but other people influenced me. It was other people who found Mississippi and New Orleans. They found the NASA base there. Dr. Frosch, by the way, became the director of NASA and used to ask me to go down with him when he would talk about this huge facility down there. It's 25 miles in radius and carved out of nowhere. Everybody in Mississippi wanted to do something else with the site, but NASA needed to have it as a stand-by place to build explosives and so forth. It's empty and free, basically. It's on the water and next door is a computer site to handle all the computers for meteorological, oceanographic and charting data. Also, over in New Orleans were other free, open buildings. I went back and reported all of this to Dr. Potter privately. The next thing I knew, I got an order to examine the possibility of moving the Bureau of Naval Personnel to New Orleans. Well, I looked at the boss and said, "You don't want me to do that. You don't understand." Navy officers then, in the early 1970s, did not know how to confront anybody on the telephone. They had to see them eyeball to eyeball, and they were never going to let you take personnel control out from under their eyesight. He said, "Ed, you didn't hear me." Of course, I went over and told Congressman Hebert, who was a very powerful guy, what I wanted to do. I asked if he would support it and he said, "Yeah, I think we can do that." To make a long story short, though, it didn't happen and I had to go back and tell him. He treated me okay. He was

very good about it. Congressman Hebert was not one of these people who said, "Get it out of Washington." He was pretty good. You've got to realize that I had told him I was going to put the whole Navy personnel office down in all these empty buildings in the New Orleans area. Then, I came back and told him that I couldn't. He didn't appreciate it, but he treated me nicely. He treated me very well whenever I went there. I remember going there once with Jim Hannahan, the one black man I had on my staff. The Congressman was taking us to some exclusive club for dinner, but club policy was that no blacks were permitted. This was thirty years ago, when it was still common practice in many places. I told Congressman Hebert that it might be a problem. He said, "I am on the board, and I will change the rules." We walked up to the club and had our dinner.

INTERVIEWER: Good.

ADMIRAL SNYDER: That was Hebert. I guess he had never paid attention to it before. Once, I said something to him, bang. Things happened when he'd say something in the State of Louisiana. Little things like that were always fascinating to me, because he was a real gentleman and a man of his word. Senator Stennis was also a man of his word. The other person I dealt with a lot was Senator Magnuson. I dealt with him while I worked with the assistant secretary, and Magnuson was wonderful. I shouldn't say this, but in my opinion, he was an alcoholic. In fact, I used to get assigned to go to parties with him. When the secretary would go to a party, he'd say leave me and go follow him. I didn't know what alcohol is and only lately I've learned that we have alcoholics in a lot of professions. I guess I was fortunate.

INTERVIEWER: Let me go back to Bay St. Louis, where the computer was a NASA computer. Did you have to buy a new one, or did the Navy enlarge the NASA computer after they arrived?

ADMIRAL SNYDER: I bought a new one because I wanted the world's best computer. The only good one the Navy had was over at the Naval Research Laboratory, but it was too technical a computer. It wouldn't handle the kinds of things you have to deal with in meteorology and oceanography. We did have another computer in Monterey on the west coast. As a matter of fact, in the 1960s and 1970s, the most competent Navy officers, not civilians, in the computer world were the oceanographic and meteorology people. They were running this computer facility out in Monterey. I had already planned for a new computer in my budget, whether we moved or didn't move, to handle what I could see coming down the road for the next ten years. It was approved after I left, but those things take a long time. I'm not sure whether the assistant secretary thought it was a power grab, or what kept holding it up, but I did have the General Services Administration's approval and the OMB's approval, and in those days, it was hard to get computer approval. But I had all the approvals except within the Navy. That was slowing it down.

INTERVIEWER: They drag their feet. First, it was air conditioning. We had to go through hoops to get air conditioning for our buildings. Then, it was computers. I don't know what it is now.

ADMIRAL SNYDER: It was also perfectly clear that if you really wanted to tie all of that stuff together, you had to do it within the ability to have it classified. You might disagree with that. A lot of people do. But it was true. You had to be able to classify it when you needed it classified. Yes, I gave everything to everybody. Yes, I gave things to the Soviet Union. But certain people in the military departments, the Department of Defense and the Navy, particularly the civilians, understood that the United States came first in my mind, but I didn't over-classify. As a matter of fact, I remember walking into an argument that took place while Secretary Nitze was Secretary

of the Navy. It was over the issue of the Transit Navigational System. The Transit Navigational System, using a satellite system, played a part in telling the Polaris when to fire. Its other role was purely navigational. Well, I gave the Soviet technical people the navigational part of it and of course, that blew a lot of peoples' minds. They didn't see Transit as just a navigator. They saw it as a Navy weapons program. I remember throwing down a South African paper article about the Transit in front of the desk with all these admirals. I said, "Who the heck are we trying to keep it from? Here's a declassified version from South Africa. I'm talking about navigation." Before the Global Positioning System (GPS) became available to everybody in the world, Transit was a heck of a fight. But it probably set the stage so that GPS later did not have to go through that same fight. The United States Navy did permit industrial receivers the capability to use the Transit Navigational System, but again, that was over strenuous objections.

INTERVIEWER: What was the Transit system?

ADMIRAL SNYDER: It was a satellite system used to navigate before the GPS, which we needed for the Polaris program. It was the predecessor to the GPS. The big issue was over whether we improved and increased the number of Transits or created a new system. The decision made by the Secretary of Defense to do a new system. I was involved with the GPS when it first came out, and I was supporting it. I think the only thing wrong with it was the altitude. The third thing the GPS can give you is absolutely accurate altitude. Well, so what? Simple radar gives you the inches you are above the building, the earth, or anything else. The GPS only gives you altitude above a geodetic position. I'm sure they have that capability, but what good was that to me? It's a three-dimensional navigation system but you don't need to know feet above anything.

INTERVIEWER: They proposed using it for hands-off landing of aircraft. For that, you would even have to integrate the polar wobble.

ADMIRAL SNYDER: In that case, they would need to know the feet. I'm not sure that the technical details are available to the rest of the world. They will be, eventually, because you can't hide that forever. Then, I didn't see that it was that important, from a navigational viewpoint. I think it's just fascinating. I remember in the early part of the Polaris program, when I was the warhead officer. I was also double-hatted to the Atomic Energy Commission and Livermore, to Dr. Teller. In addition to the other problems, you had to know where you were. If you didn't, you were going to miss. In those days, we didn't have the smart bomb ability to sense a specific target and go after it. We had to know where we were and where the target was and do both geodetically, since we were operating in geodetic space. How do you rectify and resolve all of those issues when the Navy says to you, "We know where we are within feet?" You've got admirals asking you, "What are you talking about?" or saying "That's a waste of money." I went to the Naval Academy. I know how to blah, blah, blah. I said, "Okay, we've got a really simple problem. Let us put out an order that when the Sixth Fleet returns from its next deployment, no ship can talk to any other about its position. I don't want the admiral given the noon position from the ships. He can get that from his flagship, but not from the rest of the fleet. When we come back, we'll look at them, and I guarantee you that they will average more than ten miles apart." They were 18 miles apart or something like that. That was not accurate enough for a missile to launch against a target in those days. The need for having a navigational system became obvious. Forget the business of all the old Navy guys being able to use a sextant. I think they had their picture taken with sextants but never really knew how to use them anyhow.
